THE UNIFYING DOUBLE COMPLEX ON SUPERMANIFOLDS

SERGIO L. CACCIATORI, SIMONE NOJA, AND RICCARDO RE

Abstract. We unify the notions of differential and integral forms on real, complex and algebraic supermanifolds. We do this by constructing a double complex resulting from a triple tensor product of sheaves, whose associated spectral sequences give the de Rham complex of differential forms and the Spencer complex of integral forms at page one. For real and complex supermanifolds both the spectral sequences converge at page two to the locally constant sheaf. We use this fact to show that the cohomology of differential forms is isomorphic to the cohomology of integral forms, and they both compute the de Rham cohomology of the reduced manifold. Furthermore, we show that, in contrast with the case of ordinary complex manifolds, the Hodge-to-de Rham (or Frölicher) spectral sequence of supermanifolds with Kähler reduced manifold does not converge in general at page one.

1. Introduction

In the geometry of differential, complex analytic or algebraic supermanifolds the notion of integral forms has been developed for the purpose of defining an integration theory analogous to the ordinary integration of differential forms on (sub)manifolds in the classical setting. In this view, in the context of supergeometry, integral forms appear as more useful and natural mathematical objects than differential forms. However, on the other hand, the definition of sheaves of differential forms, vector fields or also sheaves of linear differential operators is easily available in supergeometry by the same constructions as in classical geometry - consider for example the construction of these objects by Grothendieck, which applies to an extremely general setting. One purpose of this paper is to give a new construction of integral forms which is both coordinate-free and built upon the more standard notions of differential forms and operators, with the future aim of studying possible generalizations of these to other classes of “superforms”.

We stress that the syntax of such objects is known in the physics literature: this means that there exists a formalism of integral forms expressed in terms of coordinates, together with associated calculus and transformation rules [16, 18]. This formalism has been further expanded to an extended formalism of “superforms”, generalization of integral forms, which have been developed and applied, for example, in the recent [2, 3, 4, 5, 8, 7]. On the semantic side, of course a coordinate-free construction of integral forms exists in the supergeometry literature, see [11], but in a way which is unrelated to differential forms, so that there is no obvious relations between these two concepts.

In the present paper, starting from first principles, we unify the notions of differential and integral forms and their related complexes on real, complex and also algebraic supermanifolds. In particular, given the natural sheaves of differential operators $\mathcal{D}_\mathbb{M}$ and differential forms $\Omega^*_{\mathbb{M}, \text{odd}}$ on a certain supermanifold $\mathbb{M}$, we start from the so-called universal de Rham complex $\Omega^*_{\mathbb{M}, \text{odd}} \otimes_{\mathcal{O}_\mathbb{M}} \mathcal{D}_\mathbb{M}$ and universal Spencer complex $\mathcal{D}_\mathbb{M} \otimes_{\mathcal{O}_\mathbb{M}} (\Omega^*_{\mathbb{M}, \text{odd}})^*$ and we show that they can be unified into a single
double complex of sheaves supported on the triple tensor product $\Omega^\bullet_{M, \text{odd}} \otimes_{\mathcal{O}_M} D_M \otimes_{\mathcal{O}_M} (\Omega^\bullet_{M, \text{odd}})^*$, that displays a truly non-commutative behavior - rather than just a super-commutative one - due to the sheaf $D_M$ in the pivotal position. The two spectral sequences associated to this double complex yield, at page one, the complex of differential forms and the complex of integral forms on $M$. Furthermore, in the case of real or complex supermanifolds, both spectral sequences converge at page two to the sheaf of locally constant functions over $\mathbb{R}$ or $\mathbb{C}$, depending on the supermanifold being real or complex. This is a consequence of the Poincaré lemma for differential and integral forms. Whilst the proof of the Poincaré lemma for differential forms in a supergeometric context is well-known and it consists of a straightforward generalization of the ordinary one, the Poincaré lemma for integral forms, instead, is a hallmark of supergeometry: we thus prove it in details, filling a gap in the literature. Finally, we enhance the above double complex of sheaves with a triple complex structure, by taking its Čech cochains. In this way one obtains two double complexes: one is the Čech-de Rham double complex of differential forms on $M$ and the other is the Čech-Spencer double complex of integral forms on $M$. We show that they both converge to the de Rham cohomology of the reduced manifold, proving the equivalence of the cohomology of differential and integral forms. Nonetheless, in the case of a complex supermanifold with Kähler reduced manifold something intriguing happens. Indeed, the Hodge-to-de Rham (or Frölicher) spectral sequence, which still computes the de Rham cohomology of the reduced manifold, does not converge at page one, as it does in the ordinary setting. Instead, there are many more non-trivial maps, thus hinting at new exciting developments in the geometry of complex supermanifolds.

Acknowledgments. The authors wish to thank Ivan Penkov for fruitful discussions and advice.

2. Setting the Stage: Main Definitions

In the following we will work over a real, complex analytic or algebraic supermanifold $M$ unless otherwise stated, see the classical textbook [11] for a thorough introduction, or the recent [6] by the authors for a short compendium to the topic.

We let $M$ be a supermanifold of dimension $p|q$ and we denote its reduced space by $M_{\text{red}}$, which is an ordinary (real, complex or algebraic) manifold of dimension $p$. In particular, we will deal with the sheaf of 1-forms $\Omega^1_{M, \text{odd}}$ on $M$. This is a locally-free sheaf on $M$ of rank $q|p$. Indeed, if we let $U$ be an open set in the topological space underlying $M_{\text{red}}$ and we set $x_a = z_i \theta \eta$ for $i = 1, \ldots, p$ and $\alpha = 1, \ldots, q$ to be a system of local coordinates over $U$ for the supermanifold $M$, we have that

$$\Omega^1_{M, \text{odd}}(U) = \{d\theta_1, \ldots, d\theta_q, dz_1, \ldots, dz_p\} \cdot \mathcal{O}_M(U), \quad (2.1)$$

where $\mathcal{O}_M$ is the structure sheaf of $M$ and we stress that the $d\theta$’s are even and the $dz$’s are odd, as we take the differential $d: \mathcal{O}_M \to \Omega^1_{M, \text{odd}}$ to be an odd morphism. Also, note that we have written $\Omega^1_{M, \text{odd}}$ as a locally-free sheaf of right $\mathcal{O}_M$-modules.

Likewise, we denote the dual of $\Omega^1_{M, \text{odd}}$ with $(\Omega^1_{M, \text{odd}})^*$: clearly, this can be canonically identified with the sheaf $\Pi \mathcal{T}_M$, where $\mathcal{T}_M$ is the tangent sheaf of $M$ and $\Pi$ - the so-called parity-changing functor - is there to remind that the parity of the sheaf is reversed, so that the rank of $\Pi \mathcal{T}_M$ is actually $q|p$. We will call a section of $\Pi \mathcal{T}_M = (\Omega^1_{M, \text{odd}})^*$ a $\Pi$-vector field or vector field for short. Locally, $(\Omega^1_{M, \text{odd}})^*$ is generated by expressions of the kind

$$(\Omega^1_{M, \text{odd}})^*(U) = \mathcal{O}_M(U) \cdot \{\pi \partial \theta_1, \ldots, \pi \partial \theta_q, \pi \partial z_1, \ldots, \pi \partial z_p\}, \quad (2.2)$$

where the $\pi \partial \theta$’s are even and the $\pi \partial z$’s are odd. Notice that $(\Omega^1_{M, \text{odd}})^*$ has been written with the structure of locally-free sheaf of left $\mathcal{O}_M$-modules.

Applying the supersymmetric power functor $S^\bullet$ to the sheaf $\Omega^1_{M, \text{odd}}$ and $(\Omega^1_{M, \text{odd}})^*$ one gets the usual notion of (differentially graded) algebra of forms and polyfields over a supermanifold. In particular, we call a section of the sheaf $\Omega^k_{M, \text{odd}} := S^k \Omega^1_{M, \text{odd}}$ a differential $k$-superform, or a $k$-form for short. The differential $d: \mathcal{O}_M \to \Omega^1_{M, \text{odd}}$ lifts to the exterior derivative $d: \Omega^k_{M, \text{odd}} \to \Omega^{k+1}_{M, \text{odd}}$, which is an odd (nilpotent) superderivation of $\Omega^\bullet_{M, \text{odd}}$ obeying the Leibniz rule in the form

$$d(\omega \eta) = d\omega \eta + (-1)^{|\omega|} \omega d\eta, \quad (2.3)$$

where $|\omega|$ and $|\eta|$ are the parities of the forms $\omega$ and $\eta$, respectively.
where we have left the product in the superalgebra of forms understood, for \( \omega \in \Omega^k_M, odd \) and \( \eta \in \Omega^\eta_M, odd \) and where \( |\omega| \) is the parity of \( \omega \) (which equals the degree of \( \omega \mod \mathbb{Z}/2 \)). Notice that \((-1)^{|\omega|} = (-1)^{\text{deg}(\omega)}\). The pair \((\Omega^\bullet_M, odd, d)\) defines the de Rham complex of \( \mathcal{M} \). Once again, we will consider any \( \Omega^\bullet_M, odd \) with the structure of right \( \mathcal{O}_\mathcal{M} \)-module.

Likewise, we call a section of \((\Omega^k_M, odd)^* = S^k \Pi^\mathcal{M} \) a \( k \)-vector \( k \)-field, or a polyvector field for short. Once again, any \((\Omega^k_M, odd)^*\) has the structure of left \( \mathcal{O}_\mathcal{M} \)-module.

