A high iodine intake, thyroid diseases and the prevalence of papillary carcinoma (PTC)

George Zhu*

The Institute of Oncology, Tehran University of Medical Sciences, Tehran, Iran

Abstract

Iodine is a trace element that is essential for the synthesis of thyroid hormone. Both chronic iodine deficiency or iodine excess have been associated with hypertrophy and hyperplasia of follicular cells and the influence of thyroid hormone (T3, T4) and thyrotropin (TSH) secretion. Increase rates of the thyroid cancer are increasing after radiation exposure to 131I in children or adolescents. In respectively, dietary iodine excess goiter, iodine induced hyperthyroidism (IIH) and IIT, Iodine intake and the prevalence of papillary carcinoma (PTC), as well as the case-control and cohort studies of thyroid cancer and intake of seafood and milk products, were reviewed. Moreover, available evidence of oncogenic thyroid hormone receptor mutants from animal experiments and clinical investigation have been a shift toward the oncogenic function of human thyroid carcinoma, and its target therapy.

Introduction

The main function of the thyroid gland is to make hormones (Figure 1) [1], T4 and T3, which are essential for the regulation of metabolic effects for instance increased lipogenesis, ketogenesis, and cellular proliferation and differentiation such as the rapid development of frogs from thyrectomized tadpoles, the induction of growth hormone in the pituitary and the development of the brain in neonatal by promoting dendrite formation and myelination.

Iodine is a trace essential raw element where 65% of T4 weight is iodine [2]. Ingested iodine is absorbed and carried in the circulation as iodide. Intracellular iodide across the plasma membrane of thyrocytes by the sodium/iodide symporter is transported in the lumen of thyroid follicles. Meanwhile, the thyrocyte endoplasmic reticulum synthesizes two key proteins, TPO (thyroperoxidase) and Tg (thyroglobulin). Tg is a 660 KDa glycoprotein secreted into the lumen of follicles, whose tyrosyles serve as substrate for iodination and hormone formation. TPO sites at the apical plasma membrane, where it reduces H2O2, elevating the oxidation state of iodide to an iodinating species, and attaches the iodine to tyrosyls in Tg. H2O2 is generated at apex of the thyrocyte by Duox, a NADPH oxidase. Initial iodination of Tg products MIT and DIT. Further iodination couples two residues of DIT produce T4 at residues 5 in the Tg polypeptide chain (Figure 2). After Tg digestion, T4 and T3 are released into circulation. Nonhormonal iodine is retrieved intrathyroidally by DEHAL1, an iodotyrosine deiodinase and made available for recycling within the gland. Iodine supply, either too much or too little, impairs adequate synthesis of thyroid hormone. According to WHO/UNICEF/ICCIDD [3,4], daily iodine intake is 90 ug for infants and young children (0-59 months), 120 ug for children 6-12 years, 150 ug for adolescents and adults, and 250 ug for pregnant and lactating women. In this paper, considering that iodine deficiency endemic goiter and iodine deficiency goiter and deficiency of thyroid hormone synthesis and secretion (Cretinism) and defective thyroid hormone receptor alpha are well clinical established and readily understandable, we are deliberating the topic entity of iodine excess induced thyroid diseases and papillary carcinoma (PTC).

Induction of thyroid neoplasm in rat

In rats development of thyroid neoplasm following radioactive iodine was well established in earlier comparative experiments in 1950-1964 last century [5-8]. Recent, thyroid tumor-promoting effects of iodine deficiency and excess have also been investigated in two-stage models in rats given carcinogens, such as N-bis (2-hydroxypropyl)-nitrosamine (BHPN) or N-nitrosomethylurea (NNU). In rats exposure to N-nitrosobis (2-hydroxypropyl) amine (BHP) and an excessive iodine diet [9], the incidence of thyroid cancer was 29% in those fed the excessive iodine diet versus 33% in those fed the iodine sufficient diet. Kanno, et al. [10] examined the potential thyroid tumor-promoting effects of iodine deficiency and excess for 26 weeks in rats given saline or BHPN. In saline-treated rats, iodine deficiency or excess alone was not carcinogenic, but in BHPN-treated rats, both iodine deficiency and excess increased thyroid follicular tumors, with iodine deficiency having a markedly stronger effect (Figure 3a). The incidence of rats with benign nodules was 100% in both group. Boltze [11] fed rats over a period of 110 weeks high (~10 fold of normal), normal, and low (~0.1 fold of normal) daily iodine intake and subjected them to single external radiation of 4 gray (Gy) or sham radiation. Alone, both iodine deficiency and excess increased the thyrocyte proliferation rate and induced thyroid adenomas, but induced no thyroid carcinomas. Combined with radiation, both iodine deficiency and iodine excess induced thyroid carcinomas (PTC and follicular thyroid carcinomas, FTC) in 50-80% of animals, while iodine sufficient animals did not develop thyroid carcinomas (Figure 3b). These data suggest both long-term iodine deficiency and excess are insufficient to stimulate thyroid...
carcinogenesis, but both promote thyroid carcinogenesis induced by radiation. These less convincing evidence suggest that iodine excess may be a weak promoter of thyroid cancer.

