NONNEGATIVE RICCI CURVATURE
AND MINIMAL GRAPHS WITH LINEAR GROWTH
NONNEGATIVE RICCI CURVATURE
AND MINIMAL GRAPHS WITH LINEAR GROWTH

GIULIO COLOMBO, EDDYGLEDSON S. GAMA, LUCIANO MARI AND MARCO RIGOLI

We study minimal graphs with linear growth on complete manifolds $M^m$ with Ric $\geq 0$. Under the further assumption that the $(m-2)$-th Ricci curvature in radial direction is bounded below by $Cr(x)^{-2}$, we prove that any such graph, if nonconstant, forces tangent cones at infinity of $M$ to split off a line. Note that $M$ is not required to have Euclidean volume growth. We also show that $M$ may not split off any line. Our result parallels that obtained by Cheeger, Colding and Minicozzi for harmonic functions. The core of the paper is a new refinement of Korevaar's gradient estimate for minimal graphs, together with heat equation techniques.

1. Introduction

The theory of entire minimal graphs in Euclidean space $\mathbb{R}^m$, that is, of functions $u : \mathbb{R}^m \to \mathbb{R}$ solving the minimal (hyper-)surface equation

$$\text{div}\left(\frac{Du}{\sqrt{1 + |Du|^2}}\right) = 0$$

(MSE)

is built upon the following foundational results:

(1) The Bernstein theorem: solutions to (MSE) are all affine if and only if $m \leq 7$.

(2) For each $m \geq 2$, positive solutions to (MSE) are constant.

(3) For each $m \geq 2$, solutions to (MSE) with at most linear growth on one side are affine (i.e., the Hessian $D^2 u \equiv 0$).

Here, $u$ is said to have at most linear growth on one side if, up to changing the sign of $u$,

$$u(x) \geq -C(1 + r(x))$$

holds on $\mathbb{R}^m$ for some constant $C > 0$, where $r$ is the distance from a fixed origin. The validity of (1) is due, as well-known, to the combined effort of S. Bernstein [1915] ($m = 2$, see also [Mickle 1950; Hopf 1950]), W. H. Fleming [1962] (still for $m = 2$), E. De Giorgi [1965] ($m = 3$), F. Almgren [1966] ($m = 4$), J. Simons [1968] ($m \leq 7$) and E. Bombieri, De Giorgi and E. Giusti [Bombieri et al. 1969a] (counterexamples if $m \geq 8$). On the other hand, (2) and (3) were both proved by Bombieri, De Giorgi and M. Miranda [Bombieri et al. 1969b] for $m \geq 3$; in particular, (3) refines J. Moser's theorem [1961], which states that $u$ is affine provided that $|Du| \in L^\infty(M)$. Further properties of entire minimal graphs in Euclidean space were obtained by Bombieri and Giusti [1972]: among them, we mention the fact that $u$ is

MSC2020: primary 53C21, 53C42; secondary 31C12, 53C24, 58J65.

Keywords: Bernstein theorem, splitting, minimal graph, Ricci curvature, tangent cone.

affine whenever \( m - 1 \) of its partial derivatives are bounded. The result was improved in recent years by A. Farina [2015; 2018], who showed that \( u \) is affine if \( m - 7 \) partial derivatives of \( u \) are bounded on one side. Further enhancements of Moser’s result, proving that \( D^2 u \equiv 0 \) by only assuming that \( |Du| = o(r) \) as \( r(x) \to \infty \), were obtained in [Caffarelli et al. 1988; Ecker and Huisken 1990; Simon 1989]. We also mention the recent [Farina 2022], where the rigidity of a minimal graph is obtained by assuming that an upper level set contains, or is contained in, a half-space.

In a Riemannian setting, it is natural to ask the following:

**Question 1.** For which classes of complete Riemannian manifolds \( M \) one could expect results like (B1), (B2), (B3)?

The problem motivated our previous works [Bianchini et al. 2021b; Colombo et al. 2022], as well as the present paper. Recall that a solution to (MSE) on a Riemannian manifold \((M^m, \sigma)\) gives rise to a graph

\[
F : M \to \mathbb{R} \times M, \quad F(x) = (u(x), x),
\]

which is minimal if the ambient space \( \mathbb{R} \times M \) is endowed with the product metric \( dt^2 + \sigma \). Hereafter, we say that the graph is entire if \( u \) is defined on the whole of \( M \).

If \( M \) is close to hyperbolic space \( \mathbb{H}^m \), namely, \( M \) is a Cartan–Hadamard manifolds with suitably pinched negative curvature, (B1), (B2), (B3) drastically fail, since each continuous function on the boundary at infinity of \( M \) can be attained as the limit value of an entire minimal graph, which is therefore bounded. An exhaustive literature on the problem can be found in the survey [Heinonen 2021]; see also the introduction of [Bianchini et al. 2021a].

Denoting by \( g = F^*(dt^2 + \sigma) \) the graph metric and with \( \Delta_g \) its Laplace–Beltrami operator, (MSE) can be written as \( \Delta_g u = 0 \), making contact with the theory of harmonic functions. In Euclidean space \( M = \mathbb{R}^m \), (B2) and (B3) hold as well when considering harmonic functions instead of solutions to (MSE), while the analogy fails for (B1) since there is no rigidity for entire harmonic functions without imposing any growth condition. This suggests that, for (B2) and (B3), an answer to the above question may be guided by the global behavior of harmonic functions on Riemannian manifolds, according to which it is natural to consider the problem on manifolds satisfying either

\[
\text{Sec} \geq 0 \quad \text{or} \quad \text{Ric} \geq 0,
\]

where Sec, Ric are the sectional and Ricci curvatures of \((M, \sigma)\). Indeed, if \( \text{Ric} \geq 0 \), positive harmonic functions on \( M \) are constant, by S.Y. Cheng and S.T. Yau’s gradient estimate [Yau 1975; Cheng and Yau 1975], while a harmonic function with linear growth forces any tangent cone at infinity of \( M \) to split, by work of J. Cheeger, T. Colding and W. Minicozzi [Cheeger et al. 1995]. Furthermore, \( M \) itself splits off a line if \( \text{Ric} \geq 0 \) is strengthened to \( \text{Sec} \geq 0 \) (see [Antonelli et al. 2022] for a complete proof), or if \( M \) is parabolic (see [Li and Tam 1989] and Remark 5 below).

In view of the convergence theory developed in the past 50 years for manifolds with \( \text{Sec} \geq 0 \) or \( \text{Ric} \geq 0 \), some of the tools used to prove the Bernstein theorem in \( \mathbb{R}^m \) are available on manifolds satisfying (1), making these assumptions a natural setting also for the study of (B1). However, much has to be done
and (B1) seems very challenging to prove even on manifolds with $\text{Sec} \geq 0$. In fact, we are aware of no results in this direction.

The situation is different for (B2) and (B3), for which, as we shall detail below, the main difficulty is to prove the results by only requiring $\text{Ric} \geq 0$, arguably the sharp condition for their validity (in this case, however, (B3) has to be suitably weakened, see later).

Regarding (B2), after previous work by H. Rosenberg, F. Schulze and J. Spruck [Rosenberg et al. 2013], a complete answer was obtained by the first, third and fourth authors together with M. Magliaro [Colombo et al. 2022], and independently by Q. Ding [2021a] with different methods:

**Theorem 2** [Colombo et al. 2022; Ding 2021a]. Connected, complete manifolds $M$ with $\text{Ric} \geq 0$ satisfy (B2); that is, entire positive minimal graphs over $M$ are constant.

In this paper, we address (B3). In view of the result in [Cheeger et al. 1995], it is reasonable to formulate the following:

**Conjecture 3.** Let $M$ be a connected, complete manifold with $\text{Ric} \geq 0$ and possessing a nonconstant entire minimal graph with at most linear growth on one side. Then, every tangent cone at infinity of $M$ splits off a line.

The problem seems to be considerably harder compared to the case of harmonic functions. We are aware of only two results in the direction of Conjecture 3. Ding, J. Jost and Y. Xin [Ding et al. 2016] proved that $\mathbb{R}^m$ is the only manifold satisfying the following assumptions:

\[
\text{Ric} \geq 0, \quad \lim_{r \to \infty} \frac{|B_r|}{r^m} > 0, \quad \text{(2.}\alpha) \\
\text{the curvature tensor decays quadratically} \quad \text{(2.}\beta)
\]

and admits an entire, nonconstant minimal graph with at most linear growth on one side. Very recently, Ding [2021b] posted on arXiv a paper where he proved Conjecture 3 on manifolds satisfying the assumptions in (2.α). The bulk of his argument is to show the remarkable property that the isoperimetric inequality, satisfied by $(M, \sigma)$ in view of (2.α), is inherited by the graph of $u$. This allowed Ding to adapt, in a nontrivial way, tools from [Bombieri et al. 1969b; Bombieri and Giusti 1972] and from Cheeger–Colding theory to reach the goal. We stress that his method heavily depends on the Euclidean volume growth condition in (2.α).

In our work, we address Conjecture 3 without requiring the Euclidean volume growth assumption, but rather a mild further curvature condition. To formulate our main result, we first recall the definition of the $\ell$-th Ricci curvature:

**Definition 4.** Let $(M, \sigma)$ be a manifold of dimension $m \geq 2$. For $\ell \in \{1, \ldots, m-1\}$, the $\ell$-th (normalized) Ricci curvature is the function

\[
v \in T_x M \mapsto \text{Ric}^{(\ell)}(v) = \inf_{\mathcal{W} \subseteq v^\perp, \dim \mathcal{W} = \ell} \left( \frac{1}{\ell} \sum_{j=1}^{\ell} \text{Sec}(v \wedge e_j) \right),
\]

where $\{e_j\}$ is an orthonormal basis of $\mathcal{W}$.
The function $\text{Ric}^{(\ell)}$ interpolates between the sectional and Ricci curvatures, obtained respectively for $\ell = 1$ and, up to the normalization constant $m-1$ for $\ell = m-1$. In particular, with our chosen normalization the following implications are immediate:

$$\text{Sec} \geq c \implies \text{Ric}^{(\ell-1)} \geq c \implies \text{Ric}^{(\ell)} \geq c \implies \text{Ric} \geq (m-1)c.$$ 

Hereafter, given $H \in C([0, \infty))$ and denoting by $r$ the distance from a fixed origin $o \in M$, we use the short-hand notation $\text{Ric}^{(\ell)}(\nabla r) \geq -H(r)$ on $M$ to mean the inequality

$$\text{Ric}^{(\ell)}(\nabla r(x)) \geq -H(r(x)) \quad \text{for all } x \in M \setminus \{o\} \cup \text{cut}(o),$$

where $\text{cut}(o)$ is the cut-locus of $o$.

A relevant class of manifolds for which rigidity holds without imposing any growth of $u$ is that of parabolic ones. Recall that a manifold $M$ is said to be parabolic if every positive superharmonic function on $M$ is constant.

**Remark 5.** By work of N. Varopoulos [1981] and Li and Yau [1986], if $\text{Ric} \geq 0$ the parabolicity of $M$ is equivalent to

$$\int_{B_s}^\infty \frac{s \, ds}{|B_s|} = \infty, \quad (3)$$

where $B_s$ is a geodesic ball centered at a fixed origin $o$. Indeed, (3) is sufficient for the parabolicity of a complete manifold, independently of any curvature requirement; see [Grigoryan 1999].

Lastly, we recall that a tangent cone at infinity for a complete (noncompact) manifold $M$ is any metric space obtained as a blow-down of $M$. More precisely, a pointed metric space $(X_\infty, d_\infty, x_\infty)$, $x_\infty \in X_\infty$, is a tangent cone at infinity for $(M, \sigma)$ if, for some base point $x \in M$ and some sequence $\{\lambda_n\}$ of positive real numbers such that $\lambda_n \to \infty$, one has

$$(M, \lambda_n^{-1} \text{dist}_\sigma, x) \to (X_\infty, d_\infty, x_\infty)$$

in the pointed Gromov–Hausdorff (pGH) sense. If $(M, \sigma)$ has nonnegative Ricci curvature, then tangent cones at infinity exist based at any point $x \in M$, by Gromov’s precompactness theorem [2007].

We are ready to state:

**Theorem 6.** Let $(M, \sigma)$ be a connected, complete Riemannian manifold of dimension $m \geq 2$ with $\text{Ric} \geq 0$, and let $u \in C^\infty(M)$ be a nonconstant entire solution to (MSE).

(i) If $M$ is parabolic, then it admits a splitting $M = N \times \mathbb{R}$ with the product metric $\sigma_N + ds^2$ for some complete manifold $N$ with $\text{Ric}_N \geq 0$ such that in the variables $(y, s) \in N \times \mathbb{R}$ it holds $u(y, s) = as + b$ for some $a, b \in \mathbb{R}$.

(ii) If $M$ is nonparabolic and

- $u$ has at most linear growth on one side,
there exists an origin \( o \in M \) such that, denoting by \( r \) the distance from \( o \),

\[
\text{Ric}^{(m-2)}(\nabla r) \geq -\frac{\tilde{\kappa}^2}{1+r^2} \quad \text{on } M,
\]

for some constant \( \tilde{\kappa} \geq 0 \),

then every tangent cone at infinity of \( M \) splits off a line.

**Remark 7.** In case (i), the claimed splitting \( M = N \times \mathbb{R} \) for which \( u \) is independent of \( N \) may not be the unique splitting of the manifold as a product of a line and a complete manifold, as the case of affine graphs on \( M = \mathbb{R}^2 \) shows. In case (ii), since \( M \) is nonparabolic then necessarily \( m \geq 3 \) (see below), so \( \text{Ric}^{(m-2)} \) is well-defined. In the statement of (ii), we also emphasize that tangent cones at infinity may be based at any point of \( M \), not necessarily at \( o \).

Case (i) in Theorem 6 is easy to obtain, and might be well-known among specialists. We included it for the sake of completeness. Regarding case (ii), the curvature condition in (4) is only used to infer that \( u \) has bounded gradient on \( M \). In other words, as a consequence of our proof we obtain a generalization of Moser’s result [1961] to the following:

**Theorem 8.** Let \( M \) be a connected, complete manifold with \( \text{Ric} \geq 0 \). If \( u \) is a nonconstant solution to (MSE) and \( |Du| \in L^\infty(M) \), then every tangent cone at infinity of \( M \) splits off a line.

It was already observed in [Cheeger et al. 1995] that a manifold \( M \) with \( \text{Ric} \geq 0 \) may not split off any line despite each of its tangent cones at infinity does. A counterexample was constructed in [Kasue and Washio 1990], and building on it we get the following result:

**Proposition 9.** For \( m \geq 4 \), there exists a connected, complete manifold \( M \) with

\[
\text{Ric}^{(2)} \geq 0, \quad \text{Ric} > 0, \quad |\text{Sec}| \leq \tilde{\kappa}^2
\]

for some constant \( \tilde{\kappa} > 0 \), which carries a nonconstant minimal graph \( u : M \to \mathbb{R} \) with \( |Du| \in L^\infty(M) \).