Notice that there exists a pairing

\[
\langle \omega, \tau \rangle : \Omega^\bullet_M, odd \otimes \mathcal{O}_\mathcal{M} (\Omega^\bullet_M, odd)^* \to \Omega^\bullet_M, odd \to \langle \omega, \tau \rangle
\]

which is defined via the contractions in such a way that

\[
\langle dx_a, \pi \partial_{x_a} \rangle = (-1)^{|x_a|+1}(|x_a|+1) \delta_{ab}.
\]

In particular, it can be observed that 1-forms \( \omega \in \Omega^1_M, odd \) act as superderivations of \((\Omega^\bullet_M, odd)^*\), i.e. they satisfy the Leibniz rule in the above form. Moreover, explicitly, for \( \pi X \in \Pi^\mathcal{M} \) and \( \omega = df \in \Omega^1_M, odd \) one easily finds that

\[
\langle df, \pi X \rangle = (-1)^{|(f|+1)X(f)}.
\]

where \( f \in \mathcal{O}_\mathcal{M} \) and \( X \in \mathcal{T}^\mathcal{M} \).

Also, we introduce the sheaf \( \mathcal{D}_\mathcal{M} \) of (linear) differential operators on \( \mathcal{M} \), which can be abstractly defined as the subalgebra of \( \mathcal{E}nd_k(\mathcal{O}_\mathcal{M}) \) that is generated by \( \mathcal{O}_\mathcal{M} \) and \( \mathcal{T}^\mathcal{M} \). This means that over an open set \( U \) one has that the set \([x_a, \partial_{x_a}]\), where \( x_a \in \mathcal{O}_\mathcal{M}[U] \) and \( \partial_{x_a} \in \mathcal{T}^\mathcal{M}[U] \) for \( a \) ranging over both even and odd coordinates, gives a local trivialization of \( \mathcal{D}_\mathcal{M} \) over \( U \) and where the following defining relations are satisfied

\[
[x_a, x_b] = 0, \quad [\partial_{x_a}, \partial_{x_b}] = 0, \quad [\partial_{x_a}, x_b] = \delta_{ab},
\]

with \([, , ]\) being the supercommutator. It follows that \( \mathcal{D}_\mathcal{M}[U] \) is isomorphic to the Weyl superalgebra of \( \mathbb{K}^{p\mid q} \): the sheaf \( \mathcal{D}_\mathcal{M} \) is thus noncommutative better than just supercommutative, something which will play a major role in what follows. It is also worth stressing that \( \mathcal{D}_\mathcal{M} \) admits a filtration by the degree of the differential operators such that \( \mathcal{D}_\mathcal{M}^{(\leq i)} \subseteq \mathcal{D}_\mathcal{M}^{(\leq i+1)} \) for any \( i \geq 0 \) and \( \mathcal{D}_\mathcal{M}^{(\leq i)} \cdot \mathcal{D}_\mathcal{M}^{(\leq j)} \subseteq \mathcal{D}_\mathcal{M}^{(\leq i+j)} \). It is not hard to see that, defining \( \text{gr}^k(\mathcal{D}_\mathcal{M}) := \mathcal{D}(\leq k)/\mathcal{D}(\leq k-1) \), one has \( \text{gr}^k(\mathcal{D}_\mathcal{M}) \cong S^k \mathcal{T}_\mathcal{M} \), so that one has \( \text{gr}^k \mathcal{D}_\mathcal{M} \cong S^k \mathcal{T}_\mathcal{M} \), which can be looked at as a sort of supercommutative approximation of \( \mathcal{D}_\mathcal{M} \). Finally, notice that \( \mathcal{D}_\mathcal{M} \) is endowed with the structure of super-module, i.e. \( \mathcal{D}_\mathcal{M} \) is a left and right \( \mathcal{O}_\mathcal{M} \)-module with the operations given respectively by multiplications to the left and to the right by elements \( f \in \mathcal{O}_\mathcal{M} \).

A construction which is peculiar of supergeometry is the one of Berezinian sheaf of a supermanifold. This substitutes the notion of canonical sheaf on an ordinary manifold, which makes no sense on a supermanifold since the de Rham complex is not bounded from above. Notice that this sheaf does not belong to the de Rham complex, i.e. it is not made out of ordinary differential forms in \( \Omega^1_M, odd \). Instead, just like the canonical sheaf in a purely commutative setting, the Berezinian sheaf can be defined via the Koszul complex, or better its supersymmetric generalization \([11, 14]\), see also the very nice construction in \([13]\). More precisely, given a locally-free sheaf \( \mathcal{E} \) of rank \( p \mid q \) over a supermanifold \( \mathcal{M} \), one defines the Berezinian sheaf \( \text{Ber}(\mathcal{E}) \) of \( \mathcal{E} \) to be the locally-free sheaf of rank \( \delta_{0, (p+q) \mod 2} \cdot \delta_{1, (p+q) \mod 2} \) given by \( \text{Ber}(\mathcal{E}) := \mathcal{E} \otimes_{S^p \mathcal{T}_\mathcal{M}} (\mathcal{O}_\mathcal{M}, S^q \mathcal{T}_\mathcal{M}) \). In particular, one defines the Berezinian sheaf of the supermanifold \( \mathcal{M} \) to be \( \text{Ber}(\mathcal{M}) := \text{Ber}(\Omega^\bullet_M, odd)^* \), i.e. one has

\[
\text{Ber}(\mathcal{M}) := \text{Hom}_{\mathcal{O}_\mathcal{M}}(\mathcal{E} \otimes_{S^p \mathcal{T}_\mathcal{M}} (\mathcal{O}_\mathcal{M}, S^q \mathcal{T}_\mathcal{M}), \mathcal{O}_\mathcal{M}) \cong_{\text{loc}} \Theta^p \mathcal{T}_\mathcal{M} \mathcal{O}_\mathcal{M}
\]

In the following, we will use extensively that if \( x = z_1, \ldots, z_p | \theta_1, \ldots, \theta_q \) is a system of local coordinates for \( \mathcal{M} \), then the Berezinian sheaf is locally-generated by the class

\[
\phi(x) = [dz_1 \ldots dz_p \otimes \partial_{\theta_1} \ldots \partial_{\theta_q}]
\]

in the homology above. In what follows the Berezinian sheaf will be looked at as a sheaf or right \( \mathcal{O}_\mathcal{M} \)-modules.
The Berezinian sheaf of \( M \) enters the construction of the so-called integral forms, see for e.g. \([11]\) or \([12]\). Given a supermanifold \( M \), these are defined as sections of the sheaf \( \text{Hom}_{\mathcal{O}_M}(\Omega^*_{M,odd}, \text{Ber}(M)) \), or analogously \( \text{Ber}(M) \otimes_{\mathcal{O}_M} S^* \Pi TM \). Integral forms can be endowed with the structure of an actual complex by providing a differential \( \delta : \text{Ber}(M) \otimes_{\mathcal{O}_M} S^k \Pi TM \to \text{Ber}(M) \otimes_{\mathcal{O}_M} S^{k-1} \Pi TM \), whose definition is quite tricky (well-definedness and invariance are far from obvious), see for example \([11]\), where the differential on integral forms is induced using the notion of right connection on \( \text{Ber}(M) \). For this reason the differential making integral forms into an actual complex will be discussed further later on in the paper. Here we limit ourselves to say that, locally, moving functions to the left of the tensor product \( \text{Ber}(M) \otimes_{\mathcal{O}_M} S^k \Pi TM \), the differential gets written as

\[
\delta(\varphi(x) f \otimes \pi \partial^J) = - \sum_a (-1)^{|x_a| + |\pi \partial^J|} \varphi(x)(\partial_a f) \otimes \partial_\pi \partial_a (\pi \partial^J)
\]  

(2.9)

where \( \varphi(x) \) is the local generating section of \( \text{Ber}(M) \) introduced above, \( \pi \partial^J \) is a homogeneous section of \( S^k \Pi TM \), \( f \) is a function and where the derivative with respect to the coordinate field \( \pi \partial_a \) is nothing but the contraction of the polyfield with the form dual to \( \pi \partial_a \), that is \( (dx_a, \pi \partial^J) = \partial_a \partial_\pi (\pi \partial^J) \). We will see that this definition is related with the structure of right \( D_M \)-module of \( \text{Ber}(M) \) - first discovered by Penkov in \([12]\) - and, in turn, with its Lie derivative. Finally, we stress that given a \( \mathbb{P} \mathbb{Q} \) dimensional supermanifold \( M \), it is useful to shift the degree of the complex of integral forms, posing \( \Omega^p_{M,odd} := \text{Ber}(M) \otimes_{\mathcal{O}_M} S^{p-\bullet} \Pi TM \) and consider \((\Omega^p_{M,odd}, \delta)\), so that an integral form of degree \( p \), i.e. a section of the Berezinian sheaf, can be integrated on \( M \), exactly as an ordinary \( p \)-form can be integrated on an ordinary \( p \)-dimensional manifold. More in general, with this convention, it can be seen that an integral form on \( M \) of degree \( p - k \) can be integrated on a sub-supermanifold of \( M \) of codimension \( k \neq 0 \) in \( M \), see for example \([16]\).

3. Universal de Rham Complex and its Homology

We now introduce one of the main characters of our study.

**Definition 3.1** (Universal de Rham Sheaf of \( M \)). Given a supermanifold \( M \), we call the sheaf \( \Omega^*_{M,odd} \otimes_{\mathcal{O}_M} D_M \) the universal de Rham sheaf of \( M \).

Notice that the universal de Rham sheaf is \( \mathbb{Z} \)-graded by the gradation of \( \Omega^*_{M,odd} \) and also \( \mathbb{Z}_2 \)-graded as both of its components are. Moreover it is filtered by the filtration by degree on \( D_M \) introduced in the previous section. Clearly, the universal de Rham sheaf \( \Omega^*_{M,odd} \otimes_{\mathcal{O}_M} D_M \) is naturally a left \( \Omega^*_{M,odd} \)-module and a right \( D_M \)-module. In particular it is a left \( \mathcal{O}_M \)-module by restriction on the structure of \( \Omega^*_{M,odd} \)-module. On the other hand \( \Omega^*_{M,odd} \otimes D_M \) is also a right \( \mathcal{O}_M \)-module with the structure induced by the one of right \( D_M \)-module: this structure, though, does not coincide with the one of left \( \mathcal{O}_M \)-module.

