A generalization of the Heisenberg algebra has been recently constructed. This generalized algebra has a characteristic function which depends on one of its generators. When this function is linear, \( qJ_0 + s \), it is possible to construct a Generalized Quantum Field Theory (GQFT) that creates at a space-time a composite particle. In the present work we show that a generalized QFT can also be constructed consistently, even with a nonlinear characteristic function and leads to better results as long as we have more parameters to (possibly) fit the spectrum of a real composite particle.

I. INTRODUCTION

It is well known that the standard quantum field theory (QFT) is constructed within the framework of Heisenberg algebra \([1,2]\). Therefore a possible way to construct a non-standard QFT is through generalization of the Heisenberg algebra. A generalized Heisenberg algebra (GHA) has recently been proposed \([3]\). This generalized algebra has a characteristic function which depends on one of its generators. When this function is linear with slope \( q \), the algebra turns into a \( q \)-oscillator \([3]\) and it was shown \([4]\) that, for this case, it is possible to construct a generalized QFT that describes at a space-time a composite particle. In Ref \([4]\) the propagator, the first and second order scattering processes were computed and it was shown that the convergence of the perturbative series can be changed. However, other realizations of the GHA have been presented in \([3,5]\), the case where we have a nonlinear characteristic function. We will show, in this present work, that a self-consistent GQFT can also be constructed in that case and as a consequence we have more parameters to fit experimental data. A detailed discussion comparing these two case will be presented ahead.

The first step is to analyze the GHA for a general characteristic function \( f(J_0) \). As defined previously \([3]\), this generalized Heisenberg algebra is generated by three operators, \( J_0, A \) and \( A^\dagger \), and described by the following relations

\[
J_0 A^\dagger = A^\dagger f(J_0) \tag{1}
\]

\[
A J_0 = f(J_0) A \tag{2}
\]

\[
[A, A^\dagger] = f(J_0) - J_0 \tag{3}
\]

where \( ^\dagger \) means Hermitian conjugate and by hypothesis, \( J_0 \) is \( f(J_0) \) is an arbitrary function of \( J_0 \). Within this algebra we verify that the generators satisfy the Jacobi identity with

\[
C = A^\dagger A - J_0 = A A^\dagger - f(J_0) \tag{4}
\]

being the Casimir operator of the algebra. Assuming that there is a vacuum state represented by \( |0\rangle \), it can be demonstrated \([3]\) that for an arbitrary function \( f \), that

\[
J_0 |m - 1\rangle = f^{(m-1)}(a_0) |m - 1\rangle, \quad m = 1, 2 \tag{5}
\]

\[
A^\dagger |m - 1\rangle = N_{m-1} |m\rangle \tag{6}
\]

\[
A |m\rangle = N_{m-1} |m - 1\rangle, \tag{7}
\]

where \( N_{m-1} = f^m(a_0) - a_0 \), \( a_0 \) is the lowest \( J_0 \) eigenvalue and \( f^m(a_0) \) is the \( m \)th iteration through function \( f(a_0) \). This GHA describes a class of one-dimensional quantum systems characterized by energy eigenvalues given by

\[
e_n = f(e_{n-1}) \tag{8}
\]

where \( e_n \) and \( e_{n-1} \) are successive energy levels. Unlike standard Heisenberg Algebra (where the energy of the \( n \)-th level is equal to \( n \) times the energy of the first one), here, the energy of the \( n \)-th level (depending on the value of the parameters) is greater or smaller than \( n \) times the energy of the first one. In the last case, the energy gap between consecutive levels becomes smaller as \( n \) increases, behaving like the energy spectrum of a composite particle. So we can postulate that this algebra describes a composite particle.

II. A GENERALIZED QFT

Let us discuss, firstly, the algebra given by (1)-(3) for the quadratic case, i.e. \( f(J_0) = t J_0^2 + q J_0 + s \), which is the simplest nonlinear case. The algebraic relations (1)-(3) can be written as \([3]\]

\[
[J_0, A^\dagger]_q = t A^\dagger J_0^2 + s A^\dagger, \tag{9}
\]

\[
[J_0, A]_q = -\frac{t}{q} J_0^2 A - \frac{s}{q} A, \tag{10}
\]

\[
[A^\dagger, A] = t J_0^2 + (q - 1) J_0 + s, \tag{11}
\]
where $[a, b]_q = ab - q ba$, is the $q$-deformed commutation relation of two operators $a$ and $b$. The relations (9)-(11) describe a two-parameter deformed Heisenberg Algebra already studied [3]. Of course, for $t = 0$ we recover the linear case and if additionally $q = 1$, the standard Heisenberg algebra.