Note that \( \text{Ric}^{(m-2)} \geq 0 \) and that, having positive Ricci curvature, \( M \) does not split off any line. Whence, in assumption (ii) of Theorem 6 the conclusion cannot be strengthened to a splitting of \( M \) itself, at least if \( m \geq 4 \).

When \( \text{Sec} \geq 0 \), however, the above phenomenon does not happen. Leaving aside dimension \( m = 2 \), covered by case (i) in Theorem 6, we obtain

**Corollary 10.** Let \((M, \sigma)\) be a connected, complete Riemannian manifold of dimension \( m \geq 3 \) satisfying \( \text{Sec} \geq 0 \). If there exists a nonconstant entire solution \( u \in C^\infty(M) \) of (MSE) with at most linear growth on one side, then \( M \) admits a splitting \( M = N \times \mathbb{R} \) with the product metric \( \sigma_N + ds^2 \) for some complete manifold \( N \) with \( \text{Sec}_N \geq 0 \) such that in the variables \( (y, s) \in N \times \mathbb{R} \) it holds \( u(y, s) = as + b \) for some \( a, b \in \mathbb{R} \).

The corresponding problem for harmonic functions was also studied by A. Kasue [1990]. Corollary 10 relates to the results obtained by P. Li and J. Wang [2004]. There, the authors study connected, complete, stable minimal hypersurfaces \( \Sigma \to \overline{M} \) properly immersed into a complete manifold \( \overline{M} \) whose sectional curvature is nonnegative, and prove that either \( \Sigma \) has only one end or \( \Sigma \) is a totally geodesic cylinder \( P \times \mathbb{R} \).
for some compact manifold $P$ with nonnegative sectional curvature. Our setting falls into their framework, since a minimal graph in $\mathbb{R} \times M$ is stable, properly embedded and $M = \mathbb{R} \times M$ has nonnegative sectional curvature. However, our conclusion is stronger, since it allows $M$ to have only one end and it also implies a splitting of $M$ itself.

To conclude, we prove the next result for graphs with slower than linear growth on one side, that should be compared to [Ding et al. 2016, Theorem 3.6; 2021b, Theorem 1.4].

**Theorem 11.** Let $(M, \sigma)$ be a connected, complete Riemannian manifold of dimension $m \geq 2$ with $\text{Ric} \geq 0$, and let $u \in C^\infty(M)$ solve (MSE) on $M$ and satisfy

$$
\lim_{r(x) \to \infty} \frac{u_-(x)}{r(x)} = 0,
$$

where $u_-(x) = \max\{-u(x), 0\}$. Assume that either

- $M$ is parabolic, or
- $M$ is nonparabolic and there exists an origin $o \in M$ such that, denoting by $r$ the distance from $o$,

$$
\text{Ric}^{(m-2)}(\nabla r) \geq -\frac{\tilde{\kappa}^2}{1 + r^2} \quad \text{on } M,
$$

for some constant $\tilde{\kappa} \geq 0$.

Then, $u$ is constant.

**Remark 12** (more general curvature bounds). It is natural to wonder whether conditions $\text{Ric} \geq 0$ or $\text{Sec} \geq 0$ can be weakened still allowing for some rigidity of $u$ and $M$. In this respect we quote [Bianchini et al. 2021a, Example 3.1], where the authors constructed a manifold $M$ of dimension $m \geq 3$ with two ends, satisfying

$$
\text{Sec} \geq -\frac{\tilde{\kappa}^2}{1 + r^2}, \quad \text{vol}(B_r) \leq C r^m
$$

for constants $\tilde{\kappa}, C > 0$ and supporting a nonconstant, bounded entire minimal graph. On the other hand, the existence of such a solution to (MSE) is forbidden if $M$ has asymptotically nonnegative sectional curvature and only one end; see [Casteras et al. 2020]. An interesting class for which one might try to obtain rigidity results is that of manifolds with quadratically decaying (or asymptotically nonnegative) Ricci curvature and linear volume growth; see [Sormani 2000].

**Strategy of the proof.** Case (i) in Theorem 6 is a direct consequence of the parabolicity of $(M, \sigma)$, which in our setting can be transplanted to the graph of $u$. In particular, since every surface with $\text{Ric} \geq 0$ is parabolic, the result holds if $m = 2$, so we focus on dimension $m \geq 3$. In [Bombieri et al. 1969b], the authors obtain $(B3)$ in $\mathbb{R}^m$ via the following steps:

(a) a sharp gradient estimate, implying that a solution $u \in C^\infty(\mathbb{R}^m)$ to (MSE) with at most linear growth on one side satisfies $|Du| \in L^\infty(\mathbb{R}^m)$;

(b) an argument of [Moser 1961]: since $|Du| \in L^\infty(\mathbb{R}^m)$, for each coordinate field $\partial_j$ the partial derivative $\partial_j u$ is a bounded solution to a uniformly elliptic PDE. The global Harnack inequality implies that $\partial_j u$ is constant, which implies that $u$ is affine.
Step (b) cannot be implemented on manifolds, which in general lack parallel fields. An alternative idea was proposed in [Cheeger et al. 1995] to study harmonic functions, a blowdown argument which exploits the convergence theory of manifolds with Ricci ≥ 0. Our strategy closely follows the one in that work, and can be split into the following steps:

(a) We prove that a solution \( u \in C^\infty(M) \) to **(MSE)** with at most linear growth on one side satisfies

\[
|Du| \in L^\infty(M).
\]

(b) For fixed \( x_0 \in M \), we show that the functions \( |Du| \) and \( |D^2u| \) satisfy

\[
\lim_{R \to \infty} \frac{1}{|B_R(x_0)|} \int_{B_R(x_0)} |Du|^2 \, dx = \sup_M |Du|^2, \\
\lim_{R \to \infty} \frac{R^2}{|B_R(x_0)|} \int_{B_R(x_0)} |D^2u|^2 \, dx = 0,
\]

where \( B_R(x_0) \) is the geodesic ball of radius \( R \) and center \( x_0 \) in \((M, \sigma)\).

(c) We use the blowdown argument to guarantee the splitting of any tangent cone at infinity with base point \( x_0 \).

To be more precise, step (a) will be achieved by assuming

\[
\text{Ric} \geq 0 \quad \text{and} \quad \text{Ric}^{(m-2)}(\nabla r) \geq - \frac{\kappa^2}{1 + r^2},
\]

while (b) will be shown by requiring

\[
\text{Ric} \geq 0 \quad \text{and} \quad |Du| \in L^\infty(M).
\]

Though the strategy is the same as that in [Cheeger et al. 1995], we emphasize that the techniques in the current literature to prove (a) (respectively, (b)) do not apply under the sole assumptions in (8) (respectively, in (9)). We shall justify this claim in the next sections. Our strategy to obtain (a) is to refine a method due to N. Korevaar [1986], see Theorem 15 below, while to get (b) in our needed generality we exploit heat equation techniques, inspired by works of P. Li [1986] and L. Saloff-Coste [1992]. In this respect, we underline Theorem 27 below, yielding to (7), that in the stated generality seems to us new and of an independent interest.

2. Preliminaries

We briefly review some formulas for minimal graphs that will be used later on. In local coordinates \((x^i)\) on \( M \), the background metric \( \sigma \) and the graph metric \( g = F^*(dr^2 + \sigma) \) can be written as

\[
\sigma = \sigma_{ij} dx^i \otimes dx^j, \quad g = g_{ij} dx^i \otimes dx^j, \quad du = u_i dx^i,
\]

and \( g_{ij} = \sigma_{ij} + u_i u_j \). Letting \( \sigma^{ij} \) and \( g^{ij} \) be the components of the inverse matrices of \((\sigma_{ij})\), \((g_{ij})\), respectively, it holds

\[
g^{ij} = \sigma^{ij} - \frac{u^i u^j}{W^2},
\]
where $W = \sqrt{1 + |Du|^2}$ and $u^i = \sigma^{ij} u_j$. In general, if $\phi \in C^1(M)$ then the symbols $D\phi$ and $\nabla \phi$ will denote the gradients of $\phi$ in the metrics $\sigma$ and $g$, respectively, and in local notation we write

$$d\phi = \phi_i dx^i, \quad D\phi = \phi^i \partial_{x^i}, \quad \nabla \phi = g^{ij} \phi_j \partial_{x^i}.$$ **Differentiating the upward-pointing unit normal vector $n = W^{-1}(\partial_t - u^i e_i)$, the second fundamental form $\nabla$ in the direction of $n$ has components**

$$\nabla_{ij} = u_{ij},$$

(10)

where $u_{ij}$ are the components of the Hessian $D^2 u$ in the metric $\sigma$. Let $H = g^{ij} h_{ij}$ be the mean curvature, which we assume to vanish. Using the relation

$$0 = \Gamma^k_{ij} - \gamma^k_{ij} = \frac{u^k u_{ij}}{W^2}$$

between the Christoffel coefficients $\Gamma^k_{ij}$ of $g$ and $\gamma^k_{ij}$ of $\sigma$, for every $\phi : M \to \mathbb{R}$ the Laplace–Beltrami operator $\Delta_g$ of $g$ can be written as

$$\Delta_g \phi = g^{ij} \phi_{ij} - \phi_k u^k H W = g^{ij} \phi_{ij},$$

where we used the minimality of $\Sigma$. Also, $\Delta_g$ has the local expression

$$\Delta_g \phi = \frac{1}{\sqrt{|g|}} \partial_{x^j} (\sqrt{|g|} g^{ij} \phi_i) = \frac{1}{W} \text{div}(W g^{ij} \phi_i \partial_{x^j}),$$

(11)

where $\text{div}$ is, as before, the divergence operator in $(M, \sigma)$ and $|g|$ is the determinant of $(g_{ij})$. Next, for every Killing field $\bar{X}$ defined in $\mathbb{R} \times M$, the angle function $\Theta_{\bar{X}} = \langle n, \bar{X} \rangle$ solves the Jacobi equation

$$\Delta_g \Theta_{\bar{X}} + (\|\nabla\|^2 + \text{Ric}(n, n)) \Theta_{\bar{X}} = 0,$$

(12)

with $\text{Ric}$ the Ricci curvature of $\mathbb{R} \times M$. This is the case, for instance, of the angle function

$$\Theta_{\partial_t} = \langle n, \partial_t \rangle = W^{-1}$$

associated to the Killing field $\partial_t$. As a consequence, $W$ satisfies

$$\mathcal{L}_W W = (\|\nabla\|^2 + \text{Ric}(n, n)) W,$$

(13)

where we defined

$$\mathcal{L}_W \phi = W^{2} \text{div}_g (W^{-2} \nabla \phi) = \Delta_g \phi - 2 \langle \nabla \log W, \nabla \phi \rangle.$$ **Observe that, in terms of the metric $\sigma$,**

$$\mathcal{L}_W \phi = W \text{div}(W^{-1} g^{ij} \phi_i \partial_{x^j}).$$

(14)

If $X$ is a Killing field in $(M, \sigma)$ then we can extend it by parallel transport on $\mathbb{R} \times M$ to a Killing field $\bar{X}$ satisfying $\langle \partial_t, \bar{X} \rangle = 0$, with corresponding angle function

$$\Theta_{\bar{X}} = \langle n, \bar{X} \rangle = -W^{-1} \sigma(Du, X).$$
Since (12) holds both for \(\Theta_{\partial_y}\) and for \(\Theta_X\), it can be checked that the quotient

\[ v \doteq -\frac{\Theta_X}{\Theta_{\partial_y}} = \sigma(Du, X) \]

is a solution to

\[ \mathcal{L}_W v = 0. \tag{15} \]

We next discuss the implications of \(\ell\)-th Ricci curvature lower bounds. Hereafter, we set \(\mathbb{R}^+ = (0, \infty)\) and \(\mathbb{R}_{0}^+ = [0, \infty)\).

**Proposition 13.** Let \((M, \sigma)\) be a connected, complete manifold of dimension \(m \geq 2\) satisfying

\[ \text{Ric}^{(\ell)}(\nabla r) \geq -H(r) \quad \text{for} \quad \ell = \max\{1, m - 2\}, \]

where \(r\) is the distance from a fixed origin \(o \in M\), and \(0 \leq H \in C(\mathbb{R}_{0}^+)\). Let \(h \in C^2(\mathbb{R}_{0}^+)\) solve

\[
\begin{cases}
  h'' - Hh \geq 0 \quad \text{on} \quad \mathbb{R}^+ , \\
  \liminf_{t \to 0} \left( \frac{h'}{h} - \frac{1}{t} \right) \geq 0 .
\end{cases} \tag{16}
\]

Let \(u : M \rightarrow \mathbb{R}\) solve (MSE). Then, denoting by \(\Delta_g\) the Laplacian in the graph metric \(g\),

\[ \Delta_g r \leq m \frac{h'(r)}{h(r)} \]

pointwise on \(M \setminus \{o\} \cup \text{cut}(o)\) and in the barrier sense on \(M \setminus \{o\}\).

**Proof.** Outside of \(\{o\} \cup \text{cut}(o)\), denote by \(\{\lambda_j(D^2r)\}\) the eigenvalues of \(D^2r\) in increasing order. The comparison theorem in [Mari and Pessoa 2020, Proposition 7.4] guarantees that

\[ \sum_{j=2}^{m} \lambda_j(D^2r) \leq (m - 1) \frac{h'(r)}{h(r)} \tag{17} \]

pointwise on \(M \setminus \{o\} \cup \text{cut}(o)\) and in the barrier sense on \(M \setminus \{o\}\). Note that the initial assumptions on \(h\) therein are \(h(0) = 0\), \(h'(0) \geq 1\), but the same proof works for the more general (16). In this respect, note that \(h' > 0\) on \(\mathbb{R}^+\) follows from \(H \geq 0\).