We are interested into finding a natural differential as to make the universal de Rham sheaf into a proper complex of sheaves. We first need the following

**Definition 3.2** (\( \mathcal{O}_M \)-Definition). Let \( L \) and \( R \) be a left and a right \( \mathcal{O}_M \)-module respectively. Let \( \phi : \mathcal{R} \otimes \mathcal{L} \to \mathcal{H} \) be a morphism of sheaves of \( \mathcal{C} \)-modules into a sheaf \( \mathcal{H} \). We say that \( \phi \) is \( \mathcal{O}_M \)-defined if it descends to a \( \mathbb{C} \)-linear operator \( \hat{\phi} : \mathcal{R} \otimes_{\mathcal{O}_M} \mathcal{L} \to \mathcal{H} \), i.e. if the identity

\[
\phi((l \otimes r) = \phi(l \otimes fr)
\]

(3.1)

holds true for any \( l \in \mathcal{L}, r \in \mathcal{R} \) and \( f \in \mathcal{O}_M \).

Given this definition, we now introduce the following operator

**Definition 3.3** (The Operator \( D \)). For \( \omega \otimes F \in \Omega^*_{M,odd} \otimes_{\mathcal{O}_M} D_M \) such that \( \omega \) and \( F \) are homogeneous, we let \( D \) be the operator

\[
D : \Omega^*_{M,odd} \otimes D_M \rightarrow \Omega^*_{M,odd} \otimes_{\mathcal{O}_M} D_M
\]

\[
\omega \otimes F \mapsto D(\omega \otimes F) := d\omega \otimes F + \sum_a (-1)^{|\omega| |x_a|} dx_a \omega \otimes \partial_x a \cdot F,
\]

where \( x_a = z_1, \ldots, z_p | \theta_1, \ldots, \theta_q \), so that the index \( a \) runs over all of the even and odd coordinates.
Clearly, the operator $D$ is of degree $+1$ with respect to the $Z$-degree of $\Omega^*_M,\text{odd}$, i.e. it raises the form number by one. The properties of the operator $D$ are characterized in the following Lemma

**Lemma 3.4.** The operator $D$ has the following properties:

1. It is globally well-defined, i.e. it is invariant under generic change of coordinates;
2. It is $O_M$-defined, i.e. it induces an operator $D : \Omega^*_M,\text{odd} \otimes_{O_M} D_M \otimes_{O_M} (\Omega^*_M)^* \rightarrow \Omega^*_M,\text{odd} \otimes_{O_M} D_M \otimes_{O_M} (\Omega^*_M)^*$;
3. It is nilpotent, i.e. $D^2 = 0$.

**Proof.** We prove separately the various points of the Lemma.

1. Obvious, since each of the two summands is invariant by itself.
2. We prove that for any $f \in O_M$, $\omega \in \Omega^*_M,\text{odd}$ $F \in D_M$ we have $D(\omega f \otimes \omega F) = D(\omega \otimes f F)$.

   Indeed, posing $df = \sum_a dx_a \partial_{x_a} f$, on the one hand one computes
   
   \[
   D(\omega f \otimes F) = (d\omega)f \otimes F + (-1)^{\omega}(df) \otimes F + \sum_a (-1)^{|x_a|(|\omega|+|f|)} dx_a \omega f \otimes \partial_{x_a} F
   \]
   
   On the other hand, one has
   
   \[
   D(\omega f \otimes f F) = d\omega \otimes f F + \sum_a (-1)^{|x_a|(|\omega|+|f|)} dx_a \omega \otimes \left((\partial_{x_a} f)F + (-1)^{|x_a|} f(\partial_{x_a} F)\right)
   \]
   
   so that (3.3) is matched by (3.4).

3. We prove that $D^2 = 0$. Writing $D = D_1 + D_2$, with $D_1 := d \otimes 1$ and $D_2 := \sum_a dx_a \otimes \partial_{x_a}$ one has that $D^2 = D_1^2 + (D_1 D_2 + D_2 D_1) + D_2^2$. Clearly, $D_1^2 = 0$ and $D_2^2 = 0$ as well, for it is an odd element in the supercommutative algebra $\mathbb{C}[dx_a] \otimes_{\mathbb{C}} \mathbb{C}[\partial_{x_a}]$. It remains to prove that

   \[
   [D_1, D_2] := D_1 D_2 + D_2 D_1 = 0.
   \]

   We have
   
   \[
   D_2 D_1(\omega \otimes F) = \sum_a (-1)^{|x_a|(|\omega|+|1|)} dx_a d\omega \otimes \partial_{x_a} F. \tag{3.5}
   \]

   One the other hand, one finds
   
   \[
   D_1 D_2(\omega \otimes F) = \sum_a (-1)^{|x_a|(|\omega|+|1|)+1} dx_a d\omega \otimes \partial_{x_a} F \tag{3.6}
   \]

   which cancels exactly with the previous expression for $D_2 D_1$.

The above Lemma justifies the following definition.

**Definition 3.5 (Universal de Rham Complex of $M$).** Let $M$ be a supermanifold. We call the pair $(\Omega^*_M,\text{odd} \otimes_{O_M} D_M, D)$ the universal de Rham complex of $M$.

We now compute the homology of this complex.

**Theorem 3.6 (Homology of the Universal de Rham Complex).** Let $M$ be a supermanifold and let $(\Omega^*_M,\text{odd} \otimes_{O_M} D_M, D)$ be the universal de Rham complex of $M$. There exists a canonical isomorphism

\[
H_*((\Omega^*_M,\text{odd} \otimes_{O_M} D_M, D)) \cong \text{Ber}(M), \tag{3.7}
\]

where $\text{Ber}(M)$ is the Berezinian sheaf of $M$.

**Proof.** The proof can be done by constructing a homotopy for the operator $D$. Clearly, the first part of $D$, namely $D_1 = d \otimes 1$ has the usual homotopy of the de Rham complex. By the way elements of the form $c \otimes F$, for $c$ a constant and $F$ a generic element in $D_M$ are not in the kernel of $D$.

Let us now look at the second summand, $D_2(\omega \otimes F) = \sum_a (-1)^{|x_a|} dx_a \omega \otimes \partial_{x_a} F$. Working in a chart $(U, x_a)$ such that the sheaf $\Omega^*_M,\text{odd} \otimes_{O_M} D_M$ can be represented as the sheaf of vector spaces
generated by the monomials of the form $\omega \otimes F$ with $\omega = dx^I$, $F = \partial^J f$ for some multi-indices $I$ and $J$ and some $f \in \mathcal{O}_M(U)$, we define the following operator on $\Omega^r_{M,odd} \otimes D_M(U)$

$$H(\omega \otimes F) := \sum_a (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} dx^I \otimes [\partial^J, x_a] f. \quad (3.8)$$

where the derivation $\partial_{dx_a}$ can be seen as the contraction with respect to the coordinate field $\partial_a$ (up to a sign). We claim that $H$ is a homotopy. Computing one gets:

$$D_2 H(\omega \otimes F) = \sum_{a,b} (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} \partial_{dx_b} \omega \otimes \partial_a [\partial^J, x_b] f,$$  

$$H D_2 (\omega \otimes F) = \sum_{a,b} (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} (\partial_{dx_b} \omega) \otimes [\partial_b \partial^J, x_a] f. \quad (3.9)$$

Expanding the above expression, one finds

$$H D_2 (\omega \otimes F) = -D_2 H(\omega \otimes F) + \sum_{a,b} (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} \omega \otimes \partial_a [\partial^J, x_b] f + \sum_{a} (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} (\partial_{dx_a} \omega) \otimes \partial^J f. \quad (3.10)$$

We now analyze the various pieces of the above expression. If $x_a = z_1, \ldots, z_p | \theta_1, \ldots, \theta_q$, recalling that $\omega = dx^I$, we define $\deg_0(\omega)$ to be the degree of $\omega$ with respect to the even generators ($d\theta$'s) and $\deg_1(\omega)$ to be the degree of $\omega$ with respect to the odd generators ($d\theta$'s) and likewise we pose $\deg_0(\partial^J)$ to be the degree of $\partial^J$ with respect to the even generators ($\partial_\theta$'s) and $\deg_1(\partial^J)$ to be the degree of $\partial^J$ with respect to the odd generators ($\partial_\theta$'s). With these definitions, one can observe that

$$\sum_{a,b} (1)^{\deg_x(3+|\partial^J|+1)} \delta_{ab} \omega \otimes \partial^J f = (p+q)(\omega \otimes F),$$

$$\sum_{a} (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} \omega \otimes \partial_a [\partial^J, x_b] f = (\deg_0(\partial^J) - \deg_1(\partial^J))(\omega \otimes F),$$

$$\sum_{a} (1)^{\deg_x(3+|\partial^J|+1)} \partial_{dx_a} (\partial_{dx_a} \omega) \otimes \partial^J f = (\deg_0(\omega) - \deg_1(\omega))(\omega \otimes F). \quad (3.12)$$

Finally, one gets

$$(H D_2 + D_2 H)(\omega \otimes F) = (p+q + \deg_0(\omega) + \deg_0(\partial^J) - \deg_1(\omega) - \deg_1(\partial^J))(\omega \otimes F). \quad (3.13)$$

This tells that $(H D_2 + D_2 H)(\omega \otimes F) = c \cdot (\omega \otimes F)$ for $c$ a constant, which proves the claim that $H$ defines a homotopy if $c \neq 0$. The homotopy fails in the case $c = 0$. In particular, note that, by anticommutativity, $\deg_1(\omega) \leq p$ and $\deg_1(\partial^J) \leq q$. since there can only be $p$ odd forms $dz_1, \ldots, dz_p$ and $q$ odd derivation $\partial_\theta_1 \cdots \partial_\theta_q$, therefore $c = 0$ if and only if

$$\begin{align*}
\deg_0(\omega) = \deg_0(\partial^J) &= 0; \\
\deg_1(\omega) = p; \\
\deg_1(\partial^J) &= q.
\end{align*} \quad (3.14)$$