Prevalence of animals with thyroid adenoma and thyroid carcinoma at week 26 after a single 2.8 mg/kg DHPN dose at week 2 and under one of seven long-term deficient, sufficient or excessive iodine diets (deficient intake: 0.25, 0.4, 0.55, 0.84 μg/day; normal intake: 2.6 μg/day; excessive intake: 760, 3000 μg/day). b Prevalence of animals with thyroid adenoma and thyroid carcinoma at week 110 after a single exposure to 4-Gy external radiation at week 6 and under one of three long-term deficient, sufficient or excessive iodine diets (deficient intake: 0.42 μg/100 g body weight/day; normal intake: 7 μg/100 g body weight/day; excessive intake: 72 μg/100 g body weight/day). Shaded area: range of normal iodine intake (Data from Zimmermann MB, et al. [12]).

### Radiation exposure and risk of thyroid cancer in man

External radiation to the thyroid increases risk of thyroid cancer, particularly when the radiation occurs in children or adolescents [12-20]. The Chernobyl nuclear accident in 1986 exposed population of Belarus, Ukraine, and the Russian Federation to internal radiation from radioactive iodines deposited in the thyroid, resulting in sharp
Zhu G (2017) A high iodine intake, thyroid diseases and the prevalence of papillary carcinoma (PTC)

In the 7-9-year-old, the median value of thyroid volume was 4.7 ml (normal children 4.0-4.8 ml) [24]. The main finding of close correlation between increased in thyroid volume and high iodine intake in children is based mainly on data from coast Hokkaido in 1962-69. The incidence of endemic coast goiter among students had 6.8% to 8.9%, but never been documented to be >25% [25,26]. Niepominszoze [27] examined the epidemiology of palpable goiter at the population of the metropolitan area of Greater Buenos Aires (11 million inhabitants), an iodine sufficient area. In the Random Group, goiter prevalence of 8.7% while in the Induced Group, which conclude among relatives of patients with thyroid disorders and other complaints, it climbed to 14.4%. Both group were mostly made up of women (87.2%). The epidemic data presented the fist arising from a screening survey carried out in a large iodine-sufficient population of the Southernmost of the American Continent.

To study the effect of excess iodine and excess tyrosine on goiter in mice [28], high iodine feed (high iodine and adequate tyrosine, HIAT) could result in the typical colloid goiter in mice and the goiter rate was 89.5%, whereas 35% of goiter was observed in both iodine and tyrosine excess (HIHT), and no goiter was noted in only high tyrosine (AIHT) (Figure 4), which implicate that both iodine and tyrosine played important role in goiter, with iodine excess having a markedly stronger effect, and which characterized by large follicles with flat epithelium and abundant colloid mixed with normal or larger-sized follicles lined by epithelium of increased thyroid weight. Moreover, there existed positive association between goiter rate of mice and iodine (KI) doses [29]. The differential goiter rate of 10%, 50% and 90% could be induced by drinking water containing different iodine doses accordingly 250, 1500 and 3000 ug/L respectively. The dose of iodine 250 ug/L was able to induce colloid goiter in mice. The findings were compatible with the epidemiologic results by authors in man. Iodine content in drinking water was 244.63, 533.83, 963.75 and 1570.0 ug/L versus 6.4%, 32.4%, 37.14% and 43.71% of goiter respectively [29].