To estimate \(\Delta_g r = g^{ij}r_{ij}\), pick a point \(x\) where \(r\) is smooth. If \(Du(x) = 0\), then \(g^{ij} = \sigma^{ij}\). In our assumptions, the Ricci curvature satisfies

\[ \text{Ric}(\nabla r, \nabla r) \geq -(m - 1)H(r) , \]

so by the Laplacian comparison theorem and since \(h' > 0\),

\[ \Delta_g r = \text{Tr}(D^2r) \leq (m - 1) \frac{h'(r)}{h(r)} \leq m \frac{h'(r)}{h(r)} . \]

Assume that \(Du(x) \neq 0\), write \(v = Du/|Du|\) in a neighborhood of \(x\) and complete it to a local \(\sigma\)-orthonormal basis \(\{v, e_{\alpha}\}\) with \(2 \leq \alpha \leq m\). Note that \(g^{ij}\) is diagonalized with eigenvalues \(W^{-2} \leq 1\) in
direction $v$ and $1$ in directions $\{e_\alpha\}$. Expressing $\Delta_gr$ in the basis $\{e_\alpha, v\}$ we get

$$
\Delta_gr = \frac{1}{W^2} D^2 r(v, v) + \sum_{\alpha=2}^{m} D^2 r(e_\alpha, e_\alpha)
$$

$$
= \frac{1}{W^2} \left[ \text{Tr}(D^2 r) - \sum_{\alpha=2}^{m} D^2 r(e_\alpha, e_\alpha) \right] + \sum_{\alpha=2}^{m} D^2 r(e_\alpha, e_\alpha)
$$

$$
= \frac{1}{W^2} \text{Tr}(D^2 r) + \left[ \frac{W^2 - 1}{W^2} \right] \sum_{\alpha=2}^{m} D^2 r(e_\alpha, e_\alpha).
$$

(18)

By min-max and since the eigenvalues are ordered,

$$
\text{Tr}(D^2 r) \leq \frac{m}{m-1} \sum_{\alpha=2}^{m} \lambda_\alpha(D^2 r), \quad \sum_{\alpha=2}^{m} D^2 r(e_\alpha, e_\alpha) \leq \sum_{\alpha=2}^{m} \lambda_\alpha(D^2 r).
$$

Therefore,

$$
\Delta_gr \leq \left[ \frac{m}{(m-1)W^2} + \frac{W^2 - 1}{W^2} \right] \sum_{\alpha=2}^{m} \lambda_\alpha(D^2 r)
$$

$$
\leq \left[ \frac{1}{(m-1)W^2} + 1 \right] \frac{h'(r)}{h(r)} \leq m \frac{h'(r)}{h(r)}.
$$

(19)

as claimed. The validity of (17) in the barrier sense on the entire $M\setminus\{o\}$ easily follows by Calabi’s trick; see [Mari and Pessoa 2020, Proposition 7.4].

□

Remark 14. In particular, letting $\bar{\kappa} \in \mathbb{R}^+$, for $\ell = \max\{1, m-2\}$ it holds

$$
\text{Ric}^{(\ell)}(\nabla r) \geq -\bar{\kappa}^2 \quad \Rightarrow \quad \Delta_gr \leq m \bar{\kappa} \coth(\bar{\kappa} r),
$$

$$
\text{Ric}^{(\ell)}(\nabla r) \geq -\frac{\bar{\kappa}^2}{1+r^2} \quad \Rightarrow \quad \Delta_gr \leq \frac{m(1 + \sqrt{1+4\bar{\kappa}^2})}{2r}
$$

pointwise outside of $\{o\} \cup \text{cut}(o)$ and in the barrier sense on $M\setminus\{o\}$. Indeed, it is enough to consider for $h$, respectively, the functions

$$
h(t) = \frac{\sinh(\bar{\kappa} t)}{\bar{\kappa}} \quad \text{and} \quad h(t) = t^{\bar{\kappa}'} \quad \text{where} \quad \bar{\kappa}' = \frac{1 + \sqrt{1+4\bar{\kappa}^2}}{2}.
$$

3. Proof of Theorem 6(i)

Since $\text{Ric} \geq 0$ and $M$ is parabolic, by Remark 5 the manifold $(M, \sigma)$ satisfies

$$
\int_{|B_r|}^{\infty} \frac{s}{s} ds = \infty.
$$

(20)

We apply an argument outlined in [Colding and Minicozzi 2011, p. 48] for minimal graphs in $\mathbb{R}^3$. First, a calibration method in [Li and Wang 2001] (see also [Colding and Minicozzi 2011; Trudinger 1972] for the case $M = \mathbb{R}^m$) shows that the volume of the graph $\Sigma = (M, g)$ inside an extrinsic ball $B_r \subset \mathbb{R} \times M$
centered at a point \((u(o), o)\) satisfies
\[
|\Sigma \cap B_r| \leq |B_r| + \frac{1}{2} |B_{3r} \setminus B_r| \leq 2|B_{3r}|.
\]
Hence, the volume of a geodesic ball \(B_r^g\) in \(\Sigma\) centered at \(o\) is bounded by
\[
|B_r^g| \leq |\Sigma \cap B_r| \leq 2|B_{3r}|,
\]
which implies
\[
\int_{B_r^g} s \, ds = \infty.
\]
Therefore, by Remark 5, the graph \(\Sigma = (M, g)\) is parabolic. Because of the Jacobi equation
\[
\Delta_g \frac{1}{W} = -(\|II\|^2 + \overline{\text{Ric}}(n, n)) \frac{1}{W},
\]
the bounded function \(1/W\) is superharmonic on \(\Sigma\), and hence constant by parabolicity. Since \(\text{Ric} \geq 0\) implies \(\overline{\text{Ric}} \geq 0\), again from the Jacobi equation we deduce \(\text{II} \equiv 0\) and \(\Sigma\) is totally geodesic in \(M \times \mathbb{R}\). Equivalently, by (10), \(D^2u \equiv 0\) in \(M\). As a consequence, since \(u\) is nonconstant, \(Du\) is a nonzero parallel vector field. The flow of \(Du\) therefore splits \(M\) isometrically as a product \(N \times \mathbb{R}\), and \(u\) is an affine function of the \(\mathbb{R}\)-coordinate alone.

### 4. A local gradient estimate

Let \(u : B_R \subset M \to \mathbb{R}\) solve (MSE) on a geodesic ball \(B_R = B_R(x)\). The original argument in [Bombieri et al. 1969b] to prove the gradient estimate in Euclidean setting \((M = \mathbb{R}^m)\)
\[
|Du(x)| \leq c_1 \exp \left\{ c_2 \frac{u(x) - \inf_{B_R} u}{R} \right\}
\]
for some constants \(c_j = c_j(m)\) makes use of the isoperimetric inequality, which does not hold for minimal graphs over manifolds \((M, \sigma)\) with \(\text{Ric} \geq 0\) unless \(M\) has maximal volume growth compatible with the Bishop–Gromov inequality, in the sense that \((2, \alpha)\) is satisfied. Indeed, the isoperimetric inequality forces geodesic balls \(B_r^g\) in the graph \(\Sigma = (M, g)\) to satisfy \(|B_r^g| \geq Cr^m\), which coupled with (21) imply that \(M\) has Euclidean volume growth.

The exponential bound in (22) is sharp; see [Finn 1963]. On the other hand, in their seminal paper Bombieri and Giusti [1972] proved a different estimate for entire solutions: if \(u : \mathbb{R}^m \to \mathbb{R}\) solves (MSE), then for any \(x \in \mathbb{R}^m\) and \(R > 0\)
\[
|Du(x)| \leq c_1 \left\{ \frac{1 + \sup_{B_R} |u|}{R} \right\}^m,
\]
where \(c_1 = c_1(m)\). Whence, for entire solutions, an exponentially growing bound in terms of \(|u|\) is not sharp.

If \(M\) has \(\text{Ric} \geq 0\) and Euclidean volume growth, the validity of an isoperimetric inequality on entire minimal graphs was recently shown in [Ding 2021b]; see also [Brendle 2023] for the case \(\text{Sec} \geq 0\). As a consequence, in [Ding 2021b, Theorems 1.3 and 6.2] the author was able to extend (22) and (23) to such manifolds.
An alternative method to prove (22) in Euclidean setting was given by N. Trudinger [1972]. His strategy hinges on a mean value inequality on \( \Sigma \) which, remarkably, is obtained without needing the isoperimetric inequality and is therefore suited to apply to manifolds whose volume growth is not Euclidean. However, to adapt the proof to minimal graphs over \( M \), it seems that an upper bound on the sectional curvature of \( M \) is necessary; see also the related [Ding et al. 2016]. Later, N. Korevaar [1986] gave new insight into the problem, finding a striking argument to get gradient estimates that only requires lower bounds on the curvatures of \( M \). Exploiting Korevaar’s method, in [Rosenberg et al. 2013] the authors obtained the slightly different estimate

\[
|Du(x)| \leq c_1 \exp \left\{ c_2 \left[ 1 + \bar{\kappa} R \coth(\bar{\kappa} R) \right] \frac{(u(x) - \inf_{B_R} u)^2}{R^2} \right\},
\]

provided that \( \text{Ric} \geq 0 \) and \( \text{Sec} \geq -\bar{\kappa}^2 \). Note that, unless \( \bar{\kappa} = 0 \), the estimate explodes as \( R \to \infty \) if \( u : M \to \mathbb{R} \) is of linear growth. Extensions to more general ambient spaces were later given in [Casteras et al. 2020; Dajczer and de Lira 2015; 2017], but they only consider graphs which are bounded on one side or have logarithmic growth.

Inspecting the proofs in [Rosenberg et al. 2013; Dajczer and de Lira 2015; 2017; Ding et al. 2016], to reach the inequality \( |Du(x)| \leq C \) for solutions of linear growth, with \( C \) uniform with respect to \( x \), the bounds on Sec are instrumental to guarantee that the distance \( r_x \) from \( x \) satisfies \( \Delta_g r_x \leq C_1/r_x \) for some absolute constant \( C_1 \). In view of the arbitrariness of the point \( x \), assumption Sec \( \geq 0 \) in [Rosenberg et al. 2013] seems therefore difficult to replace by a weaker control on Sec from below. For instance, if one considers the inequality \( \text{Sec} \geq -\bar{\kappa}^2/(1 + r_o^2) \) for some constant \( \bar{\kappa} > 0 \) and some origin \( o \), comparison theory and standard estimates for ODE would yield to a constant \( C_1 \), hence \( C \), that depends on the distance of \( x \) from \( o \) and explodes as \( r_o(x) \to \infty \), making the estimate on \( \Delta_g r_x \) insufficient to imply the desired uniform gradient bound.

From a different perspective, we mention that a global gradient estimate for positive entire solutions was obtained in [Colombo et al. 2022] under the sole curvature assumption

\[
\text{Ric} \geq -(m - 1)\kappa^2, \quad \kappa \in \mathbb{R}^+_0,
\]

namely, a positive solution to (MSE) on the entire \( M \) shall satisfy

\[
\sqrt{1 + |Du(x)|^2} \leq e^{\kappa u(x)\sqrt{m-1}} \quad \text{for all } x \in M.
\]

Note that (\( \mathcal{R}2 \)) directly follows if \( \kappa = 0 \). However, modifying the argument in [Colombo et al. 2022] to allow for linearly growing solutions seems challenging.

Our first main result, Theorem 15, provides an improvement of Korevaar’s method that apply to the more general assumption (8).

**Theorem 15.** Let \( (M, \sigma) \) be a complete Riemannian manifold with dimension \( m \geq 2 \). Let \( B_R = B_R(o) \subset M \) be a geodesic open ball of radius \( R > 0 \) centered at \( o \in M \) and let \( u \in C^3(B_R) \) be a nonconstant solution to (MSE). Assume that

\[
\text{Ric} \geq -(m - 1)\kappa^2, \quad \text{Ric}(\nabla r) \geq -\frac{\bar{\kappa}^2}{1 + r^2} \quad \text{on } B_R, \quad \ell = \max\{1, m - 2\},
\]
for some $\kappa, \bar{\kappa} \in \mathbb{R}_0^+$, where $r$ denotes the distance from $o$. Let $0 < R_1 < R$. Then,

$$\sqrt{1 + |Du(x)|^2} \leq \max\left\{ \sqrt{1 + a_0^2(y^*)^2}, \sqrt{\frac{a_3}{a_3 - a_2}} \right\} \left( \frac{e^{LR(\sqrt{\varepsilon^2 + 1} - \varepsilon)} - 1}{e^{LR(\sqrt{\varepsilon^2 + 1} - \varepsilon(\varepsilon(x)^2/R^2 - qy(x)))} - 1} \right)$$

for every $x \in B_{R_1}(o)$, where

$$\gamma(x) = \frac{u(x) - \inf_{B_R} u}{R}, \quad \gamma^* = \sup_{x \in B_{R_1}} \gamma(x) = \frac{\sup_{B_{R_1}} u - \inf_{B_R} u}{R},$$

$\varepsilon > 0$ and $\tau \in (0, 1)$ are fixed arbitrarily, $q, a_0 \in \mathbb{R}^+$ satisfy

$$\frac{\sqrt{1 + \varepsilon^2 - \sqrt{(R_1/R)^2 + \varepsilon^2}}}{\gamma^*} > q > \frac{1}{\sqrt{\tau a_0} \gamma^*} > 0$$

and $L \in \mathbb{R}^+$ satisfies

$$(1 - \tau) \left( q^2 - \frac{1}{\tau a_0^2 (\gamma^*)^2} \right) L^2 - \frac{(m + 1) \bar{\kappa}_0 L}{\varepsilon R} > (m - 1) \kappa^2,$$

with $\bar{\kappa}_0 = \max\{1, \bar{\kappa}\}$. Finally, $a_2, a_3$ are defined by

$$a_2 = \frac{(m + 1) \bar{\kappa}_0 L}{\varepsilon R}, \quad a_3 = (1 - \tau) \left( q^2 - \frac{1}{\tau a_0^2 (\gamma^*)^2} \right) L^2 - (m - 1) \kappa^2.$$

**Remark 16.** The assumption that $u$ is nonconstant ensures that $\gamma^* > 0$ by the maximum principle.

Before proving the theorem, we give some applications, starting from the case where $\kappa = 0$.

**Corollary 17.** Let $(M^m, \sigma)$ be a complete Riemannian manifold with $\text{Ric} \geq 0$ and

$$\text{Ric}^{(\ell)}(\nabla r) \geq -\frac{\bar{\kappa}^2}{1 + r^2}, \quad \ell = \max\{1, m - 2\},$$

for some $\bar{\kappa} \in \mathbb{R}_0^+$, where $r$ denotes the distance from $o$. Let $u \in C^3(\overline{B}_R)$ solve (MSE). Then, for every $\delta \in (0, 1)$ and for every $R_1 \in (0, \delta R)$,

$$\sup_{B_{R_1}} \sqrt{1 + |Du|^2} \leq C_1 \exp\left( C_2 m \bar{\kappa}_0 \frac{\sup_{B_{R_1}} u - \inf_{B_R} u}{R^2} \right),$$

with $\bar{\kappa}_0 = \max\{1, \bar{\kappa}\}$ and $C_1, C_2 > 0$ only depending on $\delta$.