In this case the monomial $\omega \otimes F$ is of the form $dz_1 \ldots dz_p \otimes \partial_\theta_1 \cdots \partial_\theta_q f$ for $f \in \mathcal{O}_M(U)$: this element generates the Berezinian sheaf $\text{Ber}(M)$ and it is non-zero in the homology $H^*_M (\Omega^r_{M,odd} \otimes D_M(U))$, thus concluding the proof.

\begin{remark}
We observe that the previous Theorem holds true in any "geometric" category: $\mathcal{M}$ might be a real smooth or a complex analytic supermanifold, but also an algebraic supermanifold.
\end{remark}

\begin{remark}
One of the results of \cite{[12]} is that the Berezinian sheaf of a supermanifold carries a structure of right $D_M$-module. This is constructed via the action of the Lie derivative on sections of $\text{Ber}(\mathcal{M})$, which somehow parallels the analogous result on the canonical sheaf $K_M$ of an ordinary manifold $M$. Indeed, it is an easy application of Cartan calculus to see that if $\omega$ is a section of the canonical sheaf of $M$, with local trivialization given by $\omega(x)f = dx_1 \wedge \ldots \wedge dx_p f$, for $f \in \mathcal{O}_M$, then $\mathcal{L}_X(\omega) = \omega(x)f - \sum_{i} \theta_i \partial_\theta_i (X^i) \partial^J f$ for any vector field $X = \sum_{i} X^i \partial_i$. It is then not difficult to show that defining a right action $K_M \otimes T_M \rightarrow K_M$ on vector fields as $\omega \otimes X \mapsto \omega \cdot X := -\mathcal{L}_X(\omega)$ endows $K_M$ with the structure of right $D_M$-module (indeed the former action defines a flat right connection.
on $K_M$, see [11]). The same holds true in the case of the Berezinian sheaf on a supermanifold, but the construction of the action of the Lie derivative is not that straightforward, since the Berezinian is not a sheaf of forms and therefore there is no obvious generalization of the Cartan calculus on it. Nonetheless, it can be shown - for example via an analytic computation using the flow along a vector field (see also [12]) - that

$$L_X(\varphi) = (-1)^{|\varphi|(|X|)}\varphi(x) \sum_a (-1)^{|x_a|(|x_a|+|f|)} \partial_a(fX^a),$$

(3.15)

where $\varphi$ is a section of the Berezinian sheaf with local trivialization given by $\varphi = \varphi(x)f$, where $f \in \mathcal{O}_M$ and where $\varphi(x)$ is the generating section of $\text{Ber}(\mathcal{M})$. Notice that this can be re-written, more simply, as $L_X(\varphi) = (-1)^{|\varphi|(|X|)}\varphi(x) \sum_a (fX^a)\partial_a$ if one lets the derivative acting from the right, borrowing the notation from physics. The right action of vector fields making $\text{Ber}(\mathcal{M})$ into a sheaf of right $D_M$-modules is defined as [12]

$$\text{Ber}(\mathcal{M}) \otimes \mathcal{T}_M \longrightarrow \text{Ber}(\mathcal{M})$$

(3.16)

$$\varphi \otimes X \longmapsto \varphi \cdot X := (-1)^{|\varphi|(|X|)}L_X(\varphi).$$

Therefore, taking into account the action of the Lie derivative in (3.15), one gets:

$$\varphi \cdot X = -\varphi(x) \sum_a (-1)^{|x_a|(|X^a|+|f|)}\partial_a(fX^a).$$

(3.17)

It is worth noticing that the above construction, which might look somewhat artificial, comes for free in the context of the homology of the universal de Rham complex of the above theorem. The action of the Lie derivative on sections of the Berezinian emerges naturally and effortlessly as a consequence of the fact that we are working ab initio with a complex of $D_M$-modules. Indeed, the previous Theorem [3,16] has the following easy Corollary.

**Corollary 3.1 (Ber(M) is a Right D_M-Module / Lie Derivative).** Let $\mathcal{M}$ be a supermanifold. The right action

$$H^*_*(\mathcal{O}_{\mathcal{M},\text{odd}} \otimes \mathcal{O}_M \mathcal{D}_M, D) \otimes \mathcal{O}_M \mathcal{D}_M \longrightarrow H^*_*(\mathcal{O}_{\mathcal{M},\text{odd}} \otimes \mathcal{O}_M \mathcal{D}_M, D)$$

(3.18)

is uniquely characterized by $\varphi(x) \cdot \partial_a := [dz_1 \ldots dz_p \otimes \partial_{\theta_1} \otimes \ldots \partial_{\theta_p} + \partial_a] \cdot \partial_a = 0$ for any $a$, and it is given by the Lie derivative on $\text{Ber}(\mathcal{M})$.

**Proof.** One easily checks that in the homology of $D$ one has $[dz_1 \ldots dz_p \otimes \partial_{\theta_1} \otimes \ldots \partial_{\theta_p} + \partial_a] = 0$ for any $a$, which characterizes the right action of $\mathcal{D}_M$ on $H^*_*(\mathcal{O}_{\mathcal{M},\text{odd}} \otimes \mathcal{O}_M \mathcal{D}_M, D) \cong \text{Ber}(\mathcal{M})$. Explicitly, for a section $\varphi = dz_1 \ldots dz_p \otimes \partial_{\theta_1} \otimes \ldots \partial_{\theta_p}$ of the Berezian, for $f \in \mathcal{O}_M$, and a generic vector fields $X = \sum_a X^a\partial_a$, one computes using the $D_M$-module structure, that

$$\varphi \cdot X = \varphi(x) \sum_a (-1)^{|x_a|(|X^a|+|f|)}(-\partial_a(fX^a) + \partial_a fX^a)$$

$$= -\varphi(x) \sum_a (-1)^{|x_a|(|X^a|+|f|)}\partial_a(fX^a),$$

(3.19)

since the second summand is zero in the homology, thus matching the previous (3.17). \hfill \Box

Before we pass to the next section, let us stress that [11] offers a different but related point of view, closer to the one in [12], where the notion of $D_M$-module, and in particular the construction of the $D_M$-module structure on $\text{Ber}(\mathcal{M})$ is left understood, but implied by the exposition. To retrieve the $D_M$-module structure from [11] one would further need to prove that the right connection defined on $\text{Ber}(\mathcal{M})$ is flat: this actually coincide with the (3.15).

### 4. Universal Spencer Complex and its Homology

We now repeat the above construction involving the de Rham complex $\mathcal{O}_{\mathcal{M},\text{odd}}^*$ by using its dual $(\mathcal{O}_{\mathcal{M},\text{odd}}^*)^*$ instead. We start with the following definition.

**Definition 4.1 (Universal Spencer Sheaf of $\mathcal{M}$).** Given a supermanifold $\mathcal{M}$, we call the sheaf $\mathcal{D}_M \otimes \mathcal{O}_M (\mathcal{O}_{\mathcal{M},\text{odd}}^*)^*$ the universal Spencer sheaf of $\mathcal{M}$. 

Just like above, we would like to make the universal Spencer sheaf into an actual complex, by introducing a nilpotent differential on it and then compute its homology: we will see that this differential will be rather complicated with respect to the previous operator $D$ for the universal de Rham complex.

In order to get such a differential, we first need to study the Lie derivative on the polyfields $(\Omega^*_{M,odd})^*$. These can be defined recursively as follows.

**Definition 4.2 (Lie Derivative on $(\Omega^*_{M,odd})^*$).** Let $X \in T_M$ be a vector field. The Lie derivative $\mathcal{L}_X : (\Omega^*_{M,odd})^* \to (\Omega^*_{M,odd})^*$ are defined recursively via the following relations

1. $\mathcal{L}_X(f) = X(f) = \mathcal{L}_X(f)$ for any $f \in \mathcal{O}_M$ where $\mathcal{L}_X$ is the usual Lie derivative;
2. Having already defined $\mathcal{L}_X : (\Omega^k_{M,odd})^* \to (\Omega^k_{M,odd})^*$ for $h < k$, one uniquely defines $\mathcal{L}_X$ on $(\Omega^k_{M,odd})^*$ via the relation
   \[
   \mathcal{L}_X(\langle \omega, \tau \rangle) = \langle \mathcal{L}_X(\omega), \tau \rangle + (-1)^{\omega||X|}\langle \omega, \mathcal{L}_X(\tau) \rangle \quad \forall \omega \in (\Omega^*_{M,odd})^*.
   \] (4.1)

The following Lemma, which characterizes the properties of the Lie derivative on $(\Omega^*_{M,odd})^*$, holds true - for the sake of the exposition, we have deferred its proof to the Appendix.

**Lemma 4.3.** The Lie derivative $\mathcal{L}_X : (\Omega^*_{M,odd})^* \to (\Omega^*_{M,odd})^*$ has the following properties:

1. $\mathcal{L}_X(\tau) = \pi[X, \tau]$ for any $\tau \in \mathbb{P}_M$;
2. $\mathcal{L}_X$ is a superderivation of $(\Omega^*_{M,odd})^*$, i.e. the super Leibniz rule holds true:
   \[
   \mathcal{L}_X(\tau_1 \tau_2) = \mathcal{L}_X(\tau_1)\tau_2 + (-1)^{|\tau_1||\tau_2|}\tau_1 \mathcal{L}_X(\tau_2)
   \] (4.2)

   for any $\tau_1, \tau_2 \in (\Omega^*_{M,odd})^*$ and $X \in T_M$;
3. $\mathcal{L}_{fX}(\tau) = f\mathcal{L}_X(\tau) + (-1)^{|X||f|}fX\langle df, \tau \rangle$ for any $f \in \mathcal{O}_M$, $\tau \in (\Omega^*_{M,odd})^*$.