Accumulated data, in the past decades, there have been at least 46 reported cases of goiter in man associated with iodine (KI, NaI, Lugol solution and antiarrhythmic agent amiodarone). From epidemiology, in China, there were 16% rate incidence of iodine goiter for tangle salt diet (iodine content 1089.2 ug/kg); and 28.36% (total 4344 analyses) rate incidence of iodine goiter in higher iodine drinkers from deep well water (iodine content 661.2 ug/L) compared to 8.37% (4158) of goiter in low iodine water drinker (iodine content 27.2 ug/L) [30]. In China, children’s goiter rate in excessive iodine regions with iodized salt was higher than that of without iodine salt 12.1% vs. 8.6% [31]. In Jinan, among 725 inhabitant’s investigations, thyroid goiter rate was 4.8% (35/725). The UIC (urinary iodine concentration) in 725 subjects from 29 rural areas were 327.0 ug/l (range 35-3938.5 ug/l), and water iodine content from 376 samples of drinking water 112.1-91.3 ug/L in mean, 90.3 ug/l (range 0.5-605.2 ug/l in medium) [32]. Table 1 presented partly the occurrence rate of coast goiter as below.

Iodine excess goiter - A diverse etiological subtype of goiter

In the 7-9-year-old, the median value of thyroid volume was 4.7 ml (normal children 4.0-4.8 ml) [24]. The main finding of close correlation between increased in thyroid volume and high iodine intake in children is based mainly on data from coast Hokkaido in 1962-69. The incidence of endemic coast goiter among students had 6.8% to 8.9%, but never been documented to be >25% [25,26]. Niepominszoze [27] examined the epidemiology of palpable goiter at the population of the metropolitan area of Greater Buenos Aires (11 million inhabitants), an iodine sufficient area. In the Random Group, goiter prevalence of 8.7% while in the Induced Group, which conclude among relatives of patients with thyroid disorders and other complaints, it climbed to 14.4%. Both group were mostly made up of women (87.2%). The epidemic data presented the fist arising from a screening survey carried out in a large iodine-sufficient population of the Southernmost of the American Continent.

To study the effect of excess iodine and excess tyrosine on goiter in mice [28], high iodine feed (high iodine and adequate tyrosine, HIAT) could result in the typical colloid goiter in mice and the goiter rate was 89.5% whereas 35% of goiter was observed in both iodine and tyrosine excess (HIHT), and no goiter was noted in only high tyrosine (AIHT) (Figure 4), which implicate that both iodine and tyrosine played important role in goiter, with iodine excess having a markedly stronger effect, and which characterized by large follicles with flat epithelium and abundant colloid mixed with normal or larger-sized follicles lined by epithelium of increased thyroid weight. Moreover, there existed positive association between goiter rate of mice and iodine (KI) doses [29]. The differential goiter rate of 10%, 50% and 90% could be induced by drinking water containing different iodine doses accordingly 250, 1500 and 3000 ug/L respectively. The dose of iodine 250 ug/L was able to induce colloid goiter in mice. The findings were compatible with the epidemiologic results by authors in man. Iodine content in drinking water was 244.63, 533.83, 963.75 and 1570.0 ug/L versus 6.4%, 32.4%, 37.14% and 43.71% of goiter respectively [29].
Zhu G (2017) A high iodine intake, thyroid diseases and the prevalence of papillary carcinoma (PTC)

Iodine induced hyperthyroidism (IIT) and thyrotoxicosis

According to WHO above in 1994 [33] and the Korea Centers for disease control and prevention (KCDC) in 2012 (34)] food products such as processed, agricultural, meats, and marine products were monitored for measuring dietary iodine. The recommended iodine daily allowance of 70-150 ug [35]. An excess of iodine through dietary intake, drugs or other iodine-containing compounds can lead to goiter [36,37], hyperthyroidism [38-45], hashimoto’s thyroiditis [46] and thyrotoxicosis [47-54] through increasing thyroid hormone synthesis in the presence of underlying thyroid disease, particularly multinodular goiters containing previously existing area of autonomous function. In 1958, Introduction of potassium iodide (KI) in order to the prevention of goiter in French, many students developed iodine goiter with oral high dosage of 1% KI or 10 mg KI daily. Until now, in literature, there were at least 22 cases reports on IIH or IIT. Potassium iodide (KI) at 10–4–10–7 mol/L concentration stimulate the proliferation of thyroid cancer BPH 10–3 cells, increased levels of serum T3 and T4, increased cyclin D1 mRNA and protein (Nie, 2005; Li, 2013). In rats serum thyroxine (TT4, FT4, rT3) was higher in higher iodine than the result in lower iodine (Nie, 2005).