**Proof.** The desired inequality is trivial if $u$ is constant, so assume that $u$ is nonconstant. It suffices to prove the claim for $\delta \in \left[\frac{1}{2}, 1\right)$. Let

$$\gamma^* = \frac{\sup_{B_{R_1}} u - \inf_{B_R} u}{R}.$$

Choose

$$\tau = \frac{1}{2}, \quad \varepsilon = \delta, \quad q = \frac{1 - \delta}{2\sqrt{2}\gamma^*}, \quad a_0 = \frac{2}{q\gamma^*}, \quad L = \frac{8(m + 1) \bar{\kappa}_0}{\delta Rq^2}.$$
With this choice, we have
\[ \frac{\sqrt{1 + \varepsilon^2} - \sqrt{(R_1/R)^2 + \varepsilon^2}}{\gamma^*} \geq \frac{\sqrt{1 + \varepsilon^2} - \sqrt{\delta^2 + \varepsilon^2}}{\gamma^*} = \frac{\sqrt{1 + \delta^2} - \sqrt{2\delta}}{\gamma^*} \geq 2q, \] (26)
where, from $\delta < 1$, we used
\[ \sqrt{1 + \delta^2} - \sqrt{2\delta} = \frac{1 - \delta^2}{\sqrt{1 + \delta^2 + \sqrt{2}\delta}} \geq \frac{1 - \delta^2}{\sqrt{2 + \sqrt{2}\delta}} = \frac{1 - \delta}{\sqrt{2}}. \]

We also have
\[ q^2 - \frac{1}{a^2_0(\gamma^*)^2\tau} = q^2 - \frac{q^2}{2} = \frac{q^2}{2} \]
and then
\[ a_3 = (1 - \tau)\left(q^2 - \frac{1}{a^2_0(\gamma^*)^2\tau}\right) L^2 = \frac{L^2 q^2}{4} = 2\frac{(m + 1)\bar{\kappa}_0L}{\varepsilon R} = 2a_2. \]

Hence, all assumptions of Theorem 15 are satisfied and for every $x \in B_{R_1}$ we have
\[ \sqrt{1 + |Du(x)|^2} \leq \max\left\{ \sqrt{1 + a^2_0(\gamma^*)^2}, \sqrt{2} \right\} \cdot \frac{e^{LR(\sqrt{1 + \varepsilon^2} - \varepsilon)} - 1}{e^{LR(\sqrt{1 + \varepsilon^2} - \sqrt{(r(x)/R)^2 + \varepsilon^2 - q\gamma(x)})} - 1}. \]

Note that, for every $x \in B_{R_1}$ and taking into account (26),
\[ \sqrt{1 + \varepsilon^2} - \sqrt{(r(x)/R)^2 + \varepsilon^2 - q\gamma(x)} \geq \sqrt{1 + \varepsilon^2} - \sqrt{\delta^2 + \varepsilon^2 - q\gamma^*} \geq 2q\gamma^* - q\gamma^* = q\gamma^*, \]
and also
\[ \sqrt{1 + \varepsilon^2} - \varepsilon = \frac{1}{\sqrt{1 + \varepsilon^2 + \varepsilon}} \leq \frac{1}{\sqrt{1 + \varepsilon^2}} = \frac{1}{\sqrt{1 + \delta^2}} \leq \frac{1}{\sqrt{2\delta}} = \frac{2}{\delta(1 - \delta)q\gamma^*}. \]

Therefore, we can estimate
\[ \frac{e^{LR(\sqrt{1 + \varepsilon^2} - \varepsilon)} - 1}{e^{LR(\sqrt{1 + \varepsilon^2} - \sqrt{(r(x)/R)^2 + \varepsilon^2 - q\gamma(x)})} - 1} \leq \frac{e^{LR(\frac{2}{\delta(1 - \delta)q\gamma^*})} - 1}{e^{LRq\gamma^*} - 1} \leq C(\delta)e^{LR(\frac{2}{\delta(1 - \delta)q\gamma^*})}. \]

Here, we have exploited the fact that for every $\alpha \in \mathbb{R}$ one has the validity of an inequality of the form
\[ \frac{y^\alpha - 1}{y - 1} \leq C(\alpha)y^{\alpha-1} \quad \text{for all } y > 1 \]
for a suitable constant $C(\alpha) > 0$. Recalling that
\[ a^2_0(\gamma^*)^2 = \frac{32(\gamma^*)^2}{(1 - \delta)^2}, \quad LRq\gamma^* = \frac{8(m + 1)\bar{\kappa}_0\gamma^*}{\delta q} = \frac{16\sqrt{2}(m + 1)\bar{\kappa}_0}{\delta(1 - \delta)}(\gamma^*)^2, \]
we obtain
\[ \sqrt{1 + |Du(x)|^2} \leq \max\left\{ \sqrt{1 + \frac{32(\gamma^*)^2}{(1 - \delta)^2} \cdot \sqrt{2}} \right\} \cdot C(\delta) \exp\left( \frac{16\sqrt{2}(m + 1)\bar{\kappa}_0}{\delta(1 - \delta)} \left( \frac{2}{\delta(1 - \delta)} - 1 \right) (\gamma^*)^2 \right) \]
and the conclusion follows. \[ \square \]
Assuming that $u$ has at most linear growth, we get:

**Corollary 18.** Let $(M^m, \sigma)$ be a connected, complete Riemannian manifold with $\text{Ric} \geq 0$ and

$$\text{Ric}(\ell)(\nabla r) \geq -\frac{\bar{\kappa}^2}{1+r^2}, \quad \ell = \max\{1, m - 2\},$$

for some $\bar{\kappa} \in \mathbb{R}^+_0$. If $u \in C^\infty(M)$ solves (MSE) and has at most linear growth on one side, then $|Du| \in L^\infty(M)$.

**Proof.** Without loss of generality we can assume that the negative part of $u$ has at most linear growth, so that there exists $a > 0$ such that $u(x) \geq -a(1 + r(x))$ for every $x \in M$. Let $R_1 > 0$ be fixed. Choosing $\delta = \frac{1}{2}$ and letting $R \to \infty$ in estimate (25) we get

$$\sup_{B_{R_1}} \sqrt{1 + |Du|^2} \leq C_1 \exp(C_2 m \bar{\kappa} a^2),$$

where $C_1, C_2 > 0$ do not depend on $R_1$. Since $R_1 > 0$ was arbitrary, the conclusion follows. \qed

To prove Theorem 15, we need the following:

**Lemma 19.** Let $(M^m, \sigma)$ be a complete Riemannian manifold with

$$\text{Ric}(\ell)(\nabla r) \geq -\frac{\bar{\kappa}^2}{1+r^2}, \quad \ell = \max\{1, m - 2\},$$

for some $\bar{\kappa} \in \mathbb{R}^+_0$, where $r$ is the distance from a fixed origin $o \in M$, and let $u \in C^\infty(B_R)$ solve (MSE) on a geodesic ball $B_R$ centered at $o$.

For any given $a > 0$, the function $\psi = \sqrt{a^2 + r^2}$ satisfies

$$|D\psi| < 1, \quad \Delta_g \psi \leq (m + 1) \frac{\max\{1, \bar{\kappa}\}}{a}$$

in the barrier sense on $B_R$ and pointwise on $B_R \setminus \text{cut}(o)$.

**Remark 20.** By its very definition, a solution in the barrier sense is also a solution in the viscosity sense; see [Mantegazza et al. 2014] for comments.

**Proof.** Outside of $\{o\} \cup \text{cut}(o)$, a direct computation yields $|D\psi| = (r/\psi)|Dr| < 1$ and

$$\Delta_g \psi = \frac{r \Delta_g r}{\sqrt{a^2 + r^2}} + \frac{a^2 \|\nabla r\|^2}{(a^2 + r^2)^{3/2}}.$$ 

From $\|\nabla r\|^2 = g^{ij} r_i r_j \leq |Dr|^2 = 1$ and Remark 14,

$$\Delta_g \psi \leq \frac{1}{\sqrt{a^2 + r^2}} \left( \frac{m(1 + \sqrt{1 + 4\bar{\kappa}^2})}{2} + \frac{a^2}{a^2 + r^2} \right)$$

and the conclusion follows by observing that $1/\sqrt{a^2 + r^2} \leq 1/a$ and that

$$\frac{m(1 + \sqrt{1 + 4\bar{\kappa}^2})}{2} + \frac{a^2}{a^2 + r^2} \leq m(1 + \bar{\kappa}) + 1 \leq (m + 1) \max\{1, \bar{\kappa}\}.$$
The validity of the inequality in the barrier sense can be proved by Calabi’s trick; see for instance [Mari and Pessoa 2020, Proposition 7.4]. □

Proof of Theorem 15. Without loss of generality, we can assume \( \inf_{B_R} u = 0 \). Then

\[
\gamma^* = \sup_{x \in B_{R_1}} \gamma(x) = \frac{\sup_{B_{R_1}} u}{R}.
\]

As in the statement of the theorem, fix \( \tau \in (0, 1) \) and \( \epsilon > 0 \), choose \( q > 0 \) and \( a_0 > 0 \) such that

\[
\sqrt{\frac{\epsilon^2 + 1 - \sqrt{(R_1/R)^2 + \epsilon^2}}{\gamma^*}} > q > \frac{1}{\sqrt{\tau a_0 \gamma^*}} \tag{27}
\]

and then \( L > 0 \), which satisfies

\[
(1 - \tau) \left( q^2 - \frac{1}{\tau a_0^2 (\gamma^*)^2} \right) L^2 - \frac{(m + 1) \tilde{k}_0 L}{\epsilon R} > (m - 1) \kappa^2, \tag{28}
\]

where \( \tilde{k}_0 = \max\{1, \bar{k}\} \). Set

\[
C = qL, \quad \delta = e^{-LR\sqrt{\epsilon^2 + 1}},
\]

define the function

\[
\psi = \sqrt{\epsilon^2 R^2 + r^2},
\]

where \( r(x) = \text{dist}_\sigma(o, x) \), and let

\[
\eta = e^{-Cu - L\psi} - \delta, \quad z = W\eta.
\]

By writing

\[
\eta = \delta(e^{LR(\sqrt{\epsilon^2 + 1} - \sqrt{r^2 + (R/\gamma^*)^2 - qu/R})} - 1),
\]

we see that for every \( x \in B_{R_1} \)

\[
\eta(x) \geq \delta(e^{LR(\sqrt{\epsilon^2 + 1} - \sqrt{r^2 + r(x)^2/R^2 - qu/R})} - 1) \geq \delta(e^{LR(\sqrt{1 + \epsilon^2} - \sqrt{(R_1/R)^2 + \epsilon^2 - qu/R})} - 1) > 0
\]

as a consequence of (27). Noting that, on \( \partial B_R \),

\[
\eta = \delta(e^{-q Lu} - 1) \leq 0,
\]

the set

\[
\Omega = \{ x \in B_R : z(x) > 0 \} \equiv \{ x \in B_R : \eta(x) > 0 \}
\]

is nonempty and satisfies \( B_{R_1} \subseteq \Omega \subseteq \overline{B_R} \). Therefore, there exists \( x_0 \in \Omega \) such that

\[
0 < z(x_0) = \max_\Omega z.
\]

The function \( z \) satisfies

\[
\Delta_g z - 2\langle \nabla z, \nabla \log W \rangle = \left( - (m - 1) \kappa^2 \| \nabla u \|^2 + \frac{\Delta_g \eta}{\eta} \right) z \quad \text{on} \ \Omega.
\]
The above inequality has to be interpreted in the viscosity sense, in case \( x_0 \) is not a point where \( r \) (hence \( \psi \)) is smooth. By the maximum principle, necessarily

\[
-(m - 1)\kappa^2 \| \nabla u \|^2 + \frac{\Delta_g \eta}{\eta} \leq 0 \quad \text{at } x_0
\]

(29)
in the viscosity sense. We compute

\[
\Delta_g \eta = (\eta + \delta)(-C \Delta_g u - L \Delta_g \psi + \| \nabla u + L \nabla \psi \|^2).
\]

We recall that \( W^{-2}(\sigma^{ij})_{i,j} \leq (g^{ij})_{i,j} \leq (\sigma^{ij})_{i,j} \) in the sense of quadratic forms; hence

\[
\| \nabla u + L \nabla \psi \|^2 = g^{ij}(Cu_i + L \psi_i)(Cu_j + L \psi_j) \geq \frac{1}{W^2} \sigma^{ij}(Cu_i + L \psi_i)(Cu_j + L \psi_j) \geq \frac{1}{W^2} |CDu + LD\psi|^2.
\]

It follows that

\[
\frac{\Delta_g \eta}{\eta + \delta} \geq -C \Delta_g u - L \Delta_g \psi + \frac{1}{W^2} |CDu + LD\psi|^2.
\]

Using \( \Delta_g u = 0 \) and Young’s inequality we obtain

\[
\frac{\Delta_g \eta}{\eta + \delta} \geq -L \Delta_g \psi + (1 - \tau)C^2 \frac{|Du|^2}{W^2} - L^2 \frac{1 - \tau}{\tau} \frac{|D\psi|^2}{W^2}.
\]

Taking into account Lemma 19 we infer

\[
|D\psi| < 1, \quad \Delta_g \psi \leq \frac{(m + 1)\bar{\kappa}_0}{\bar{\epsilon} R}.
\]

Substituting these estimates in the above inequality, we deduce

\[
\frac{\Delta_g \eta}{\eta + \delta} \geq (1 - \tau)C^2 \frac{|Du|^2}{W^2} - L \left( \frac{(m + 1)\bar{\kappa}_0}{\bar{\epsilon} R} + \frac{1 - \tau}{\tau} \frac{L}{W^2} \right).
\]

If \( |Du(x_0)| \geq a_0 \gamma^* \) then

\[
\frac{|Du(x_0)|^2}{W^2 a_0^2(\gamma^*)^2} \geq \frac{1}{W^2}.
\]

Thus, we can further estimate

\[
\frac{\Delta_g \eta}{\eta + \delta} \geq (1 - \tau)\left( q^2 - \frac{1}{\tau a_0^2(\gamma^*)^2} \right) L^2 \frac{|Du|^2}{W^2} - \frac{(m + 1)\bar{\kappa}_0 L}{\bar{\epsilon} R} \quad \text{at } x_0,
\]

that is,

\[
\frac{\Delta_g \eta}{\eta + \delta} \geq a_1 \| \nabla u \|^2 - a_2,
\]

(30)

with

\[
a_1 = (1 - \tau)\left( q^2 - \frac{1}{\tau a_0^2(\gamma^*)^2} \right) L^2 > 0, \quad a_2 = \frac{(m + 1)\bar{\kappa}_0 L}{\bar{\epsilon} R} > 0.
\]
Since
\[ a_3 = a_1 - (m - 1)\kappa^2, \]
we have \( a_1 \geq a_3 > 0 \) by condition (28). We claim that
\[ \frac{|Du(x_0)|^2}{W^2(x_0)} = \|u(x_0)\|^2 \leq \frac{a_2}{a_3}, \]
that is,
\[ W(x_0) \leq \sqrt{\frac{a_3}{a_3 - a_2}}. \quad (31) \]
Indeed, assume by contradiction that
\[ \|\nabla u(x_0)\|^2 > \frac{a_2}{a_3}. \quad (32) \]
Then, from (30) it follows
\[ \frac{\Delta \eta}{\eta + \delta} \geq a_3\|\nabla u\|^2 - a_2 > 0 \quad \text{at } x_0; \]
hence \( \Delta \eta > 0 \) and, by (29) and (30) again,
\[ (m - 1)\kappa^2\|\nabla u\|^2 \geq \frac{\Delta \eta}{\eta + \delta} \geq a_1\|\nabla u\|^2 - a_2 \quad \text{at } x_0, \]
leading to
\[ a_2 \geq (a_1 - (m - 1)\kappa^2)\|\nabla u\|^2 = a_3\|\nabla u\|^2 \quad \text{at } x_0, \]
which contradicts (32) and proves our claim.