Now, using the Lie derivative on $(\Omega^*_{M,odd})^*$ we introduce the following local operator.

**Definition 4.4 (Operator $\varepsilon_x$).** Let $\tau \in (\Omega^*_{M,odd})^*$. We define the operator $\varepsilon_x$ to be such that

\[
\varepsilon_x : (\Omega^*_{M,odd})^* \xrightarrow{\tau} (\Omega^*_{M,odd})^* \xrightarrow{\varepsilon_x(\tau)} = \langle dx_a, \mathcal{L}_{\partial_a}(\tau) \rangle.
\] (4.3)

**Remark 4.5.** We observe that $\varepsilon_x$ is not invariant under the general change of coordinates. Also, it is not a derivation. On the other hand, it has the following property

\[
\varepsilon_x(f \tau) = (-1)^{|f|}\varepsilon_x(\tau) + (-1)^{|\tau|(|dx|+1)}(\partial_a f)(dx_a, \tau),
\] (4.4)

which follows from a direct computation. We now introduce the following fundamental operator.

**Definition 4.6 (The Operator $\delta$).** For $F \otimes \tau \in D_M \otimes \mathcal{O}_\omega (\Omega^*_{M,odd})^*$ such that $F$ and $\tau$ are homogeneous, we let $\delta$ be the operator

\[
\delta : D_M \otimes C (\Omega^*_{M,odd})^* \xrightarrow{\delta(F \otimes \tau)} = (\Omega^*_{M,odd})^*
\] (4.5)

\[
F \otimes \tau \xrightarrow{\delta(F \otimes \tau)} = (\partial_a \otimes \langle dx_a, \tau \rangle - (-1)^{|\tau|}F \otimes \varepsilon_x(\tau)
\]

where the index $a$ runs over all of the even and odd coordinates.

Notice that, differently from the operator $D$ on the universal de Rham complex, it is not at all obvious that the operator $\delta$ is well-defined globally on $M$, instead of being just a local operator. In the following Lemma, which is the analogous of Lemma 1.5 for $D$, we prove the properties of $\delta$. In particular, we prove that it is invariant: this happens because of a “magical” cancellation between the two transformed terms that make up $\delta$, which are clearly not invariant when taken alone.

**Lemma 4.7.** The operator $\delta$ has the following properties:

1. it is globally well-defined, i.e. it is invariant under generic change of coordinates;
2. it is $\mathcal{O}_M$-defined, i.e. it induces an operator $\delta : D_M \otimes \mathcal{O}_\omega (\Omega^*_{M})^* \to D_M \otimes \mathcal{O}_\omega (\Omega^*_{M})^*$;
3. it is nilpotent, i.e. $\delta^2 = 0$.

**Proof.** We prove separately the various points of the Lemma.
(1) We start proving the invariance of the operator under general change of coordinates. This follows from a quite lengthy computation. Adopting Einstein’s convention on repeated indices, one computes

\[ \epsilon_z(\tau) = \langle dz_b, \mathcal{O}_M^\omega(\tau) \rangle = \langle dx_a, \frac{\partial z_b}{\partial x_a} \mathcal{O}_M^\omega(\tau) \rangle = \epsilon_x(\tau) - (-1)^{|x_a|+|x_z|} \langle \frac{\partial}{\partial x_a}(\frac{\partial}{\partial z_c}) dz_c, \tau \rangle. \] (4.6)

On the other hand one has \( \frac{\partial}{\partial z_b} \otimes \langle dz_b, \tau \rangle = \frac{\partial}{\partial z_x} \otimes \langle dx_a, \tau \rangle - (-1)^{|x_a|+|x_z|} \langle \frac{\partial}{\partial x_a}(\frac{\partial}{\partial z_b}) dz_b, \tau \rangle. \) Upon using the \( \mathcal{D}_M \)-module relation one has that \( \frac{\partial}{\partial x_a} \frac{\partial}{\partial z_b} = (-1)^{|x_a|+|x_z|} \left( \frac{\partial}{\partial x_b}(\frac{\partial}{\partial z_x}) - \frac{\partial}{\partial x_a} \left( \frac{\partial}{\partial z_b} \right) \right). \) Using this, one can compute that

\[ \frac{\partial}{\partial z_b} \otimes \langle dz_b, \tau \rangle = \frac{\partial}{\partial x_a} \otimes \langle dx_a, \tau \rangle - (-1)^{|x_a|+|x_z|} \langle \frac{\partial}{\partial x_a}(\frac{\partial}{\partial z_b}) dz_b, \tau \rangle. \] (4.7)

Putting together equations (4.6) and (4.7) one finds

\[ \delta_z(\omega \otimes F \otimes \tau) = (-1)^{|\tau|} \omega \otimes F \partial_\omega \otimes \langle dx_a, \tau \rangle - (-1)^{|\tau|} (-1)^{|x_a|+|x_z|} \langle \frac{\partial}{\partial x_a}(\frac{\partial}{\partial z_b}) dz_b, \tau \rangle - (-1)^{|\tau|} \omega \otimes \epsilon_x(\tau) + (-1)^{|\tau|} (-1)^{|x_a|+|x_z|} \langle \frac{\partial}{\partial x_a}(\frac{\partial}{\partial z_b}) dz_b, \tau \rangle \]

\[ = \delta_x(\omega \otimes F \otimes \tau), \]

thus completing the proof of invariance.

(2) We now prove the \( \mathcal{O}_M \)-definition. We once again adopt Einstein convention on repeated indices. On the one hand one has

\[ \delta(F f \otimes \tau) = (-1)^{|\tau|} (F f \partial_\omega \otimes \langle dx_a, \tau \rangle - F f \otimes \epsilon_x(\tau)) \]

\[ = (-1)^{|\tau|} \left( (-1)^{|f|} F \partial_\omega \otimes f \langle dx_a, \tau \rangle - (-1)^{|f|} F \otimes \partial_\omega f \langle dx_a, \tau \rangle + F \otimes f \epsilon_x(\tau) \right). \] (4.9)

On the other hand, one computes

\[ \delta(F \otimes f \tau) = (-1)^{|f|+|\tau|} (F \otimes \langle dx_a, f \tau \rangle - F \otimes \epsilon_x(f \tau)) \]

\[ = (-1)^{|\tau|} \left( (-1)^{|f|} F \partial_\omega \otimes f \langle dx_a, \tau \rangle - (-1)^{|f|} F \otimes \partial_\omega f \langle dx_a, \tau \rangle + F \otimes f \epsilon_x(\tau) \right), \] (4.10)

where we have used the property [4.4] above. This completes the proof of the \( \mathcal{O}_M \)-definition.

(3) We prove that \( \delta^2 = 0 \). In particular, writing again \( \delta = \delta_1 + \delta_2 \), posing \( \delta_1(F \otimes \tau) := (-1)^{|\tau|} F \sum_a \partial_a \otimes \langle dx_a, \tau \rangle \) and \( \delta_2(F \otimes \tau) := (-1)^{|\tau|} F \otimes \epsilon_x(\tau) \), it is easy to see that both \( \delta_1^2 = 0 \) and \( \delta_2^2 = 0 \). A direct computation shows that the commutator \( [\delta_1, \delta_2] = \delta_1 \delta_2 + \delta_2 \delta_1 \) vanishes as well, indeed

\[ \delta_1 \delta_2(F \otimes \tau) = F \sum_a \partial_a \otimes \langle dx_a, \epsilon_x(\tau) \rangle = -\delta_2 \delta_1(F \otimes \tau), \] (4.11)

These conclude the proof. \( \square \)

The previous Lemma justifies the following definition.

**Definition 4.8 (Universal Spencer Complex of \( \mathcal{M} \)).** Let \( \mathcal{M} \) be a supermanifold. We call the pair \( (\mathcal{D}_M \otimes \mathcal{O}_M, \mathcal{O}_M^{\ast \ast})^{\ast}, \delta \) the universal Spencer complex of \( \mathcal{M} \).

We now compute the homology of the universal Spencer complex.

**Theorem 4.9 (Homology of Universal Spencer Complex).** Let \( \mathcal{M} \) be a supermanifold and let \( (\mathcal{D}_M \otimes \mathcal{O}_M, \mathcal{O}_M^{\ast \ast})^{\ast}, \delta \) be the universal Spencer complex of \( \mathcal{M} \). There exists a canonical isomorphism

\[ H_\bullet(\mathcal{D}_M \otimes \mathcal{O}_M, \mathcal{O}_M^{\ast \ast}, \delta) \cong \mathcal{O}_M. \] (4.12)
Proof. We construct a homotopy for $\delta$. In particular, we claim that the homotopy is given by

$$K(F \otimes \tau) = (-1)^{|\tau|} \sum_a \omega \otimes [F, x_a] \otimes \pi \partial_a \cdot \tau$$

(4.13)

for $F \in D_M$ and $\tau \in (\Omega_{M, odd})^*$. First we show that it is $O_M$-defined, indeed one has

$$K(F \otimes f \tau) = (-1)^{|\tau|+|f|} \sum_a [F, x_a] \otimes \pi \partial_a \cdot f \tau$$

$$= (-1)^{|\tau|+|f|} \sum_a (-1)^{|f||x_a|+|f||x_a|} [Ff, x_a] \otimes \pi \partial_a \cdot \tau$$

$$= K(F \otimes \tau)$$

(4.14)

for any $f \in O_M$. Now, we observe that in general an element of the form $Ff \in D_M$ is not homogeneous and, as such, it does not have a well-defined degree. On the other hand, one has that $Ff = \sum_j F_j$ with $F_j$ homogeneous, so without loss of generality we restrict our attention to these elements only, having a well-defined degree inside $D_M$. Relying on these considerations, we work locally, putting $\tau = f \partial^I$ for some multi-index $I$, using (4.14) we can write

$$K(F \otimes f \partial^I) = K(Ff \otimes \partial^I) = \sum_j K(F_j \otimes \partial^I)$$

(4.15)

and we consider a single term of the sum above. Again, since also $\delta$ is $O_M$-defined, one easily verifies that

$$(K\delta + \delta K)(F_j \otimes \partial^I) = \sum_a (-1)^{|x_a|+1} F_j \otimes \pi \partial_a (dx_a, \partial^I) + \sum_a [F_j, x_a] \partial_a \otimes \partial^I$$

$$= (\deg(F_j) + \deg(\partial^I)) (\omega \otimes F_j \otimes \partial^I).$$

(4.16)

The homotopy fails in the case $\deg(F_j) + \deg(\partial^I) = 0$, i.e. whenever $F$ and $\tau$ are sections of the structure sheaf $O_M$, which completes the proof. \qed

5. The Unifying Double Complex of Differential and Integral Forms

We now aim at getting the previous two sections together so that they fit in a unified framework. We start introducing the following definition, which connects the universal de Rham and Spencer complexes.