We focus now on the graphical analysis of the function $f(\alpha_0) = t\alpha_0^2 + q\alpha_0 + s$. Let us plot $y = f(\alpha_0)$ together with $y = \alpha_0$. In the points where lines intersect, we have $\alpha_0 = y = f(\alpha_0)$. So the intersections are precisely the fixed points.

Assuming $t < 0$, there are three cases to be analyzed: (a) $\Delta < 0$ (b) $\Delta = 0$ and (c) $\Delta > 0$, for $\Delta = (q-1)^2 + 4ts$ (see Fig 1). However, as depicted in (Fig. 1), depending on $t, q, s$ and $\alpha_0$, we have different spectra. Nevertheless, we are interested in a special spectrum which can be associated to a composite particle, thus, only the case (c) for $\alpha_{\text{min}} < \alpha_0 < \alpha_{\text{max}}$ is relevant. Fig 2 shows the comparison between the quadratic and the linear cases.

As one may notice, in the linear case, there is a simple relation among energy level gaps (as $n$ increases, the energy gap between successive levels always decreases) which make the linear case unsuitable to fit some realistic spectra, see for instance [11]. This makes the quadratic more suitable to fit the spectra of the mainstream composite particle.

\[ T = 1 + a \partial_p \]
\[ \bar{T} = 1 - a \bar{\partial}_p \] (12)
\[ \bar{T} T = T \bar{T} = 1. \] (16)

Introducing the momentum operator $P$
\[ P f(p) = pf(p), \] (17)
hence
\[ T P = (P + a) T \]
\[ \bar{T} P = (P - a) \bar{T}. \] (19)

Now, we will realize the operators $A^\dagger, A$ and $J_0$ in terms of physical operators, as in the case of the one-dimensional harmonic oscillator 1. In order to do so we will employ the formalism of non-commutative differential and integral calculus [6] which considers a one-dimensional lattice in a momentum space where the momenta are allowed to take only discrete values $p_0, p_0 + a, p_0 + 2a$, and so on, with $a > 0$. Let us introduce the momentum shift operator
\[ \bar{T} f(p) = f(p - a) \] (15)

FIG. 2. Comparison between the quadratic and linear cases

\[ T f(p) = f(p + a), \] (14)

and satisfy

Now, we return to the realization, observing that, in this case we have not an explicit formula for $f^{(n)}(\alpha_0)$ as

\[ 1 \text{ where } A^\dagger \text{ and } A \text{ can be written as a function of } p \text{ and } q. \]
in the linear one \([3]\), but we can still associate this two-parameter deformed Heisenberg algebra \((9)-(11)\) to the one-dimensional lattice we have just presented. By defining an operator \(N\) such that
\[
N|m\rangle = m|m\rangle,
\]
we can write an operator \(f(N,\alpha_0)\) that verifies
\[
f(N,\alpha_0)|m\rangle = f^m(\alpha_0)|m\rangle,
\]
So, using \((5)-(7)\) we can write \(J_0\) as
\[
J_0 \equiv f(N,\alpha_0) = \alpha_N = f(P/a,\alpha_0)
\]
where we have defined \(N = P/a\), with \(P\) given by \((17)\). This implies that
\[
P|m\rangle = ma|m\rangle, \quad m = 0, 1, 2, ...
\]
Moreover, it is easy to see \([4]\) that
\[
T|m\rangle = |m + 1\rangle, \quad m = 0, 1, 2, ...
\]
with \(T\) and \(T = T^\dagger\) defined in Eqs.\((14)-(15)\).

Now, using Eqs.\((5)-(7)\), we finally define
\[
A^\dagger = S(P) T, \quad A = T S(P),
\]
where
\[
S(P)^2 = J_0 - \alpha_0,
\]
being \(\alpha_0\) the lowest \(J_0\) eigenvalue. Following similar steps to those used to construct a standard spin-0 QFT \([7]\), let us define two operators
\[
\chi \equiv i(S(P) (1 - a \partial_p) - (1 + a \partial_p) S(P)) = -i(A - A^\dagger) \tag{28}
\]
\[
Q \equiv S(P) (1 - a \partial_p) + (1 + a \partial_p) S(P) = A + A^\dagger, \tag{29}
\]
satisfying
\[
[\chi, P] = -i a Q \tag{30}
\]
\[
[P, Q] = i a \chi \tag{31}
\]
\[
[\chi, Q] = 2 i(S^2(P) - S^2(P + a)). \tag{32}
\]