On the other hand, if \( |Du(x_0)| \leq a_0\gamma^s \), then
\[ W(x_0) \leq \sqrt{1 + a_0^2\gamma^2}. \quad (33) \]
Since \( x_0 \) is a global maximum point for \( z \) in \( \Omega \), we have \( z(x) \leq z(x_0) \), that is,
\[ W(x) \leq W(x_0) \frac{\eta(x_0)}{\eta(x)} \]
for every \( x \in B_{R_1} \subseteq \Omega \). Note that
\[ \frac{\eta(x_0)}{\eta(x)} = \frac{e^{LR(\sqrt{\varepsilon^2+u(x)}/R) - 1 - qu(x)/R}}{e^{LR(\sqrt{\varepsilon^2+u(x)}/R) - 1} - 1} \leq \frac{e^{LR(\sqrt{\varepsilon^2+u(x)}/R) - 1 - qu(x)/R}}{e^{LR(\sqrt{\varepsilon^2+u(x)}/R) - 1} - 1}; \]
hence
\[ W(x) \leq W(x_0)\left(\frac{e^{LR(\sqrt{\varepsilon^2+1-\varepsilon} - 1)} - 1}{e^{LR(\sqrt{\varepsilon^2+1-\varepsilon} - 1) - 1} - 1}\right). \]
The latter, together with (31) and (33), implies the desired estimate. \(\square\)
5. Uniformly elliptic operators on manifolds with $\text{Ric} \geq 0$

Having shown that an entire minimal graph with at most linear growth on one side has globally bounded gradient, we need to show (6) and (7). We shall prove both of them under the only conditions

$$ \text{Ric} \geq 0, \quad |Du| \in L^\infty(M). \quad (34) $$

In such generality, it seems difficult to apply the “elliptic” approach in [Cheeger et al. 1995], adapted in [Ding et al. 2016; Ding 2021b]. To justify the statement, we observe that the method in [Cheeger et al. 1995] relies on the construction of a function $\varrho$ satisfying

$$ C^{-1}r \leq \varrho \leq Cr, \quad |D\varrho| \leq C, \quad \Delta_g \varrho \leq \frac{C}{\varrho} \quad (35) $$

for some absolute constant $C$. When considering harmonic functions, the third condition is replaced by $\Delta \varrho \leq C/\varrho$; thus by comparison theory the choice $\varrho = r$ is admissible. On the contrary, to our knowledge, for minimal graphs the existence of $\varrho$ satisfying (35) is currently unknown under the sole assumptions (34).

If $M$ has Euclidean volume growth, we mention that in [Ding et al. 2016; Ding 2021b] the authors used as $\varrho$ a reparametrization of the Green kernel of the Laplacian on $M$. Although the inequality $\Delta_g \varrho \leq C/\varrho$ may not hold pointwise, the integral estimates for $|D^2\varrho|$ provided in [Colding and Minicozzi 1997] suffice to estimate $\Delta_g \varrho$ and apply the method in [Cheeger et al. 1995], as done in [Ding 2021b, Lemma 7.1]. However, to our knowledge, estimates like those in [Colding and Minicozzi 1997] are not yet (if ever) available on manifolds with $\text{Ric} \geq 0$ but whose volume growth is less than Euclidean.

For these reasons, inspired by [Li 1986; Saloff-Coste 1992] we choose a different approach via the heat equation. Throughout this section, let $(M, \sigma)$ be a connected, complete Riemannian manifold of dimension $m \geq 2$ with $\text{Ric} \geq 0$. Let $L$ be the linear uniformly elliptic operator defined by

$$ L\psi = \text{div}(AD\psi), \quad (36) $$

where $A$ is a measurable section of $T^{1,1}M$ satisfying

$$ \alpha^{-1}|X|^2 \leq \langle AX, X \rangle \quad \text{and} \quad |AX| \leq \alpha|X| \quad \text{for all} \quad X \in TM, \quad (37) $$

for some constant $\alpha > 0$. Hereafter, we shall assume that $A$ is smooth, the general case being obtainable by approximation.

We denote by $H_L(x, y, t)$ the minimal heat kernel associated to the parabolic operator $\partial_t - L$, that is, the unique continuous function on $M \times M \times \mathbb{R}^+$ such that for every $\psi \in C_0^\infty(M)$ the function $u$ defined by

$$ u(t, x) = \int_M H_L(x, y, t)\psi(y)\,dy \quad \text{for all} \quad (t, x) \in \mathbb{R}^+ \times M $$

is a solution to

$$ \partial_t u = Lu \quad (38) $$

on $\mathbb{R}^+ \times M$ satisfying

(i) $u(t, \cdot) \to \psi$ pointwise on $M$ as $t \searrow 0$, 

(ii) \( u \leq v \) on \((0, T) \times M\) for every \( v \in C^2((0, T) \times M) \), \( T > 0 \), such that
\[
\begin{cases}
\partial_t u = Lv & \text{on } (0, T) \times M, \\
\psi \leq v(0, \cdot) & \text{on } M.
\end{cases}
\]

If the endomorphism \( A \) is self-adjoint with respect to \( \langle \cdot, \cdot \rangle \), the minimal heat kernel \( H_L \) is a symmetric function of the space variables, that is,
\[
H_L(x, y, t) = H_L(y, x, t) \quad \text{for all } x, y \in M, \text{ for all } t > 0.
\] (39)

By [Saloff-Coste 1992], see Corollary 6.2 and Theorem 6.3, there exist positive constants \( C_i > 0 \), \( 1 \leq i \leq 6 \), depending only on \( m \) and \( \alpha \) such that, for every \( x, y \in M \) and \( t > 0 \),
\[
C_1 \frac{\exp(-C_2 \operatorname{dist}(x, y)^2/t)}{\sqrt{\|B_{\sqrt{t}}(x)\|\|B_{\sqrt{t}}(y)\|}} \leq H_L(x, y, t) \leq C_3 \frac{\exp(-C_4 \operatorname{dist}(x, y)^2/t)}{\sqrt{\|B_{\sqrt{t}}(x)\|\|B_{\sqrt{t}}(y)\|}}
\] (40)
and
\[
|\partial_t H_L(x, y, t)| \leq \frac{C_5 \exp(-C_6 \operatorname{dist}(x, y)^2/t)}{t \sqrt{\|B_{\sqrt{t}}(x)\|\|B_{\sqrt{t}}(y)\|}}.
\] (41)

Remarks on (40) will be given in the Appendix. We first need the following simple estimate on the volume of geodesic balls.

**Lemma 21.** Let \((M^m, \sigma)\) be a complete manifold with \( \operatorname{Ric} \geq 0 \). For every \( x, y \in M \) and for every \( R > 0 \) it holds
\[
|B_R(x)| \left(1 + \frac{\operatorname{dist}(x, y)}{R}\right)^{-\frac{m}{2}} \leq \sqrt{|B_R(x)||B_R(y)|} \leq |B_R(x)| \left(1 + \frac{\operatorname{dist}(x, y)}{R}\right)^{\frac{m}{2}}.
\]

**Proof.** By the Bishop–Gromov comparison theorem we have
\[
\frac{|B_R(x)|}{|B_r(x)|} \leq \left(\frac{R}{r}\right)^m, \quad 0 < r \leq R < \infty;
\]
thus
\[
|B_R(y)| \leq |B_{R+\operatorname{dist}(x,y)}(x)| \leq |B_R(x)| \left(1 + \frac{\operatorname{dist}(x, y)}{R}\right)^{m},
\]
and the thesis follows. \( \square \)

Next, we recall that \( L \) generates a diffusion which is stochastically complete (see [Grigoryan 1999]), that is, the following holds:

**Lemma 22.** Let \( M \) be a complete manifold with \( \operatorname{Ric} \geq 0 \), and let \( A, L \) be as in (36)–(37), with \( A \) self-adjoint and smooth. Then
\[
\int_M H_L(x, y, t) \, dy = 1 \quad \text{for all } (t, x) \in \mathbb{R}^+ \times M.
\]

The result is stated with no proof in the discussion following [Saloff-Coste 1992, Theorem 7.4]. We here provide an argument for the convenience of the reader.

**Proof.** Since $L$ is uniformly elliptic and $M$ has polynomial volume growth as a consequence of $\text{Ric} \geq 0$, by Theorem 4.1 of [Alías et al. 2016] we have that for any $\lambda > 0$ the only entire bounded solution $v$ of $Lv = \lambda v$ on $M$ is $v \equiv 0$. Then the conclusion follows by [Pigola et al. 2005, Theorem 3.11]. \hfill \Box

With the above preparation, we are ready to state the following asymptotic mean value theorem. Our method is inspired by the one in [Li 1986], where the author considered the case $L = \Delta$, but with a difference to be stressed. Indeed, in that work the author uses the Li–Yau differential Harnack inequality to get rid of a boundary term at infinity. The inequality holds for solutions of the heat equation, but in general it may fail for solutions of $\partial_t u = Lu$, unless one has a uniform control on the gradient of $A$ on the entire $M$; see for instance [Saloff-Coste 1992, p. 433]. As we will apply our results to $A = W\text{Id} - W^{-1} du \otimes Du$, with $W = \sqrt{1 + |Du|^2}$, in our setting only an $L^\infty$ control on $A$ is available. One may therefore use De Giorgi-Nash-Moser theory to get Hölder estimates in space for $u$, see [Saloff-Coste 1992, Corollary 5.5], but these seem insufficient to treat the boundary term.

In view of the above, we shall modify the method in [Li 1986]. The main idea here is the use of upper level sets of $H_L$ rather than geodesic balls. Note that we do not assume a Euclidean volume growth. We start with the following:

**Lemma 23.** Let $(M^m, (\cdot, \cdot))$ be a connected, complete, noncompact manifold with $\text{Ric} \geq 0$ and let $A, L$ be as in (36)–(37), with $A$ self-adjoint and smooth. If $f \in C^2(M) \cap L^\infty(M)$ satisfies $Lf \leq 0$ on $M$ then the function $u : \mathbb{R}^+ \times M \to \mathbb{R}$ given by

$$u(t, x) = \int_M f(y) H_L(x, y, t) \, dy \quad \text{for all } (t, x) \in \mathbb{R}^+ \times M$$

satisfies

$$\partial_t u \leq 0 \quad \text{on } \mathbb{R}^+ \times M.$$  

**Proof.** Note that the integral on the right-hand side of (42) converges for every $(t, x) \in \mathbb{R}^+ \times M$ since $f \in L^\infty(M)$ and because of (40) and Lemma 21. Also note that $H_L$ is smooth as a consequence of the regularity assumptions on $A$. By Lemma 22, $u$ only varies by an additive constant if so does $f$; hence without loss of generality we can assume $\inf_M f = 0$. Let $(t, x) \in \mathbb{R}^+ \times M$ be fixed. For notational convenience, for every $a > 0$ we define

$$\varphi_a(y) = H_L(x, y, t) - a \quad \text{for all } y \in M, \quad \Omega_a = \{ y \in M : \varphi_a(y) > 0 \}.$$  

(44)

Because of (40) it holds $H_L(x, y, t) \to 0$ as $y \to \infty$ in $M$; hence the collection $\{ \Omega_a \}_{a > 0}$ is an exhaustion of $M$ by relatively compact open subsets, with $\Omega_a \subseteq \Omega_b$ when $a \geq b$. By (41) and boundedness of $f$, we can apply Lebesgue’s dominated convergence theorem to get

$$\partial_t u(t, x) = \int_M f(y) \partial_t H_L(x, y, t) \, dy = \lim_{a \to 0^+} \int_{\Omega_a} f(y) \partial_t H_L(x, y, t) \, dy.$$  

(45)

Therefore, since $Lf \leq 0$ and $\varphi_a > 0$ on $\Omega_a$, (43) holds by monotone convergence if we prove the inequality

$$\int_{\Omega_a} f(y) \partial_t H_L(x, y, t) \, dy \leq \int_{\Omega_a} \varphi_a(y) Lf(y) \, dy.$$  

(46)
Because of \( \partial_t H_L(x, y, t) = L_y H_L(x, y, t) = L \varphi(y) = L \varphi_a(y) \), we have

\[
\int_{\Omega_a} f(y) \partial_t H_L(x, y, t) \, dy = \int_{\Omega_a} f(y) L_y H_L(x, y, t) \, dy = \int_{\Omega_a} f(y) L \varphi_a(y) \, dy.
\]

Since \( H_L \in C^\infty(\mathbb{R}^+ \times M) \), we have \( \varphi \in C^\infty(M) \) and for almost every \( a > 0 \) the set \( \Omega_a \) has smooth boundary. Let \( a > 0 \) be a regular value for \( \varphi_a \). By Green’s identity, since \( \varphi_a = 0 \) on \( \partial \Omega_a \)

\[
\int_{\Omega_a} f(y) L \varphi_a(t, y) \, dy = \int_{\partial \Omega_a} \varphi_a(t, y) L f(y) \, dy + \int_{\partial \Omega_a} f(y) (AD \varphi_a(y), v) \, d\mathcal{H}^{m-1}(y),
\]

where \( v = -D \varphi_a/|D \varphi_a| \) is the outward-pointing normal on \( \partial \Omega_a \). Noting that \( f \geq 0 \), that \( \varphi_a \) is nonincreasing in the direction of \( v \) and that \( A \) is positive definite, we see that \( f (AD \varphi_a, v) \leq 0 \) on \( \partial \Omega_a \) and therefore the second integral is nonpositive, which implies the desired inequality (46). 