Iodine-induced hyperthyroidism (IHH) has been frequently described when iodine is introduced into an iodine-deficient area [38], patients residing in iodine-sufficient areas [43] and iodinated preparation for water purification [40]. Excessive iodine intake might also be due to a long-term topical exposure (iodine solution dressing or topical iodine application) or by intravenous administration of iodine-containing substances [39,41,45,55]. In a classical study, four euthyroid patients with a single autonomous nodule from the slightly iodine-deficient Brussels region received a supplement of 500 ug iodine per day. This caused a slow but constant increase of thyroid hormone. After four weeks, the patients became hyperthyroid [47]. Therefore, individuals with multinodular goiters living in iodine-replete regions can also develop hyperthyroidism, confirming that nodular goiters are particularly prone to developing IIT [48]. Iodine-induced IIT was recognized as early as 1821 by Coindet [40], who reported that goitrous individuals treated with iodine developed hyperthyroidism. Comparative survey of thyrotoxicosis epidemiology in East-Jutland Denmark and Iceland, it occurs that high incidence of multinodular toxic goitre in the elderly population in a low iodine intake area whereas high incidence of Grave’s disease in young in a high iodine intake area [56]. In northern Tasmania in UK, in 1964 and in 1971 respectively, the incidence of thyrotoxicosis rose substantially because of the addition of iodate to bread to prevent goitre or iodine residues in milk [51]. In Vigo, Spain, dietary of iodine supplementation in iodine sufficient areas may induce the increase of thyrotoxicosis (TT) (7.68/100,000), as opposed to 3.1/100,000 in area without iodized salt [57]. IIT has been reported after initiating iodine supplementation, also with use of iodinated drugs, radiographic contrast agents and food dietary iodine [48-58] (Table 1). Table 1 present iodine-containing compounds related to IIT.

Table 1. Iodine excess endemic goiter in coast, China (Data from Yu ZH, et al. [30])

| Year | Province | Rural areas | Water iodine (ug/l) | Urine iodine (ug/l) | Goiter crude incidence (%) |

Table 1. Iodine-containing compounds potentially associated with IIT

Radiological contrast agents: Diatrizoate, Iopanoic acid, Ipodate, Iothalamate, Metrizamide, Iopromide, Iopamidol, Iotrolan

Topical iodine preparation: Iodine tincture, povidone iodine (Betadine), Iodoform gaze

Solution: Saturated potassium iodide, Lugol solution, iodinated glycerol (organidin), echothiopate iodide, hydriodic acid syrup
Dietary iodine intake and the prevalence of papillary carcinoma (PTC)

Thyroid neoplasia can result from many different causes. These include low iodine diets, radioactive iodine and natural goitrogens. Dietary iodine intake act as a potential relevance risk factor of thyroid cancer [21,71-76]. Elevated incidence and mortality rate of thyroid cancer have been found in areas where iodine intake is high (Howaii, Iceland) [76-78]. In South India, among 300 patients with goiter with increased thyroid cancer risk. In epidemiology, in Sweden, the risk of thyroid cancer in females with cold nodules was 5.3% in the iodine sufficient area (mean UIIC 114 ug/l) and 2.7% in the iodine deficient area (mean UIIC < 50 ug/l) [86]. The highest incidence rates for thyroid cancer are Japan, where iodine intake is high [22]. Occult thyroid cancer (OTC) was more common in glands with nodular goiter (range 15.7%– 28.4%) in areas of excessive iodine intake [87-90]. A case-control study in Hawaiian adults reported the association between dietary iodine intake and thyroid cancer in 191 cases (85% PTC) and 442 controls [91]. But increasing thyroid cancer rates were not been associated with national iodine intake according to UIC data from US population [92,93], Sweden [94] and Denmark [95,96]. Overall, in the past 2 to 3 decades, there is clear temporal relationship in many countries between introduction of iodized salt and an increase in incidence of PTC [83,97-100] (Figure 5).