Definition 5.1 (Sheaf of Virtual Superforms). Let $M$ be a supermanifold, we call

$$\Omega_{M, odd} \otimes O_M \otimes D_M \otimes O_M (\Omega_{M, odd})^*$$

the sheaf of virtual superforms, or virtual forms for short.

Remark 5.2. Before we go on, we observe that in the triple tensor product defining the sheaf of virtual superforms, the noncommutative sheaf $D_M$ is the one which plays the pivotal role, mediating between the sheaf of differential forms and its dual.

Clearly, the differential $D$ and $\delta$ of the universal de Rham complex and of the universal Spencer complex can be lifted to the whole sheaf of virtual superforms simply by suitably tensoring them by the identity, in particular we will consider $D \otimes 1$ and $1 \otimes \delta$. These nilpotent operators commute with each other, as the following Corollary shows.

Corollary 5.1. Let $M$ be a supermanifold and let $D \otimes 1$ and $1 \otimes \delta$ act on the sheaf of virtual superforms. Then $D \otimes 1$ and $1 \otimes \delta$ commute with each other, i.e.

$$[1 \otimes \delta, D \otimes 1] := (1 \otimes \delta) \circ (D \otimes 1) - (D \otimes 1) \circ (1 \otimes \delta) = 0.$$  

(5.1)

Proof. Let $\omega \otimes F \otimes \tau$ be a virtual superform. Then one easily verifies that

$$(1 \otimes \delta) \circ (D \otimes 1)(\omega \otimes F \otimes \tau) = (-1)^{|\tau|}(d\omega \otimes F \partial_a \otimes (dx_a, \tau) - d\omega \otimes F \otimes e(\tau) +$$

$$+ (-1)^{|x_a|} dx_a \omega \otimes \partial_a F \partial_b \otimes (dx_b, \tau) - dx_a \omega \otimes \partial_b F \otimes e(\tau))$$

$$= (D \otimes 1) \circ (1 \otimes \delta)(\omega \otimes F \otimes \tau)$$

(5.2)

where we have adopted Einstein convention on repeated indices. \qed
Now, for the sake of readability and convenience, we redefine these differentials as to get the following.

**Definition 5.3 (The operators \( \hat{d} \) and \( \hat{\delta} \).)** Let \( \omega \otimes F \otimes \tau \in \Omega^{* \text{odd}}_M \otimes \mathcal{O}_M \) be a virtual superform. We define the operators

\[
\hat{d} : \Omega^{* \text{odd}}_M \otimes \mathcal{O}_M \overset{\Delta}{\rightarrow} \Omega^{* \text{odd}}_M \otimes \mathcal{O}_M \quad (5.3)
\]

\[
\hat{\delta} : \Omega^{* \text{odd}}_M \otimes \mathcal{O}_M \overset{\Delta}{\rightarrow} \Omega^{* \text{odd}}_M \otimes \mathcal{O}_M \quad (5.4)
\]

With these definitions one has the following obvious Theorem.

**Theorem 5.4.** The triple \((\Omega^{* \text{odd}}_M \otimes \mathcal{O}_M, \hat{d}, \hat{\delta})\) defines a double complex with total differential given by the sum \( \mathcal{D} := \hat{d} + \hat{\delta} \).

**Proof.** It is enough to observe that for a section \( \eta \in \Omega^{* \text{odd}}_M \otimes \mathcal{O}_M \) one has that

\[
\mathcal{D}^2(\eta) = (\hat{d}^2 + \hat{\delta}^2 + \hat{d} \hat{\delta} + \hat{\delta} \hat{d})(\eta)
\]

\[
= (-1)^{|\eta|}(0 - 0)(\eta) = 0
\]

thanks to the Corollary and to the fact that \( D \) and \( \delta \) are nilpotent. \( \square \)

The previous Theorem allows us to give the following definition

**Definition 5.5 (Virtual Superforms Double Complex).** Let \( M \) be a supermanifold. We call the double complex of sheaves \( \mathcal{V}^{**}_M := (\Omega^{* \text{odd}}_M \otimes \mathcal{O}_M, \hat{d}, \hat{\delta}) \) virtual superforms double complex. We define the bi-degrees of the double complex so that the differential \( d \) moves vertically and \( \delta \) moves horizontally.

**Remark 5.6.** This can be visualized as a second quadrant double complex, as \( \hat{\delta} \) lowers the degree in \((\Omega^{* \text{odd}}_M)\) by one.

**Remark 5.7.** Actually, we not only have a double complex but a triple complex instead, by taking the Čech cochains of the above double complex of virtual superforms. Obviously, given any sheaf \( \mathcal{F} \) and any open cover \( U = \{ U \}_{i \in I} \) of \( M \), the Čech differential \( \hat{\delta} : C^{*}(U, \mathcal{F}) \rightarrow C^{*+1}(U, \mathcal{F}) \) is independent from \( \hat{d} \) and \( \delta \), and, therefore, it commutes with both of them, justifying the following definition.

**Definition 5.8 (Čech-Virtual Superforms Triple Complex).** Let \( M \) be a supermanifold and \( U \) an open cover of \( M \). We call the triple complex \( \mathcal{V}^{***}_M := (\hat{\delta} \mathcal{V}^{**}_M, \delta, \hat{\delta}) \) Čech-virtual superforms triple complex or Čech-virtual superforms complex for short.

We now study these double and triple complexes. Clearly, to any double complex are attached two spectral sequences.

**Definition 5.9 (Spectral Sequences \( E_r^{\mathcal{D}} \) and \( E_r^{\Sigma} \)).** Let \( \mathcal{V}^{**}_M \) be the virtual superform double complex of \( M \). We call

1. \((E_r^{\mathcal{D}}, d_r^{\mathcal{D}})\) the spectral sequence of the virtual superforms double complex with respect to its vertical filtration, i.e. by first taking homology with respect to the differential \( \delta \);
2. \((E_r^{\Sigma}, d_r^{\Sigma})\) the spectral sequence of the double complex of virtual superforms with respect to its horizontal filtration, i.e. by first taking homology with respect to the differential \( d \).

Now, using ordinary spectral sequences machinery, we extract information from the double and triple complex. In particular, we start looking at \( E_r^{\mathcal{D}} \): in the next Theorem we show that differential forms arise at page one.
Theorem 5.10 (Differential Forms from $\mathcal{V}_{MC}^\bullet$). Let $\mathcal{M}$ be a supermanifold and let $(E^\Omega_{\tau}, d^\Omega_{\tau})$ be the spectral sequence of the double complex $\mathcal{V}^\bullet_{MC}$ defined as above. Then

1. $E^0_1 \cong \Omega^\bullet_{M, odd}$.
2. provided that $\mathcal{M}$ is a real or complex supermanifold, $E^0_2 = E^\Omega_{\infty} \cong \mathcal{K}_M$, where $\mathcal{K}_M$ is the constant sheaf valued in the field $\mathbb{R}$ or $\mathbb{C}$ depending of $\mathcal{M}$ being real or complex.

Proof. Everything follows easily from previous results. We prove separately the assertions.

1. By definition $E^0_1 = H_d(\mathcal{V}_{MC}^\bullet)$, so it follows from Theorem 4.9 that $E^0_1 \cong \Omega^\bullet_{M, odd}$.
2. Once again, by definition $E^0_2 = H_dH_d(\mathcal{V}_{MC}^\bullet)$, i.e. the cohomology of the de Rham complex $(\Omega^\bullet_{MC}, d)$. By the generalization of the Poincaré Lemma for supermanifolds, see for example [11], this is isomorphic to $\mathcal{K}_M$. Also, the homology is concentrated in degree zero, so that the spectral sequence converges at page two and $E^\Omega_{\infty} = E^0_2$.

These conclude the proof.

Likewise, we can find integral forms from page one of the other spectral sequence $E^\Sigma_{\tau}$, as shown in the following Theorem, mirroring the previous one for $E^\Omega_{\tau}$.

Theorem 5.11 (Integral Forms from $\mathcal{V}_{MC}^\bullet$). Let $\mathcal{M}$ be a supermanifold and let $(E^\Sigma_{\tau}, d^\Sigma_{\tau})$ be the spectral sequence of the double complex $\mathcal{V}^\bullet_{MC}$ defined as above. Then

1. $E^\Sigma_1 \cong \text{Ber}(\mathcal{M}) \otimes_{\mathcal{O}_{\mathcal{M}}} (\Omega^\bullet_{M, odd})^*$.
2. provided that $\mathcal{M}$ is a real or complex supermanifold, $E^\Sigma_2 = E^\Sigma_{\infty} \cong \mathcal{K}_M$, where $\mathcal{K}_M$ is the constant sheaf valued in the field $\mathbb{R}$ or $\mathbb{C}$ depending of $\mathcal{M}$ being real or complex.

Proof. Just like above, we prove separately the assertions.