\( \square \)

**Proposition 24.** Let \((M^m, (\cdot, \cdot))\) be a connected, complete, noncompact manifold with \( \text{Ric} \geq 0 \) and let \( A, L \) be as in (36)–(37), with \( A \) self-adjoint and smooth. If \( f \in C^2(M) \cap L^\infty(M) \) satisfies \( Lf \leq 0 \) on \( M \), then for any \( x \in M \)

\[
\lim_{R \to \infty} \frac{1}{|B_R(x)|} \int_{B_R(x)} f(y) \, dy = \inf_M f. \tag{47}
\]

**Proof.** Without loss of generality, we assume \( \inf_M f = 0 \). Let \( u : \mathbb{R}^+ \times M \to \mathbb{R} \) be the function defined by (42). Note that \( u \) is the minimal solution to the parabolic equation \( \partial_t u = Lu \) on \( \mathbb{R}^+ \times M \) corresponding to the initial datum \( u(0^+, \cdot) = f \). Hence, by the maximum principle and the monotonicity (43) we have

\[
\inf_M f \leq u(t, x) \leq f(x) \quad \text{for all} \ (t, x) \in \mathbb{R}^+ \times M.
\]

In particular, the limit

\[
u(\infty)(x) = \lim_{t \to \infty} u(t, x)
\]

is well-defined for every \( x \in M \). The convergence \( u(t, \cdot) \to u(\infty) \) is uniform on compact subsets, \( u(\infty) \) is bounded and \( Lu(\infty) = 0 \). Since \( M \) is complete and has nonnegative Ricci curvature, the operator \( L \) enjoys a Liouville property; see Theorem 7.4 of [Saloff-Coste 1992]. In particular, \( u(\infty) \) must be constant. Since \( \inf_M f \leq u(\infty) \leq f \), it must be \( u(\infty) \equiv \inf_M f = 0 \), that is,

\[
\lim_{t \to \infty} u(t, x) = 0 \quad \text{for all} \ x \in M. \tag{48}
\]

To conclude the proof of (47), we observe that

\[
u(t, x) = \int_M H_L(x, y, t) f(y) \, dy 
\]

\[
\geq \frac{C_1}{|B_{\sqrt{t}}(x)|} \int_M \left(1 + \frac{\text{dist}(x, y)}{\sqrt{t}}\right)^{-m/2} \exp\left(-C_2 \frac{\text{dist}(x, y)^2}{t}\right) f(y) \, dy
\]

\[
= \frac{C_1}{|B_{\sqrt{t}}(x)|} \int_0^\infty \left(1 + \frac{r}{\sqrt{t}}\right)^{-m/2} \exp\left(-C_2 \frac{r^2}{t}\right) \int_{\partial B_r(x)} f(y) \, d\mathcal{H}^{m-1}(y) \, dr
\]
Since \( f \geq 0 \), by comparison we have

\[
\lim_{t \to \infty} \frac{1}{|B_{\sqrt{t}}(x)|} \int_{B_{\sqrt{t}}(x)} f(y) \, dy = 0 = \inf_M f
\]
as desired. \( \square \)

From the above result, we also obtain information on the spherical mean of \( u \). This follows from the next variant of de L'Hôpital's theorem.

**Lemma 25.** Let \( h, g \in L^\infty_{\text{loc}}(\mathbb{R}^+) \) satisfy \( h \geq 0 \), \( g > 0 \) a.e. and \( g \not\in L^1(\infty) \). Then,

\[
\text{ess lim inf}_{r \to \infty} \frac{h(r)}{g(r)} \leq \lim_{r \to \infty} \frac{\int_0^r h(t) \, dt}{\int_0^r g(t) \, dt}.
\]

**Proof.** Denote by \( A \) and \( B \), respectively, the left-hand side and right-hand side of (49). For \( A' < A \), fix \( R_0 \) such that \( h \geq A' g \) a.e. on \((R_0, \infty)\). Then, for each \( r > R_0 \),

\[
\frac{\int_0^r h(t) \, dt}{\int_0^r g(t) \, dt} = \frac{\int_0^{R_0} h(t) \, dt + \int_{R_0}^r h(t) \, dt}{\int_0^{R_0} g(t) \, dt + \int_{R_0}^r g(t) \, dt} \geq \frac{\int_0^{R_0} h(t) \, dt + A' \int_{R_0}^r g(t) \, dt}{\int_0^{R_0} g(t) \, dt + \int_{R_0}^r g(t) \, dt}.
\]

Since \( g \not\in L^1(\infty) \), letting \( r \to \infty \) along a sequence realizing \( B \) we get \( B \geq A' \), and the thesis follows by letting \( A' \uparrow A \). \( \square \)

**Corollary 26.** Let \((M^m, \langle \cdot, \cdot \rangle)\) be a complete (connected) Riemannian manifold with infinite volume. Let \( 0 \leq f \in L^1_{\text{loc}}(M) \) and \( x \in M \) and assume that

\[
\lim_{R \to \infty} \text{ess lim inf}_{R \to \infty} \frac{1}{|B_R(x)|} \int_{B_R(x)} f(y) \, dy = \inf_M f.
\]

Then

\[
\text{ess lim inf}_{R \to \infty} \frac{1}{|\partial B_R(x)|} \int_{\partial B_R(x)} f(y) \, d\mathcal{H}^{m-1}(y) = \inf_M f.
\]

**Proof.** The functions \( h \) and \( g \) defined by

\[
h(t) = \int_{\partial B_t(x)} f(y) \, d\mathcal{H}^{m-1}(y) \quad \text{and} \quad g(t) = |\partial B_t(x)| \quad \text{for all } t > 0
\]
satisfy the assumptions of the previous lemma (note that $1/g \in L^\infty_{loc}(\mathbb{R}^+)$ by [Bianchini et al. 2013, Proposition 1.6], since $M$ is noncompact). The thesis follows from the next chain of inequalities:

$$
\inf_M f \leq \text{ess lim inf}_{R \to \infty} \frac{1}{|\partial B_R(x)|} \int_{\partial B_R(x)} f(y) \, d\mathcal{H}^{m-1}(y) \, dy \\
\leq \lim_{R \to \infty} \frac{1}{|B_R(x)|} \int_{B_R(x)} f(y) \, dy \leq \inf_M f.
$$

□

We are ready to state our second main result of the section, which will enable us to prove the Hessian estimate (7). The argument below seems to be new.

**Theorem 27.** Let $(M^m, \langle \cdot, \cdot \rangle)$ be a connected, complete manifold with Ric $\geq 0$ and let $A, L$ be as in (36)–(37), with $A$ self-adjoint and smooth. If $f \in L^\infty(M)$ satisfies $Lf \leq 0$ on $M$, then for any $x \in M$

$$
\lim_{R \to \infty} \frac{R^2}{|B_R(x)|} \int_{B_R(x)} Lf(y) \, dy = 0.
$$

**Proof:** Without loss of generality, we assume $\inf_M f = 0$. Fix $x \in M$. We refer to the proof of Lemma 23 for notation, and in particular, for $t > 0$ and $a > 0$ we define $\varphi_a(y)$ and $\Omega_a$ as in (44). As already observed, $\{\Omega_a\}$ is an exhaustion of $M$, increasing as $a$ decreases. Furthermore, for almost every $a > 0$ the boundary $\partial \Omega_a$ is smooth. From the proof of Lemma 23 we get

$$
\int_{\Omega_a} f(y) \partial_t H_L(x, y, t) \, dy \leq \int_{\Omega_a} \varphi_a(y) Lf(y) \, dy.
$$

On the other hand, since $f \geq 0$, by (41) and Lemma 21 we can estimate

$$
\int_{\Omega_a} f(y) \partial_t H_L(x, y, t) \, dy \geq -\frac{C_5}{t} \frac{1}{|B_{\sqrt{t}}(x)|} \int_{\Omega_a} f(y) \left(1 + \frac{\text{dist}(x, y)}{\sqrt{t}}\right)^{\frac{m}{2}} \exp\left(-\frac{C_6 \text{dist}(x, y)^2}{t}\right) \, dy.
$$

By (40) and Lemma 21 we also have the bounds

$$
\frac{C_1}{|B_{\sqrt{t}}(x)|} \left(1 + \frac{\text{dist}(x, y)}{\sqrt{t}}\right)^{-\frac{m}{2}} \exp\left(-\frac{C_2 \text{dist}(x, y)^2}{t}\right) \leq H_L(x, y, t) \leq \frac{C_3}{|B_{\sqrt{t}}(x)|} \left(1 + \frac{\text{dist}(x, y)}{\sqrt{t}}\right)^{\frac{m}{2}} \exp\left(-\frac{C_4 \text{dist}(x, y)^2}{t}\right).
$$

Now, fix $k > 1$ large enough so that

$$
C_3(1 + s)^{\frac{m}{2}} e^{-C_4 s^2} \leq \frac{1}{2} C_1 2^{-\frac{m}{2}} e^{-C_2} \quad \text{for all } s \geq k
$$

and pick

$$
a = \frac{C_1 2^{-\frac{m}{2}} e^{-C_2}}{2|B_{\sqrt{t}}(x)|}.
$$

With this choice, we have

$$
\begin{cases}
\varphi \leq a & \text{on } M \setminus B_{k\sqrt{t}}(x), \\
\varphi \geq 2a & \text{on } B_{\sqrt{t}}(x);
\end{cases}
$$
hence $B_{r}(x) \subseteq \Omega_{a} \subseteq B_{k_{r}}(x)$ and $\varphi_{a} \geq a$ on $B_{r}(x)$. Thus, using also (51) we can estimate

\[ \begin{align*}
0 & \geq C_{i} \frac{2^{-\frac{m}{2}} e^{-C_{2}}}{2|B_{r}(x)|} \int_{B_{r}(x)} Lf(y) \, dy = a \int_{B_{r}(x)} Lf(y) \, dy \\
& \geq \int_{B_{r}(x)} \varphi_{a}(y)Lf(y) \, dy \geq \int_{\Omega_{a}} \varphi_{a}(y)Lf(y) \, dy \geq \int_{\Omega_{a}} f(y) \partial_{t} H_{L}(x, y, t) \, dy \\
& \geq -\frac{C_{5}}{t|B_{r}(x)|} \int_{\Omega_{a}} f(y) \left(1 + \sqrt{\frac{\text{dist}(x, y)}{t}}\right)^{-m} \exp\left(-C_{6} \frac{\text{dist}(x, y)^2}{t}\right) \, dy \\
& \geq -\frac{C_{7}}{t|B_{r}(x)|} \int_{B_{k_{r}}(x)} f(y) \, dy,
\end{align*} \]

where

\[ \begin{align*}
C_{7} & = C_{5} \sup\{(1 + s)^{\frac{m}{2}} e^{-C_{6}s^{2}} : s > 0\} < \infty.
\end{align*} \]

Summing up, there exists a constant $C > 0$, depending only on $C_{i}$, $1 \leq i \leq 7$, such that

\[ \begin{align*}
0 & \geq \frac{t}{|B_{r}(x)|} \int_{B_{r}(x)} Lf(y) \, dy \geq -\frac{C}{|B_{r}(x)|} \int_{B_{k_{r}}(x)} f(y) \, dy.
\end{align*} \]

Since $f \geq 0$, by the Bishop–Gromov theorem we also have

\[ \begin{align*}
0 & \geq \frac{t}{|B_{r}(x)|} \int_{B_{r}(x)} Lf(y) \, dy \geq -\frac{C_{k_{r}}^{m}}{|B_{k_{r}}(x)|} \int_{B_{k_{r}}(x)} f(y) \, dy.
\end{align*} \]

By Proposition 24 we have that the right-hand side of this inequality converges to $\inf_{M} f = 0$ as $t \to \infty$, and the conclusion follows. \hfill \Box

6. Proof of Theorem 6(ii)

Combining Corollary 18, Proposition 24 and Theorem 27, we get:

**Proposition 28.** Let $(M^{m}, \sigma)$ be a connected, complete Riemannian manifold with $\text{Ric} \geq 0$ and

\[ \text{Ric}^{(\ell)}(\nabla r) \geq -\frac{\tilde{\kappa}^{2}}{1 + r^{2}}, \quad \ell = \max\{1, m - 2\}, \]

for some $\tilde{\kappa} \in \mathbb{R}_{0}^{+}$ and where $r$ is the distance from a fixed origin. Let $u \in C_{\infty}(M)$ be a nonconstant solution to (MSE) which grows at most linearly on one side. Then, for each $x \in M$,

\[ \begin{align*}
\lim_{R \to \infty} \frac{1}{|B_{R}(x)|} \int_{B_{R}(x)} |Du|^{2} \, dx & = \sup_{M} |Du|^{2}, \\
\lim_{R \to \infty} \frac{R^{2}}{|B_{R}(x)|} \int_{B_{R}(x)} |D^{2}u|^{2} \, dx & = 0.
\end{align*} \]

**Proof.** Because of Corollary 18, in our assumptions $|Du| \in L^{\infty}(M)$; hence by (11) the operator

\[ L\phi \doteq W \Delta_{\sigma} \phi = \text{div}(W g^{ij} \phi_{x_{i}} \phi_{x_{j}}) \]

is uniformly elliptic on \( M \). By the Jacobi equation, \( f = 1 / W \) is a nonnegative solution to \( L f \leq -||II||^2 \leq 0 \), and therefore \( -W^2 \in L^\infty(M) \) satisfies \( L(-W^2) \leq 0 \). Applying Proposition 24 to \(-W^2\) and Theorem 27 to \( f \) we deduce

\[
\lim_{R \to \infty} \frac{1}{|B_R(x)|} \int_{B_R(x)} W^2 \, dx = \sup_M W^2, \tag{54}
\]

\[
\lim \sup_{R \to \infty} \frac{R^2}{|B_R(x)|} \int_{B_R(x)} ||II||^2 \, dx \leq - \lim_{R \to \infty} \frac{R^2}{|B_R(x)|} \int_{B_R(x)} L f \, dx = 0. \tag{55}
\]

From (54) we readily deduce (52). On the other hand, note that

\[
||II||^2 = W^{-2} g^{ik} u_{kj} g^{jl} u_{li} = W^{-2} \left\{ |D^2 u|^2 - 2 \left| D^2 u \left( \frac{Du}{W}, \cdot \right) \right|^2 + \left[ D^2 u \left( \frac{Du}{W}, \frac{Du}{W} \right) \right]^2 \right\}.
\]

If \( du(x) = 0 \), then \( ||II||^2 \geq W^{-2} |D^2 u|^2 \). Otherwise, let \( e_1 = Du / |Du| \) and choose a local orthonormal frame \( \{e_\alpha\} \) for \( e_1^\perp \) around \( x \), where \( 2 \leq \alpha \leq m \). Then,

\[
|D^2 u|^2 - 2 \left| D^2 u \left( \frac{Du}{W}, \cdot \right) \right|^2 + \left[ D^2 u \left( \frac{Du}{W}, \frac{Du}{W} \right) \right]^2 = \sum_{\alpha, \beta} u_{\alpha\beta}^2 + 2 \sum_{\alpha} u_{1\alpha}^2 + u_{11}^2 - 2 \frac{W^2 - 1}{W^2} \sum_j u_{1j}^2 + \frac{(W^2 - 1)^2}{W^4} u_{11}^2 \leq \sum_{\alpha, \beta} u_{\alpha\beta}^2 + \frac{2}{W^2} \sum_{\alpha} u_{1\alpha}^2 + \frac{1}{W^4} u_{11}^2 \geq W^{-4} |D^2 u|^2.
\]

Summarizing, we have \( ||II||^2 \geq W^{-6} |D^2 u|^2 \); thus from the boundedness of \( W \) and from (55) we conclude (53).