In case-control studies, cruciferous plants were found an association with increased thyroid cancer risk. In epidemiology, in Sweden, the risk of thyroid cancer associated with a high cruciferous vegetable intake was higher among female who had ever lived in an endemic goiter area [101]. In Poland, frequent cruciferous vegetable consumption was associated with a 1.5-fold increase in the risk of thyroid carcinoma [102]. However, A study from New Caledonia among Melanesian women who consume large quantities of cruciferous vegetables, and low iodine intake (< 96.0 ug/day) showed a positive association [103]. The study from Kuwait, high intake of cabbage showed an increased risk with a borderline significance [104]. Thus, in this area, more accumulated results are needed to be testable.

Overall, the findings indicated clearly carcinogenesis of 1131 or/ and radiogenic transformation on thyroid glands in the rats and man. Dietary iodine intake is another care of environmental relevance factor in thyroid diseases and papillary carcinoma.

Oncogenic thyroid hormone receptor mutants

It has been demonstrated that thyroid status had a modulating effect on neoplasia. Like iodine- induced hyperthyroidism and IIT, using thyroxine L-T4 which 65% of T4 weight is iodine, Ciosek [105] induced experimental model of rat hyperthyroidism. Administration of thyroid hormone to thyrectomized rodents is a prerequisite for the induction of hepatomas by chemicals, indicating a role in the initiating action of carcinogen [106]. This thyroid hormone (T3) signaling through matched controls, urinary excretion of iodine excess was detected in 302 cases of thyroid benign tumors (519 ug/L) and 240 thyroid cancers (524 ug/L) (Liu, 2008). Higher urine iodine was associated with PTC (urine iodine:355.3 +/- 289.6 ug/L In 53 PTC, Zhou, 2014).

And more, According to Zimmerann in recent review [12] and Williams the earlier review [22], there were reports that in countries with 'high' iodine intake (US, Iceland) the ratio of PTC: FTC ranged from 3.4 to 6.5, while in countries with 'moderate' iodine intake (the UK and northern Germany) the ratio was from 1.6 to 3.7, and in countries with 'low' iodide intake (Argentina, Columbia, Finland, Southern Germany, Austria and Switzerland) the ratio was from 0.19 to 1.7. The incidence of PTC in the Netherlands has increased by 2.1% per year between 1989 and 2003, which was partly explained by the stable and sufficient iodine intake of the Dutch population during the last 4 decades, together with other low level of radiation exposure and incidentally discovered thyroid nodules [84]. In northwestern Spain, iodized salt was introduced in 1985, the thyroid cancer incidence increased in females from 1.56/100,000 during 1978-1985 to 8.23/100,000 in period from 1984 to 2001, the PTC: FTC increased from 2.3 to 11.5 [85]. Italy had one of the highest incidence rates for thyroid cancer, nearly 20/100,000 women in 2007, the frequency of thyroid cancer in females with cold nodules was 5.3% in the iodine sufficient area (mean UIIC 114 ug/l) and 2.7% in the iodine deficient area (mean UIIC < 50 ug/l) [86]. The highest incidence rates for thyroid cancer are Japan, where iodine intake is high [22]. Occult thyroid cancer (OTC) was more common in glands with nodular goiter (range 15.7%– 28.4%) in areas of excessive iodine intake [87-90]. A case-control study in Hawaiian adults reported the association between dietary iodine intake and thyroid cancer in 191 cases (85% PTC) and 442 controls [91]. But increasing thyroid cancer rates were not been associated with national iodine intake according to UIC data from US population [92,93], Sweden [94] and Denmark [95,96]. Overall, in the past 2 to 3 decades, there is clear temporal relationship in many countries between introduction of iodized salt and an increase in incidence of PTC [83,97-100] (Figure 5).

In case-control studies, cruciferous plants were found an association with increased thyroid cancer risk. In epidemiology, in Sweden, the risk of thyroid cancer associated with a high cruciferous vegetable intake was higher among female who had ever lived in an endemic goiter area [101]. In Poland, frequent cruciferous vegetable consumption was associated with a 1.5-fold increase in the risk of thyroid carcinoma [102]. However, A study from New Caledonia among Melanesian women who consume large quantities of cruciferous vegetables, and low iodine intake (< 96.0 ug/day) showed a positive association [103]. The study from Kuwait, high intake of cabbage showed an increased risk with a borderline significance [104]. Thus, in this area, more accumulated results are needed to be testable.