1. By definition $E^\Sigma_1 = H_j(\mathcal{V}_{MC}^\bullet)$, so it follows from Theorem 5.6 that $E^\Sigma_1 \cong \text{Ber}(\mathcal{M}) \otimes_{\mathcal{O}_{\mathcal{M}}} (\Omega^\bullet_{M, odd})^*$.
2. Again, by definition $E^\Sigma_2 = H_jH_j(\mathcal{V}_{MC}^\bullet)$, i.e. the cohomology of the complex of integral forms $(\Sigma^\bullet_{MC}, \delta)$. There is an analogous Poincaré Lemma for integral forms on supermanifolds (see Theorem 3 in chapter 4, paragraph 8 of [11] for the statement, or Theorem 5.17 next in this section). Once again, this guarantees that, by assigning the degree as explained early on after equation (2.9), the homology is isomorphic to $\mathcal{K}_M$ and concentrated in a single degree, so that the spectral sequence converges at page two and $E^\Sigma_{\infty} = E^\Sigma_2$.

These conclude the proof.

Finally, using the Čech-Virtual superforms complex, one can prove that differential forms and integral forms compute exactly the same topological invariants related to $\mathcal{M}$, namely the (co)homology $\hat{H}^\bullet(\mathcal{M}, \mathcal{K}_M)$, which is actually the cohomology of the total complex.

For convenience, for a real supermanifold we define

$$H^\bullet_{\text{dR}}(\mathcal{M}) = H_d(\Omega^\bullet_{M, odd}(\mathcal{M})) \quad \text{and} \quad H^\bullet_{\text{sp}}(\mathcal{M}) = H_d(\Sigma^\bullet_{\text{MC}}(\mathcal{M})), \quad (5.6)$$

where $\Omega^\bullet_{M, odd}(\mathcal{M})$ are the global sections of $\Omega^\bullet_{M, odd}$. The following Theorem provides the analogous of the Čech-de Rham isomorphism in the context of real supermanifolds and proves the coincidence of the (co)homology of differential and integral forms (for a categorial construction, see Proposition 1.6.1 and the subsequent remark in [12]).

Theorem 5.12 (Equivalence of Cohomology of Differential and Integral Forms). Let $\mathcal{M}$ be a real supermanifold. The cohomology of differential forms $H^\bullet_{\text{dR}}(\mathcal{M})$ and the cohomology of integral forms $H^\bullet_{\text{sp}}(\mathcal{M})$ are isomorphic. In particular, one has

$$H^\bullet_{\text{dR}}(\mathcal{M}) \cong \hat{H}^\bullet(\mathcal{M}, \mathbb{R}_M) \cong H^\bullet_{\text{sp}}(\mathcal{M}). \quad (5.7)$$

Proof. Let us consider the Čech-de Rham complex $\mathcal{V}^\bullet_{MC}$. Taking the homology with respect to $\delta$, as done above, one reduces to the usual Čech-de Rham double complex $\mathcal{C}^\bullet(\mathcal{U}, \Omega^\bullet_{M, odd})$, where $\mathcal{U}$ is a good cover of $\mathcal{M}$. We see that the related spectral sequences converge at page two. Indeed, on the one hand $H_dH_d(\mathcal{C}^\bullet(\mathcal{U}, \Omega^\bullet_{M, odd})) \cong H^\bullet_{\text{dR}}(\mathcal{M})$, by the generalized Mayer–Vietoris sequence, having used a partition of unity of $\mathcal{M}$. On the other hand $H_dH_d(\hat{C}^\bullet(\mathcal{U}, \Omega^\bullet_{M, odd})) \cong \hat{H}^\bullet(\mathcal{M}, \mathbb{R}_M)$, by the Poincaré lemma. The same argument holds true for integral forms with the obvious modifications.
Remark 5.13 (Supermanifolds with Kähler Reduced Manifold and Hodge-to-de Rham Degeneration). In the above Theorems 5.12 we have restricted ourselves to the case of real supermanifolds. It is quite natural to ask what happens in the case of complex supermanifolds. Let us now once again work with differential forms $\Omega_{SE,odd}^{*}$ - which are now to be seen as holomorphic differential forms - , thus taking first the cohomology with respect to $\bar{\partial}$ on the triple complex $\tau_{SE}^{\bullet,\bullet,\bullet}$. Now, the cohomology of the total complex related to the double complex $C^{*}(U, \Omega_{SE,odd}^{*})$ is just $\check{H}^{*}(M, \mathcal{C}_{M})$. Indeed, by the holomorphic Poincaré Lemma, taking the cohomology with respect to $\bar{\partial}$ yields $C^{*}(U, \mathcal{C}_{M})$, so that the spectral sequence converges at page two and the total cohomology is given by $\check{H}^{*}(M, \mathcal{C}_{M})$.

On the other hand, there is no holomorphic partition of unity, so that the exactness of the generalized Mayer-Vietoris sequence fails in the complex setting. In this regard, it is a fundamental result in ordinary complex geometry that, for a compact Kähler manifold, the Hodge-to-de Rham (or Frölicher) spectral sequence converges at page one, thus giving the decomposition of the de Rham cohomology with complex coefficients $\check{H}(X, \mathcal{C}_{M})$ into vector spaces of the kind $\check{H}^{*}(X, \Omega_{X}^{p})$, i.e.

$$\check{H}^{n}(X, \mathcal{C}_{X}) \cong \bigoplus_{p+q=n} \check{H}^{q}(X, \Omega_{X}^{p}), \quad (5.8)$$

where $X$ is a generic complex manifold, see for example [15]. Remarkably, in complex supergeometry the Hodge-to-de Rham spectral sequence does not converge at page one: quite the opposite with respect to the commutative case, there are many non-zero maps at page one of the spectral sequence. We shall see this by means of an example.

Example 5.14. Let $(\mathcal{E}, \mathcal{O}_{\mathcal{E}})$ be an elliptic curve over the complex numbers. We consider a supermanifold $\mathcal{SE}$ of dimension 1|1 constructed over the elliptic curve $\mathcal{E}$, whose structure sheaf is given by the direct sum of invertible sheaves $\mathcal{O}_{SE} \doteq \mathcal{O}_{\mathcal{E}} \oplus \Pi \Theta_{\mathcal{E}}$, where $\Theta_{\mathcal{E}}$ is a theta characteristic of $\mathcal{E}$, i.e. $\Theta_{\mathcal{E}}^{\otimes 2} \cong K_{\mathcal{E}}$, for $K_{\mathcal{E}}$ the canonical sheaf of $\mathcal{E}$. We recall that since $\mathcal{E}$ is an elliptic curve we have $K_{\mathcal{E}} \cong \mathcal{O}_{\mathcal{E}}$. The supermanifold constructed this way is a genus $g = 1$ super Riemann surface, also said $N = 1$ SUSY curve (of genus 1) [10] [17]. Over an elliptic curve $\mathcal{E}$ there are four different possible choices for a theta characteristic, three of them are such that $h^{0}(\mathcal{E}, \Theta_{\mathcal{E}}) = 0$, i.e. they are even theta characteristics, and the remaining one is such that $h^{0}(\mathcal{E}, \Theta_{\mathcal{E}}) = 1$, i.e. there is a unique odd theta characteristic (and it can be identified by $\Theta_{\mathcal{E}} \cong \mathcal{O}_{\mathcal{E}}$). Here we have denoted with $h^{i}$ the dimension of the related cohomology group.

Let in particular $\mathcal{SE}$ be the genus $g = 1$ super Riemann surface with the choice of the odd theta characteristic. We are interested into study the Hodge-to-de Rham spectral sequence related to $\check{C}(U, \Omega_{SE,odd}^{*})$. Clearly, computing the cohomology with respect to the Čech differential, one gets at page one that $E_{1}^{i,q} = \check{H}^{q}(\Omega_{SE,odd}^{p})$. So one is left to study the maps $\check{H}^{i}(\Omega_{SE,odd}^{k}) \rightarrow \check{H}^{i}(\Omega_{SE,odd}^{k+1})$ for $i = 0,1$ and $k \geq 0$, induced by the de Rham differential on the $\mathbb{C}$-vector spaces $\check{H}^{i}(\Omega_{SE,odd}^{k})$. In order to do this, we note that $\mathcal{SE}$ is split and one has a decomposition of $\Omega_{SE,odd}$ as sheaf of $\mathcal{O}_{\mathcal{E}}$-modules. It is not hard to see that

$$\Omega_{SE,odd}^{k \geq 1} \cong \Theta_{\mathcal{E}}^{\otimes k} \oplus \Theta_{\mathcal{E}}^{\otimes k+2} \oplus (\Pi \Theta_{\mathcal{E}}^{\otimes k+1})^{\otimes 2} \cong \mathcal{O}_{\mathcal{E}}^{\otimes 2} \oplus \Pi \mathcal{O}_{\mathcal{E}}^{\otimes 2}, \quad (5.9)$$

where we have used that $\Theta_{\mathcal{E}} \cong \mathcal{O}_{\mathcal{E}}$ and that $\Theta_{\mathcal{E}} \cong (\Omega_{SE,odd}^{1}/(\Pi \Theta_{\mathcal{E}})\Omega_{SE,odd}^{1})_{0}$, see [11]. This decomposition allows one to easily compute the cohomology, which for both $q = 0$ and $q = 1$ reads:

$$\check{H}^{q}(\mathcal{O}_{SE}) \cong \mathbb{C}^{1|1}, \quad \check{H}^{q}(\Omega_{SE,odd}^{k \geq 1}) \cong \mathbb{C}^{2|2}. \quad (5.10)$$

Looking at the Hodge-to-de Rham spectral sequence, in turns, this leads to study the cohomology of the following sequence of maps of $\mathbb{C}$-vector spaces induced by the de Rham differential:

$$\check{H}^{0}(\mathcal{O}_{SE}) \cong \mathbb{C} \cdot \{1, \theta\}, \quad \check{H}^{0}(\Omega_{SE,odd}^{i}) \cong \mathbb{C} \cdot \{d\theta^{i}, \theta dz d\theta^{i-1}, dz d\theta^{i-1}, \theta d\theta^{i}\} \quad (5.12)$$

where $q = 0,1$. Recalling that the maps $d$ in the sequence above are odd, we separately study the two cases.