We now conclude the proof of Theorem 6 with a blow-down procedure, for which we use some basic convergence results in the theory of limit spaces and nonsmooth spaces with Ricci curvature bounded below. All the tools needed herein can be found in [Honda 2015; Ambrosio and Honda 2017; 2018].

Fix \( o \in M \), and write \( B_R = B_R(o) \). Because of Corollary 18 and Proposition 28,

\[
\lim_{R \to \infty} \frac{1}{|B_R|} \int_{B_R} |Du|^2 \, dx = \sup_M |Du|^2, \tag{56}
\]

\[
\lim \sup_{R \to \infty} \frac{R^2}{|B_R|} \int_{B_R} |D^2 u|^2 \, dx = 0. \tag{57}
\]

Consider a tangent cone at infinity \( M_\infty \) for \( M \) based at \( o \). By statement (2.1) in [De Philippis and Gigli 2018], the limit space \( M_\infty \) also supports a Borel measure \( m_\infty \) such that, up to a subsequence,

\[
(M, \lambda_n^{\n-1} \text{dist}_\sigma, \lambda_n^{-m} \, dx, o) \xrightarrow{\text{pmGH}} (M_\infty, d_\infty, m_\infty, o_\infty) \tag{58}
\]

in the pointed-measured-Gromov–Hausdorff (pmGH) sense. For the precise definition of pGH and pmGH convergence we refer to [Gigli et al. 2015]. Here, \( \{\lambda_n\} \subset \mathbb{R}^+ \), \( \lambda_n \to \infty \) as \( n \to \infty \), and \( \lambda_n^{\n-1} \text{dist}_\sigma \) is the distance function induced by the rescaled metric \( \sigma_n \equiv \lambda_n^{\n-2} \sigma \). Denote with \( D_n \) and \( dx_n \) the induced
connection and volume measure, and \(B^n_R\) the metric balls centered at \(o\) in \((M, \sigma_n)\). Therefore, \(B^n_R = B_{\lambda_n R}\). Define \(u_n = u/\lambda_n\). Then,
\[
|D_n u_n|_{\sigma_n} = |Du|, \quad |D^2_n u_n|_{\sigma_n} = \lambda_n |D^2 u|
\]
and therefore, by the Arzelà-Ascoli theorem, up to subsequences \(u_n \to u_\infty \in \text{Lip}(M_\infty)\) locally uniformly; hence \(u_n \to u_\infty\) strongly in \(L^2\) on \(B^n_\infty = B^n_{\lambda\infty}(x_\infty)\), that is,
\[
\lim_{n \to \infty} \int_{B^n_R} |u_n|^2 \, dx_n = \int_{B^n_R} |u_\infty|^2 \, d\mu_\infty,
\]
\[
\lim_{n \to \infty} \int_{B^n_R} u_n \varphi \, dx_n = \int_{B^n_R} u_\infty \varphi \, d\mu_\infty
\]
for each \(\varphi\) bounded and continuous on a metric space \(Z\) in which \((B^n_R, d_n)\) and \((B^n_\infty, d_\infty)\) are isometrically embedded and converge in Hausdorff sense, with \(o_n \to o_\infty\) and \(o_n\) the center of \(B^n_R\). From
\[
W_n \doteq \sqrt{1 + |D_n u_n|^2_{\sigma_n}} = \sqrt{1 + |Du|^2} = W.
\]
Scaling \((56)\) and \((57)\) we therefore get, for each fixed \(R > 0\),
\[
\lim_{n \to \infty} \frac{1}{|B^n_R|_{\sigma_n}} \int_{B^n_R} |D_n u_n|^2_{\sigma_n} \, dx_n = \sup_M |Du|^2,
\]
\[
\lim_{n \to \infty} \frac{R^2}{|B^n_R|_{\sigma_n}} \int_{B^n_R} |D^2_n u_n|^2_{\sigma_n} \, dx_n = 0.
\]
In particular, from Newton’s inequality \(|\Delta_n u_n|^2 \leq m|D^2_n u_n|^2_{\sigma_n}\) and the Bishop–Gromov theorem, \(|B^n_R|_{\sigma_n} \leq \omega_m^{-1} R^m / m\) we deduce
\[
\int_{B^n_R} |\Delta_n u_n|^2 \, dx_n \leq \frac{\omega_m^{-1} R^m}{|B^n_R|_{\sigma_n}} \int_{B^n_R} |D^2_n u_n|^2_{\sigma_n} \, dx_n \to 0
\]
as \(n \to \infty\), and therefore
\[
\int_{B^n_R} \varphi \Delta_n u_n \, dx_n \leq \left( \int_{B^n_R} \varphi^2 \, dx_n \right)^{\frac{1}{2}} \left( \int_{B^n_R} |\Delta_n u_n|^2 \, dx_n \right)^{\frac{1}{2}} \leq \max \{ \varphi \left[ \frac{\omega_m^{-1} R^m}{m} \right] \left( \int_{B^n_R} |\Delta_n u_n|^2 \, dx_n \right)^{\frac{1}{2}} \to 0. \)
\]
By \((62)\) and \((63)\), \(\Delta_n u_n \to 0\) strongly in \(L^2\). Combining \(u_n \to u_\infty\) strongly in \(L^2\) with
\[
\sup_n \left( \int_{B^n_R} [|u_n|^2 + |D_n u_n|^2_{\sigma_n} + (\Delta_n u_n)^2] \, dx_n \right) < \infty,
\]
we infer by [Ambrosio and Honda 2018, Theorem 4.4] that
(i) \(u_\infty \in \mathcal{D}(\Delta, B^n_\infty)\), the domain of the Laplacian on \(B^n_\infty\),
(ii) \(\Delta_n u_n \to \Delta u_\infty\) on \(B^n_R\) weakly in \(L^2\), so in particular \(\Delta u_\infty = 0\),
(iii) \(|D_n u_n|^2_{\sigma_n} \to |D_\infty u_\infty|^2_{\infty}| \) in \(L^1\)-strongly in \(B^n_R\) for each \(r < R\).
In particular, setting $P \doteq \sup_M |Du|^2$, from (59) and (60) we get
\[
\lim_{n \to \infty} \int_{B_R^n} \left| D_n u_n \right|^2 - P \right| \, dx_n \leq \frac{\omega_{m-1}^{-1} R^m}{|B_R^n|_{\sigma_n}} \int_{B_R^n} (P - |Du_n|^2_{\sigma_n}) \, dx_n = 0.
\]
Using (iii) and [Bruè et al. 2023, Proposition 1.27(i)] (see also [Ambrosio and Honda 2017]), we therefore deduce $|D_n u_n|^2_{\sigma_n} - P \to |D_n u_{\infty}|^2_{\sigma_n} - P$ strongly in $L^1$ on $B_r^\infty$ for each $r < R$, and thus
\[
0 = \lim_{n \to \infty} \int_{B_R^n} \left| D_n u_n \right|^2 - P \right| \, dx_n = \int_{B_r^\infty} \left| D_n u_{\infty} \right|^2 - P \right| \, dm_{\infty}.
\]
Concluding, $u_{\infty}$ solves
\[
\Delta u_{\infty} = 0, \quad |D_n u_{\infty}|^2 = P \neq 0
\]
on the RCD$(0, m)$ space $(M_{\infty}, d_{\infty}, m_{\infty}, x_{\infty})$. Bochner inequality (see [Honda 2015, Theorem 1.4]) guarantees that $|D^2 u_{\infty}| \equiv 0$ on $M_{\infty}$. One concludes that $M_{\infty} = N \times \mathbb{R}$ by using [Antonelli et al. 2019, Lemma 1.21].

7. Proof of Theorem 11

If $M$ is parabolic, clearly the result follows from Theorem 6. If $M$ is nonparabolic, the argument goes as in [Ding et al. 2016, Theorem 3.6], so we only sketch the main steps. In our assumptions, by Corollary 18, $|Du| \in L^\infty(M)$; hence $L = W \Delta_g$ is uniformly elliptic. The Harnack inequality in [Saloff-Coste 1992] together with (5) imply that $|u(x)| = o(r(x))$ as $x$ diverges. By a standard cutoff argument using $Lu = 0$, the next Caccioppoli inequality holds: for each $\varphi \in \text{Lip}_c(M)$
\[
\int_M \varphi^2 |Du|^2 \, dx \leq 4\alpha^2 \int_M u^2 |D\varphi|^2 \, dx.
\]
(64)
In particular, having fixed $\varepsilon > 0$, by condition $u = o(r)$ we can also fix $R_0 = R_0(\varepsilon) > 0$ such that for every $R \geq R_0$ we have $u^2 \leq \varepsilon R^2$ on $B_{2R}$. Considering the Lipschitz cutoff function $\varphi$ which is 1 on $B_R$, 0 outside of $B_{2R}$ and satisfies $|D\varphi| \leq 1/R$, we get
\[
\int_{B_R} |Du|^2 \, dx \leq \frac{4\alpha^2}{R^2} \int_{B_{2R}\setminus B_R} u^2 \, dx \leq \varepsilon |B_{2R}| \leq C\varepsilon |B_R|
\]
for every $R \geq R_0$, where we used the doubling property on $M$ coming from condition Ric $\geq 0$. From (52) we finally infer
\[
\sup_M |Du|^2 = \lim_{R \to \infty} \frac{1}{|B_R|} \int_{B_R} |Du|^2 \, dx \leq C\varepsilon,
\]
and the thesis follows by letting $\varepsilon \to 0$.

8. Proof of Corollary 10

By Theorem 6, $|Du| \in L^\infty(M)$ and any tangent cone at infinity of $M$ splits off a line. It is a general fact that, if Sec $\geq 0$, a tangent cone splits if and only if $M$ itself splits. A proof of this result can be found in
Therefore, it remains to prove that \( u \) only depends on the coordinate of a split line. Write \( M = N^{m-1} \times \mathbb{R} \) with coordinates \((y_1, s_1)\), for some complete manifold \( N^{m-1} \) with \( \text{Sec} \geq 0 \), and consider the function \( v_1 = \sigma(Du, \partial_s) \), which by (15) satisfies \( Lv_1 = 0 \) on \( M \), where we set

\[
L \phi = W^{-1} \mathcal{L}_W \phi = \text{div}(W^{-1} g^{ij} \phi_i \partial_j).
\]

Our gradient estimate guarantees that \( v_1 \) is bounded and that \( L \) is uniformly elliptic on \( M \), and therefore, by [Saloff-Coste 1992, Theorem 7.4] we deduce that \( v_1 \) is constant on \( M \). Hence,

\[
u(y_1, s_1) = a_1 s_1 + b_1 + u_2(y_1) \sqrt{1 + a_1^2}
\]

for some smooth function \( u_2 : N^{m-1} \to \mathbb{R} \) and some \( a_1, b_1 \in \mathbb{R} \). One easily checks that \( u_2 \) solves (MSE) on \( N^{m-1} \). Since \( u_2 \) has at most linear growth on one side, and \( N^{m-1} \) has nonnegative sectional curvature, by the first part of the proof we deduce that either \( u_2 \) is constant or that \( N^{m-1} = N^{m-2} \times \mathbb{R} \) and \( u_2(y_2, s_2) = a_2 s_2 + b_2 + u_3(y_2) \sqrt{1 + a_2^2} \). Iterating, we can write \( M = N^{m-k} \times \mathbb{R}^k \) for some \( k \in \{1, \ldots, m-2\} \) and for some complete manifold \( N^{m-k} \) with \( \text{Sec} \geq 0 \), and

\[
u(z, (s_1, \ldots, s_k)) = \sum_{j=1}^{k} a_j s_j + b + u_{k+1}(z) \sqrt{1 + a_k^2}
\]

for some \( a_i, b \in \mathbb{R} \) and \( u_{k+1} : N^{m-k} \to \mathbb{R} \). Indeed, we can continue the iteration procedure up until either \( u_{k+1} \) is constant, or \( k = m-2 \) and \( u_{m-1} \) is nonconstant. In the latter case, observe that \( N^2 \) is a complete surface with \( \text{Sec} \geq 0 \); hence \( N^2 \) is parabolic. Being \( u_{m-1} \) nonconstant, both \( N^2 \) and \( u_{m-1} \) split as indicated in Theorem 6(i). Summarizing, in each case we can conclude that \( M = N^{m-k} \times \mathbb{R}^k \) for some \( k \in \{1, \ldots, m-1\} \), and that

\[
u(z, (s_1, \ldots, s_k)) = \sum_{j=1}^{k} a_j s_j + b
\]

for some \( b \in \mathbb{R} \), as required. It is therefore sufficient to consider the splitting \( \mathbb{R}^k = \mathbb{R}^{k-1} \times \mathbb{R} \) along a line in direction \((a_1, \ldots, a_k)\) to get the desired splitting \( M = N \times \mathbb{R} \) of \( M \) in such a way that \( u(y, s) = \alpha s + b \).

9. Proof of Proposition 9

The following example is essentially that in [Kasue and Washio 1990, p. 913]. Let \( m \geq 4 \). We consider a manifold \((P^{m-2}, h)\) and smooth functions \( f, \eta \in C^\infty(\mathbb{R}^+) \) to be chosen later, and define the following metric on \( M = \mathbb{R} \times \mathbb{R}^+ \times P \):

\[
\sigma = f(r)^2 \, dt^2 + dr^2 + \eta(r)^2 h.
\]

To compute the curvatures of \( M \), we use the index agreement \( 1 \leq a, b, c, l \leq m, \ 3 \leq \alpha, \beta, \gamma, \delta \leq m \). Let \( \{\theta^a\} \) be a local orthonormal coframe on \( P \), with associated connection forms \( \omega^a_\beta \) obeying the structure equations

\[
\begin{align*}
d\theta^a &= -\omega^a_\beta \wedge \theta^\beta, \\
\omega^\beta_\beta &= -\omega_\beta^a
\end{align*}
\]
Assume that \( (R, \mathbb{R}^+, P) \) are implicit. Differentiating, one checks that the forms
\[
\bar{\omega}^1 = 0, \quad \bar{\omega}^2 = \frac{\eta'}{\eta} \bar{\theta}^1, \quad \bar{\omega}^\beta = \omega^\beta, \quad \bar{\omega}^1 = -\frac{f'}{f} \bar{\theta}^1
\]
satisfy the structure equations on \( M \) for the coframe \( \{\bar{\theta}^\alpha\} \); hence they are the connection forms of \( \{\bar{\theta}^\alpha\} \).