Overall, the findings indicated clearly carcinogenesis of 1131 or/ and radiogenic transformation on thyroid glands in the rats and man. Dietary iodine intake is another care of environmental relevance factor in thyroid diseases and papillary carcinoma.

Oncogenic thyroid hormone receptor mutants

It has been demonstrated that thyroid status had a modulating effect on neoplasia. Like iodine- induced hyperthyroidism and IIT, using thyroxine L-T4 which 65% of T4 weight is iodine, Ciosek [105] induced experimental model of rat hyperthyroidism. Administration of thyroid hormone to thyrectomized rodents is a prerequisite for the induction of hepatomas by chemicals, indicating a role in the initiating action of carcinogen [106]. This thyroid hormone (T3) signaling through...
thyroid hormone receptor (THRa1) regulates hepatoma cell growth [107]. In literature, there have been more 10 cases of earlier reports on the thyroid carcinomas and concurrent hyperthyroidism (Grave’s disease), and also concurrent toxic nodular goiters [108-110]. The other 11 cases were further reported [111,112]. Among 10 hyperthyroidism, of whom 6 with Grave’s disease complicated with thyroid cancer, 2 hyperthyroidisms with thyroiditis and thyroid cancer [111]. Another case was reported in a 43-old-man with initial hyperthyroidism, and two years later transformation of thyroid adenoma complicated with hyperthyroidism (nodule6x4x3 cm), suggesting an initiating role of thyroxine on neoplasm and a wide variety of metabolic effects, for instance, increased lipogenesis and hair growth [112]. In addition, the transformation of culture cells by radiation is in vitro facilitated by thyroid hormone [113] (Figure 6).

In vivo, mice expressing THRAlpha1 specifically in the intestinal epithelium in wild-type THR alpha1 presented mucosal architecture and increased cell proliferation and develops adenoma at low rate [114], This phenotype is due to cooperation between the activated THRalpha1 and WNT pathways [115]. Mutation of thyroid hormone receptor-beta (THRbeta) in mice promotes the development of mammary hyperplasia via aberrant activation of STAT5 [116]. THRbeta mutants can also induce spontaneous development of follicular thyroid carcinoma (FTC) similar to human cancer in a knocking mouse model harboring a mutated THRbeta (Thrb, denoted PV) [117-119], and thyroid hormone play a critical role in promoting thyroid carcinogenesis of Thrb (PV/PV) mice via PI3K-AKT-beta-Catenin signaling pathway [120]. Moreover, southern analysis revealed a rearrangement of oncogenic THRA1/BTR fusion in the BT474 breast cancer cell line [121]. This rearrangement represented a deletion of THRA1 allele that was coamplified with ERBB2 in breast cancer. In clinics, almost 63% of 16 papillary thyroid carcinoma (PTC) were found to have mutations in THRalpha1, and a remarkable 94% in THRbeta1, in contrast 22% and 11% of thyroid adenomas harboring mutations in these isoforms respectively, and no mutations were found in normal thyroid controls, which implicate the differential effects of normal and oncogenic thyroid hormone receptor [122] signaling in PTC and normal health controls [123]. The findings suggest a possible oncogenic action for thyroid hormone receptor mutation in the tumorigenesis of human thyroid carcinoma [124]. Others, anaplastic thyroid cancers harbor novel oncogenic mutations of ALK gene [125]. Oncogenic receptor ALK belongs to an insulin receptor (IR) or oncogenic receptor IGF-1R family [126]. TLR4 stimulation with its ligand lipopolysaccharides promotes KSHV- induced cellular transformation and tumorigenesis by activating the STAT3 pathway [127]. Toll-like receptor (TLR4) induced pro-oncogenic function in head and neck carcinoma [128]. More others, CLIC1 was identified as a novel dominant pro-oncogenic receptor from proteomic profiling of pleomorphic human sarcoma [129]. Thus, an extensive study of thyroid hormone receptor (THR) mutations in oncogenic signaling, TSH/TSHR in thyroid disease and thyroid cancer, and also its target therapy [130,131] is further perspective.