At this point, we introduce an independent copy of the one-dimensional momentum lattice, we have just defined, at each point of a \(K\)-lattice through the substitution \(P \rightarrow P_k\); so,
\[
A^\dagger_k = S_k T_k, \quad A_k = T_k S_k, \quad J_0(k) = \int \frac{d^2k}{2 \Omega} (\alpha_0).
\]
Then, we define three field operators
\[
\phi(\vec{r}, t) = \sum_k \frac{1}{\sqrt{2 \Omega \omega(k)}} (A^\dagger_k e^{-i \vec{k} \cdot \vec{r}} + A_k e^{i \vec{k} \cdot \vec{r}}), \tag{36}
\]
\[
\Pi(\vec{r}, t) = \sum_k \frac{\omega(k)}{2 \Omega} (A^\dagger_k e^{-i \vec{k} \cdot \vec{r}} - A_k e^{i \vec{k} \cdot \vec{r}}), \tag{37}
\]
\[
\phi(\vec{r}, t) = \sum_k \sqrt{\omega(k)} A_k e^{-i \vec{k} \cdot \vec{r}}, \tag{38}
\]
where \(\omega(k) = \sqrt{k^2 + m^2}\) and \(m\) is a real number. Using \((36)-(38)\) we can show that the Hamiltonian
\[
H = \frac{1}{2} \int d^3\vec{r}(\Pi^2(\vec{r}, t) + w(\vec{r}, t)\phi(\vec{r}, t))^2
\]
\[
+ \phi(\vec{r}, t) (-\nabla^2 + m^2) \phi(\vec{r}, t)
\]
can be written as
\[
H = \frac{1}{2} \sum_k w(\vec{k}) \left[ S^2_k (N + 1) + (1 + u)S^2_k(N) \right] \tag{40}
\]
where \(N^2_k = \tau \alpha_0^2 + (q - 1)\alpha_0 + 1\) and \(S^2(N)\) is given by Eq.\((27)\). Note that in the limit \(t \rightarrow 0\), we recover the linear case and for \(t \rightarrow 0\), \(q \rightarrow 1(u \rightarrow 0)\), the Hamiltonian is proportional to the number operator.

The time evolution of the fields can be studied by solving Heisenberg’s equation for \(A^\dagger_k, A_k\). So, using Eq. \((40)\) we have
\[
[H, A_k^\dagger] = w(\vec{k}) A_k^\dagger h(N_k) \tag{41}
\]
where for the quadratic case
\[
h(N_k) = \frac{1}{2} \Delta E \left[ t(S^2_k(N + 1) + S^2_k(N)) + 2 \tau \alpha_0 + Q \right], \tag{42}
\]
with \(Q = 1 + u + q\) and \(\Delta E = S^2_k(N + 1) - S^2_k(N)\). For the general case \(f(\alpha_0) = \sum_{j=0}^n a_j \alpha_0^j\), we have
\[
h(N_k) = \frac{1}{2} \Delta E \sum_{j=0}^n \sum_{l=0}^{n-1} \left[ a_j (S^2_k(N) + \alpha_0)^{j-l} \chi(N_k)^l \right] + (u + 1)
\]
with
\[
\chi(N) = \frac{S^2_k(N + 1) + \alpha_0}{S^2_k(N) + \alpha_0}. \tag{44}
\]
Solving the Heisenberg equation
\[
A^\dagger_k = A^\dagger_k(0) e^{t w(\vec{k}) h(N_k)t} \tag{45}
\]
we can write Eq.(36) as \( \phi(r', t) = \alpha(r', t) + \alpha^\dagger(r', t)^2 \) where

\[
\alpha^\dagger(r', t) = \sum_k \frac{1}{\sqrt{2 \Omega(w(k))}} A_k^\dagger e^{-i \mathbf{k} \cdot \mathbf{r}' + i w(k)} h(N_k) t.
\]

(46)

The Feynman propagator \( D_F^N(x_1, x_2) \) defined as Dyson-Wick contraction between \( (r_i, t_i) \) and \( \phi(x_1) \) and \( \phi(x_2) \) can be computed using (46). In the integral representation it is given by

\[
D_F^N(x) = \frac{-i}{(2\pi)^4} \int d^4 k \frac{S_k^2(N + 1) e^{-i \mathbf{k} \cdot \mathbf{r} + i w(N_k) t}}{k^2 + m^2} + (N \rightarrow N - 1).
\]

(47)

Note that, if \( q \rightarrow 1 \) the standard result is recovered.

III. PERTURBATIVE COMPUTATION

We shall now analyze the scattering process \( 1 + 2 \rightarrow 1' + 2' \) for \( \mathbf{p}_1 \neq \mathbf{p}_2 \neq \mathbf{p}_{1}' \neq \mathbf{p}_{2}' \) with initial state

\[
N_0^2 |1, 2\rangle = A_{p_1}^\dagger A_{p_2}^\dagger |0\rangle
\]

(48)

and final state

\[
N_0^2 |1, 2\rangle = A_{p_1}^\dagger A_{p_2}^\dagger |0\rangle
\]

(49)

where these particles are described by the Hamiltonian given in Eq.(40) with an interaction \( \lambda \int : \phi^4(r', t) : d^3 r' \).