The associated curvature forms \( \bar{\Theta}^\alpha = d\bar{\omega}^\alpha + \bar{\omega}^\alpha \wedge \bar{\omega}^\beta \) are therefore
\[
\bar{\Theta}^\alpha = -\frac{\eta' f'}{\eta f} \bar{\theta}^\alpha \wedge \bar{\theta}^1, \quad \bar{\Theta}^\alpha = \frac{\eta''}{\eta} \bar{\theta}^2 \wedge \bar{\theta}^\alpha, \\
\bar{\Theta}^\alpha = \bar{\Theta}^\alpha - \left(\frac{\eta'}{\eta}\right)^2 \bar{\theta}^\alpha \wedge \bar{\theta}^\beta, \quad \bar{\Theta}^2 = -\frac{f''}{f} \bar{\theta}^2 \wedge \bar{\theta}^1.
\]

The components \( R^\alpha_{\beta\gamma\delta} \) and \( \tilde{R}^\alpha_{\beta\gamma\delta} \) of the (3, 1) curvature tensors of, respectively, \( P \) and \( M \), are given by the identities
\[
\Theta^\alpha_\beta = \frac{1}{2} R^\alpha_{\beta\gamma\delta} \theta^\gamma \wedge \theta^\delta, \quad \tilde{\Theta}^\alpha_\beta = \frac{1}{2} \tilde{R}^\alpha_{\beta\gamma\delta} \bar{\theta}^\gamma \wedge \bar{\theta}^\delta,
\]
and thus, from (66), we deduce
\[
0 = \tilde{R}^2_{12\alpha} = \tilde{R}^2_{1\alpha 1} = \tilde{R}^2_{1\alpha \beta} = \tilde{R}^2_{1\beta 1} = \tilde{R}^2_{2\gamma \delta}, \quad \tilde{R}^2_{121} = -\frac{f''}{f}, \quad \tilde{R}^2_{1\beta 1} = -\frac{\eta' f'}{\eta f} \delta^\alpha_\beta, \quad \tilde{R}^2_{2\beta 2} = -\frac{\eta''}{\eta} \delta^\alpha_\beta,
\]
\[
\tilde{R}^\alpha_{\beta\gamma\delta} = \frac{1}{\eta^2} R^\alpha_{\beta\gamma\delta} = \left(\frac{\eta'}{\eta}\right)^2 [\delta^\alpha_\gamma \delta^\beta_\delta - \delta^\alpha_\delta \delta^\beta_\gamma].
\]

Assume that \( (P, h) \) is the round sphere with curvature 1, and let \( \{e_\alpha\} \) and \( \{\bar{c}_\alpha\} \) be, respectively, the dual frames of \( \{\theta^\alpha\} \) and \( \{\bar{\theta}^\alpha\} \). From (67) we deduce that the curvature operator is diagonalized by the simple planes \( \{\bar{c}_a \wedge \bar{c}_b\} \), so for \( m \geq 4 \) we get

\[
|\text{Sec}(\pi)| \leq \max\left\{ \frac{f''}{f}, \frac{\eta' f'}{\eta f}, \frac{1 - (\eta')^2}{\eta^2}, \frac{\eta''}{\eta} \right\}.
\]

In [Kasue and Washio 1990], the authors chose the following functions \( f, \eta \): given \( \alpha, \beta \in (0, 1) \) such that \( m - 1 - \beta > 2 + \alpha \), let \( 0 < \xi_1, \xi_2 \in C^\infty(\mathbb{R}^+) \) satisfy
\[
\xi_1(t) = \begin{cases} 
 t & \text{if } t \in (0, 1], \\
 t^{-1-\alpha} & \text{if } t \in [2, \infty),
\end{cases} \quad \xi_2(t) = \int_1^t \xi_1(s) \, ds.
\]

Then, for \( b, c \in \mathbb{R}^+ \) they defined
\[
\eta(r) = \frac{1}{2} r + \frac{1}{2 \xi_2(0)} \int_0^r \xi_2(s) \, ds, \quad f(r) = (b + r^2) \frac{\xi_2(s) - \xi_2(0)}{2} + c.
\]
Note that with such a choice the metric extends in a $C^2$ way at $r = 0$, giving rise to a complete manifold. Since the curvature operator is diagonalized by $\{e_a \wedge \tilde{e}_b\}$,

$$\overline{\text{Ric}}^{(2)} \geq \min \left\{ -\frac{f''}{f} + \frac{1 - (\eta')^2}{\eta^2} - \frac{f''}{\eta f}, -\frac{f''}{\eta f} - \frac{\eta''}{\eta}, \frac{1 - (\eta')^2}{\eta f}, 1 - (\eta')^2 \frac{\eta'}{\eta^2} - \frac{\eta''}{\eta} - \frac{\eta' f'}{\eta f}, 2 \frac{1 - (\eta')^2}{\eta^2}, -2 \frac{\eta''}{\eta} \right\}. \tag{68}$$

By the expression of $\eta$, $f$, the four terms in the second line of (68) are positive, and it is easy to see that, when $b$, $c$ are large enough, the three terms in the first line are positive as well. The two terms in the third line are positive except at $r = 0$. Whence, $\overline{\text{Ric}}^{(2)} \geq 0$, and moreover $|\overline{\text{Sec}}| \leq \bar{\kappa}^2$ holds for a suitable $\bar{\kappa} > 0$. Moreover, from the fact that $\overline{\text{Ric}}$ is diagonal in the basis $\{e_a\}$ with

$$\overline{\text{Ric}}_{11} = -\frac{f''}{f} - (m-3) \frac{\eta' f'}{\eta f}, \quad \overline{\text{Ric}}_{22} = -\frac{f''}{f} - (m-3) \frac{\eta''}{\eta}, \quad \overline{\text{Ric}}_{\alpha\beta} = \left[ -\frac{\eta' f'}{\eta f} + (m-3) \frac{1 - (\eta')^2}{\eta^2} \right] \delta_{\alpha\beta},$$

we deduce that $\text{Ric} > 0$ if $b$, $c$ are chosen large enough. To construct linearly growing minimal graphs, consider a function $u : M \to \mathbb{R}$ of the coordinate $t$ alone. It follows that $du = u_a \tilde{\partial}^a$ with $u_1 = (\partial_t u)/f$ and $u_a = 0$ for $a \geq 2$. The components of the Hessian $D^2 u$ obey the relation

$$u_{ab} \tilde{\partial}^b = du_a - u_c \tilde{\partial}^c_a,$$

and from the expression of $\tilde{\partial}^a_\alpha$ we get

$$u_{11} = \frac{\partial_t^2 u}{f^2}, \quad u_{21} = -\frac{f'}{f^2} \partial_t u, \quad u_{1\alpha} = u_{2\alpha} = u_{\alpha\beta} = 0.$$ 

In particular, setting $W = \sqrt{1 + |Du|^2} = \sqrt{1 + u_1^2}$,

$$\text{div} \left( \frac{Du}{\sqrt{1 + |Du|^2}} \right) = \Delta u - \frac{D^2 u(Du, Du)}{W^3} = \frac{\partial_t^2 u}{f^2 W} - \frac{(\partial_t^2 u) u_1^2}{f^2 W^3} = \frac{\partial_t^2 u}{f^2 W^3}.$$

It follows that any affine function $u(t) = at + b$ gives rise to a minimal graph. Furthermore, $|Du| = a/f$ is bounded on $M$ since $f$ is bounded below by a positive constant, thus $u$ has at most linear growth.

**Appendix**

Let $M$ be a connected, complete Riemannian manifold with nonnegative Ricci curvature, $\dim M = m$, and let $A$, $L$, $H_L$ be as in Section 5. In this Appendix, we discuss the two-sided bound in (40) for $H_L$. While the upper bound is shown in [Saloff-Coste 1992], the argument for the lower bound is merely indicated with no proof. The approach relies on the following parabolic Harnack inequality in [Saloff-Coste 1992, Corollary 5.4]: given $p \in M$, $R > 0$, $T > 0$ and $\delta \in (0, 1)$, if $u$ is a positive solution to $\partial_t u = Lu$ on
for every \( x, y \in B_{\delta R}(p) \) and \( 0 < t < s < T \), with \( C = C(m, \delta, \alpha) > 0 \). A note of warning: in [Saloff-Coste 1992, Corollary 5.4], the final +1 in brackets in (69) is missing. However, necessity of this correction becomes apparent by direct inspection of Moser’s original proof [1964, pages 110–112] in Euclidean setting (the analogue of (69) is [Moser 1964, Formula (1.5)]). For the reader’s convenience, we give a proof that the lower bound in (40) follows from the upper one coupled with (69), along the lines of the argument developed by Aronson and Serrin [1967] in the Euclidean case. A few observations are in order.

First, in view of Lemma 21 the upper bound in (40) implies

\[
H_L(x, y, t) \leq \frac{C’_3}{|B_{\sqrt{t}}(x)|} \exp\left(-C’_4 \frac{\text{dist}(x, y)^2}{t}\right) \quad \text{for all } x, y \in M, \ t > 0,
\]

(70)

with \( C’_3, C’_4 > 0 \) depending only on \( m \) and \( \alpha \) (the ellipticity constant of \( A \)). Secondly, the differential Harnack inequality (69) applied to \( u = H_L(x, \cdot, \cdot) \) yields

\[
H_L(x, y_1, t_1) \leq H_L(x, y_2, t_2) \exp\left(C \frac{\text{dist}(y_1, y_2)^2}{t_2 - t_1} + C \frac{t_2}{t_1}\right)
\]

(71)

for every \( y_1, y_2 \in M \) and \( 0 < t_1 < t_2 < \infty \), with \( C = C(m, \alpha) > 0 \). Lastly, note that if we have the validity of a lower bound of the form

\[
H_L(x, y, t) \geq \frac{C_1}{|B_{\sqrt{t}}(x)|} \exp\left(-C_2 \frac{\text{dist}(x, y)^2}{t}\right) \quad \text{for all } x, y \in M, \ t > 0,
\]

(72)

with \( C_1, C_2 > 0 \) depending only on \( m \) and \( \alpha \), then, again by Lemma 21, a lower bound as that in (40) holds for suitable constants \( C_1 \in (0, C’_1) \) and \( C_2 > C’_2 \) depending only on \( C_1’, C_2’ \) and \( m \). Hence, we limit ourselves to the proof that (72) follows from (70) and (71) under the assumption \( \text{Ric} \geq 0 \).

Fix a constant \( c_0 > 2 \) such that

\[
\gamma \doteq m C_3’ \int_{\sqrt{c_0}}^{+\infty} s^{m-1} e^{-C_3 s^2} \, ds < 1.
\]

(73)

Let \((x, y, t) \in M \times M \times \mathbb{R}^+\) be given. By (71) we have

\[
H_L\left(x, x, \frac{t}{2}\right) \leq H_L(x, y, t) \exp\left(2C \frac{\text{dist}(x, y)^2}{t} + 2C\right)
\]

(74)

and also

\[
H_L\left(x, z, \frac{t}{c_0}\right) \leq H_L\left(x, x, \frac{t}{2}\right) \exp\left(c^*_0 C \frac{\text{dist}(x, z)^2}{t} + \frac{c_0}{2} C\right)
\]

for every \( z \in M \), with

\[
c^*_0 = \frac{2c_0}{c_0 - 2} = \left(\frac{1}{2} - \frac{1}{c_0}\right)^{-1}.
\]
Integrating on $B_{\sqrt{t}}(x)$ we get
\[
\int_{B_{\sqrt{t}}(x)} H_L(x, z, \frac{t}{c_0}) \, dz \leq e^{(c_0^2 + \frac{t}{2}c_0)C} |B_{\sqrt{t}}(x)| H_L\left(x, x, \frac{t}{2}\right). \tag{75}
\]
Putting together (74) and (75) we obtain
\[
H_L(x, y, t) \geq e^{-\left(2 + \frac{1}{2}c_0 + c_0^2\right)C} \exp\left(-2C \frac{\text{dist}(x, y)^2}{t}\right) \int_{B_{\sqrt{t}}(x)} H_L\left(x, z, \frac{t}{c_0}\right) \, dz. \tag{76}
\]
From the upper bound (70) and the coarea formula we have
\[
\int_{M \setminus B_{\sqrt{t}}(x)} H_L(x, z, \frac{t}{c_0}) \, dz \leq C_3' \int_{\sqrt{t}}^{\infty} \frac{|\partial B_{r}(x)|}{|B_{\sqrt{t}/c_0}(x)|} \exp\left(-c_0C_4'r^2/t\right) \, dr
\]
\[
= C_3' \int_{\sqrt{t}/c_0}^{\infty} \frac{\sqrt{t}/c_0|\partial B_{\sqrt{t}/c_0}(x)|}{|B_{\sqrt{t}/c_0}(x)|} \exp(-C_4's^2) \, ds,
\]
where we have changed variable $s = r\sqrt{c_0/t}$. Since $\text{Ric} \geq 0$ we have
\[
\frac{\sqrt{t}/c_0|\partial B_{\sqrt{t}/c_0}(x)|}{|B_{\sqrt{t}/c_0}(x)|} \leq s^{m-1} \frac{\sqrt{t}/c_0|\partial B_{\sqrt{t}/c_0}(x)|}{|B_{\sqrt{t}/c_0}(x)|} \leq m s^{m-1},
\]
where the first inequality follows by the Bishop–Gromov theorem and the second from the inequality $R|\partial B_{R}(x)| \leq m|B_{R}(x)|$, holding for every $R > 0$ and for any base point $x$ on a Riemannian manifold with $\text{Ric} \geq 0$; see for instance [Li 1986, Formula (19)]. Substituting in the above estimate and recalling (73) and Lemma 22 we get
\[
\int_{B_{\sqrt{t}}(x)} H_L(x, z, t/c_0) \, dz = 1 - \int_{M \setminus B_{\sqrt{t}}(x)} H_L(x, z, t/c_0) \, dz \geq 1 - \gamma > 0
\]
and from (76) we obtain
\[
H_L(x, y, t) \geq \frac{C'_1}{|B_{\sqrt{t}}(x)|} \exp\left(-2C \frac{\text{dist}(x, y)^2}{t}\right).
\]
where $C'_1 = (1 - \gamma)e^{-(2+c_0/2+c_0^2)C} > 0$ only depends on $m$ and $\alpha$. This proves (72).

Acknowledgement

This work was done when Gama was a professor at Universidade Federal Rural do Semi-Árido, Caraúbas, and he thanks the institution for the fruitful working environment.