For the first order scattering process we have

\[
S_{f_1} = \frac{N_0^4 \lambda^2 \delta^4(P_1 + P_2 - P_{1}' - P_{2}') I}{\Omega^2 (t (N_0^2 + 2\alpha) + Q)} \sqrt{\omega_{p_1} \omega_{p_2} \omega_{p_{1}'} \omega_{p_{2}'}},
\]

(50)

and for the second order

\[
S_{f_2} = \frac{N_0^4 \lambda^2 \delta^4(P_1 + P_2 - P_{1}' - P_{2}') I}{2\Omega^2 (t (N_0^2 + 2\alpha) + Q)} \sqrt{\omega_{p_1} \omega_{p_2} \omega_{p_{1}'} \omega_{p_{2}'}},
\]

(51)

\[
S_{f_2} = \frac{N_0^4 \lambda^2 \delta^4(P_1 + P_2 - P_{1}' - P_{2}') I'}{2\Omega^2 (t (N_0^2 + 2\alpha) + Q)} \sqrt{\omega_{p_1} \omega_{p_2} \omega_{p_{1}'} \omega_{p_{2}'}},
\]

(52)

\[
S_{f_2} = \frac{N_0^4 \lambda^2 \delta^4(P_1 + P_2 - P_{1}' - P_{2}') I''}{2\Omega^2 (t (N_0^2 + 2\alpha) + Q)} \sqrt{\omega_{p_1} \omega_{p_2} \omega_{p_{1}'} \omega_{p_{2}'}},
\]

(53)

\[
S_{f_2} = \frac{N_0^4 \lambda^2 \delta^4(P_1 + P_2 - P_{1}' - P_{2}') I'''}{2\Omega^2 (t (N_0^2 + 2\alpha) + Q)} \sqrt{\omega_{p_1} \omega_{p_2} \omega_{p_{1}'} \omega_{p_{2}'}},
\]

(54)

where,

\[
P_i = (\tilde{p}_i, \omega_{\tilde{p}_i}),
\]

(55)

\[
P_i' = (\tilde{p}_i', \omega_{\tilde{p}_i'}),
\]

(56)

\[
I = \int d^4 k \frac{1}{(k^2 + m^2)((-k + s)^2 + m^2)},
\]

(57)

with \( s = P_1 + P_2 \), and

\[
I' = I(s \rightarrow -s),
\]

(59)

\[
I'' = I(s \rightarrow t),
\]

(60)

\[
I''' = I(s \rightarrow u),
\]

(61)

being

\[
t = P_1 - P_2, \quad u = P_1 - P_2.
\]

(62)

(63)

So, up to second order we have

\[
S_{f_1} = \frac{\lambda N_0^2}{(N_0^2 + 2\alpha)} A_1^A + \frac{\lambda^2 N_0^4}{((N_0^2 + 2\alpha) + Q)^2} (A_2' + A_2'' + A_2''')
\]

(64)

where \( A_1, A_2, A_2' \) and \( A_2'' \) are the same contributions that one can find in the structureless particle standard \( \lambda-\phi^4 \) theory model corresponding to the \( s, t \) and \( u \) channels for \( \phi \).
Fig. 3 compares the deformed cross section, for the linear and quadratic cases, with the standard one [9]. As one can see, the linear case always gives a deformed-cross section smaller than the standard one for $0 < \alpha_0 < \epsilon^*$ and greater for $\alpha_0 < 0$ (for $0 < q < 1$). Therefore, it becomes difficult to fit both energy spectrum of the composite particle and cross section, inasmuch as we may have an ambiguous situation where we need $\alpha_0 < 0$ to fit the energy spectrum and $\alpha_0 > 0$ for the cross section. However, in the quadratic case we do not have such ambiguity (as depicted in Fig. 3) because we have one more parameter.

**IV. CONCLUSION**

We showed that within the framework of deformed Heisenberg algebra, with a quadratic characteristic function, it is possible to construct a generalized quantum field theory (GQFT) that describes a composite particle. Comparison between a GQFT made with a linear [4] and quadratic characteristic function was performed showing that, the latter, is more suitable to fit experimental data. It is worthwhile to mention that a GQFT made with a general characteristic function brings wider possibilities than the quadratic one but several restrictions must be imposed to the parameters, $a_1, a_2, ..., a_N$, in order to describe a composite particle. These restrictions are already present in the quadratic case but the algebra is much more simple for this case. One can show that the general case can be obtained replacing $Q \rightarrow \sum_{j=1}^{n} \sum_{i=0}^{j-1} \left[ a_j (\alpha_0)^{-1} \right] + (u + 1)$. In future works we will address this formalism to analyze Compton scattering by nuclei below pion threshold where no quantitative consistent description exists based on first principles [10].