$q = 0$: this case corresponds to the map induced by the de Rham differential $d$ on the global sections, which is nothing by itself. In general, one finds that

$$\check{H}^{0}(\mathcal{O}_{SE}) \cong \mathbb{C} \cdot \{1, \theta\}, \quad \check{H}^{0}(\Omega_{SE,odd}^{i}) \cong \mathbb{C} \cdot \{d\theta^{i}, \theta dz d\theta^{i-1}, dz d\theta^{i-1}, \theta d\theta^{i}\} \quad (5.12)$$
where \( \theta \) is a global section of \( \Theta_E \cong \mathcal{O}_E \) and \( i \geq 1 \).

Now, acting with the de Rham differential on the generators one finds that the first map \( d^0 : \mathcal{H}^0(\mathcal{O}_E) \rightarrow \mathcal{H}^0(\Omega^1_{E,\text{odd}}) \) is easily identified to be such that \( \ker d^0 \cong \mathbb{C} \cdot 1 \) and \( \im d^0 \cong \mathbb{C} \cdot \delta \subset \mathcal{H}^0(\Omega^1_{E,\text{odd}}) \). The higher maps are such that \( \ker d^i \cong \mathbb{C} \cdot \{ \delta^0 d \theta \} \subset \mathcal{H}^0(\Omega^1_{E,\text{odd}}) \) and \( \im d^i \cong \mathbb{C} \cdot \{ \delta^0 d \theta^i-1 \} \subset \mathcal{H}^0(\Omega^1_{E,\text{odd}}) \). In other words the maps are non-zero on the global sections having a \( \theta \), for only in this case there is a non-vanishing derivative coming from \( d \). Using these, one finds that the only non-trivial cohomology groups contributing to \( E_2^{0,0} \) are given by

\[
E_2^{0,0} \cong \mathbb{C} \cdot 1 \cong \mathbb{C}, \quad E_2^{1,0} \cong \mathbb{C} \cdot d \theta \cong \Pi \mathbb{C}.
\]

Notice that these matches the non-vanishing cohomology groups for an ordinary elliptic curve, the difference being that those are found at page one, while in the complex supergeometric setting there is an infinite number of non-zero differentials at page one.

\( q = 1 \): this is pretty much the same as above for \( q = 0 \), upon using the Dolbeaut identification \( \mathcal{H}^0(\Omega^q_E) \cong \mathcal{H}^q(\Omega^E_1) \), so that under this isomorphism one can systematically multiply the above global sections for \( q = 0 \) by \( d \theta \in \mathcal{H}^1_{d,\theta}(\mathcal{E}) \) to obtain those for \( q = 1 \). Doing this, one finds the non-trivial cohomology groups contributing to \( E_2^{2,0} \) are given by

\[
E_2^{0,1} \cong \mathbb{C} \cdot d \theta \cong \Pi \mathbb{C}.
\]

and once again one finds an infinite number of non-zero differentials at page one.

Since the differentials at page two read \( d : E_2^{2,0} \rightarrow E_2^{2,1} \), then they are all zero by the above result in cohomology. It follows that the Hodge-to-de Rham spectral sequence for \( \mathcal{E} \) converges at page two, i.e. \( E_2 = E_{\infty} \), giving the usual Hodge decomposition of the de Rham cohomology groups.

The above example can be generalized to any super Riemann surface of genus \( g \geq 2 \): once again one finds that the Hodge-to-de Rham spectral sequence does not converge at page one, but it does converge at page two instead. Nonetheless, studying the (infinite non-trivial) differentials at page one is not as easy as in the case \( g = 1 \) above. In this case, the dimensions of the cohomology groups that appear at page one have been computed by one of the authors in [5]. In any case, the above discussion suggests the following

**Problem 5.15.** Given a complex supermanifold with Kähler associated reduced manifold, does its Hodge-to-de Rham spectral sequence always converge at page two?

Finally, notice that in the previous example the case of differential forms can be related to the case of integral forms by the supergeometric analog of *Serre duality*, which indeed involves the Berezian sheaf in the role of the dualizing sheaf, see for example [12]. From this point of view, using differential forms is again equivalent to use integral forms.

**Remark 5.16** (On Poincaré Lemmas in Supergeometry). The previous results rely heavily on the supergeometric generalization of the Poincaré Lemma, both for differential forms and integral forms. In the case of differential forms such a generalization is completely straightforward and the literature offers various proofs with different level of abstraction of the fact that \( \Omega^{p+q\vert \cdot}_{E,\text{odd}} \) is a right resolution of the constant sheaf \( \mathbb{R} \), see for example [1] [9] [11].

The story is quite different in the case of integral forms: indeed - to the best knowledge of the authors - a Poincaré Lemma for integral forms is stated in [11] (as Theorem 3 in chapter 4, paragraph 8) but no proof is provided. As it turns out that the proof of such a theorem is by not obvious, we felt like it would be good to fill this gap.

**Theorem 5.17** (Poincaré Lemma for Integral Forms). Let \( M \) be a real or complex supermanifold of dimension \( p \vert q \) and let \( (\Sigma^p_{\mathcal{M},\cdot}, \delta) \) be the complex of integral forms associated to \( M \). One has

\[
H^i(\Sigma^p_{\mathcal{M},\cdot}) \cong \begin{cases} \mathbb{K}_M & i = 0 \\ 0 & i \neq 0. \end{cases}
\]

In particular, \( H^0(\Sigma^p_{\mathcal{M},\cdot}) \) is generated by the section \( s_0 = \varphi \theta_1 \ldots \theta_q \otimes \pi \partial_{x_1} \ldots \pi \partial_{x_p} \), where \( \varphi \) is a generating section of the Berezian sheaf.
Proof. We need to construct a homotopy for the complex. In particular, working locally, we show that for any \( k \neq 0 \) there exists an homotopy \( h^k : \text{Berez}(\mathcal{M}) \otimes S^{p-1-k}_\pi \Pi T_a \rightarrow \text{Berez}(\mathcal{M}) \otimes S^{p-1-k}_\pi \) for the differential \( \delta \), that is a map such that \( h^{k+1} \circ \delta^k + \delta^{k-1} \circ h^k = \text{id}_{\text{Berez}(\mathcal{M}) \otimes S^{p-1}_\pi \Pi T_a} \).

Given a set of local coordinates for \( \mathcal{M} \), we call it \( x_a := z_1, \ldots, z_p \theta_1, \ldots, \theta_q \) and \( t \in [0, 1] \), we now consider the map \((t, x_a) \mapsto G \rightarrow t x_a \). This induces a map on sections of the structure sheaf via pull-back, \( f(x_a) \mapsto f(t x_a) \). We write \( G \) as a family of maps parametrized by \( t \in [0, 1] \), that it \( G_t : \mathcal{M} \rightarrow \mathcal{M} \), so that we can rewrite the above as a family of pull-back maps \( G_t^* : \mathcal{O}_\mathcal{M} \rightarrow \mathcal{O}_\mathcal{M} \).

Now, we define the homotopy operator as

\[
h^k(\varphi f \otimes F) := (-1)^{|f|+|F|} \varphi \sum_b (-1)^{|b|} \left( \int_0^1 dt t^Q x_b G_t^* f \right) \otimes \pi \partial_b F,
\]

where \( \varphi \) is a section of the Berezinian, \( f \) is a section of the structure sheaf and \( F \) is a polyfield of the form \( F = \pi \partial^f \) for some multi-index such that \( |l| = p - k \) and \( Q_a \) is a constant, dependent on the integral form \( s = \varphi f \otimes F \) and to be determined later on.

We now start computing \( H \delta(\varphi f \otimes F) \). We have

\[
H \delta(\varphi f \otimes F) = \varphi \sum_{a,b} (-1)^{|x_a|+|x_b|} \left( \int_0^1 dt t^{Q_a} x_b G_t^* f \right) \otimes \pi \partial_b \cdot \partial_a \partial_c F.
\]

Now let us consider \( \delta H(\varphi f \otimes F) \). We have

\[
\delta H(\varphi f \otimes F) = + \varphi \sum_a \int_0^1 dt t^{Q} G_t^* f \otimes F
\]

\[
+ \varphi \sum_a (-1)^{|x_a|} \int_0^1 dt t^{Q} x_b \partial_a G_t^* f \otimes F
\]

\[
+ \varphi \sum_a (-1)^{|x_a|+1} \int_0^1 dt t^{Q} G_t^* f \otimes \pi \partial_a \cdot \partial_x \partial_y F
\]

\[
- \varphi \sum_{a,b} (-1)^{|x_a|+|x_b|} \left( \int_0^1 dt t^{Q} x_b \partial_a (G_t^* f) \right) \otimes \pi \partial_b \cdot \partial_x \partial_y F.
\]

We see that for the last line \( Q_a = Q_a \) we need \( Q_a = Q_a + 1 \), by chain-rule. Let us now study separately the first three lines in the previous expression. Clearly, the first line \( \ref{5.15} \) yields

\[
\varphi \sum_a \int_0^1 dt t^{Q} G_t^* f \otimes F = (p + q) \varphi \left( \int_0^1 dt t^{Q} G_t^* f \right) \otimes F.
\]

Let us now look at the second line \( \ref{5.19} \): without loss of generality we can assume that \( f \) is homogeneous of degree \( \deg_{\theta}(f) \) in the theta’s, so that we can rewrite

\[
\sum_a (-1)^{|x_a|} \partial_a (G_t^* f) = \sum_{i=1}^p z_i \partial_{z_i} f(t x |t \theta) - \sum_{a=1}^q \theta_a \partial_{\theta_a} f(t x |t \theta)
\]

\[
= t^2 \frac{d}{dt} f(t x) - 2 \deg_{\theta}(f) f(t x).
\]

It follows that the equation \( \ref{5.19} \) can be computed as

\[
\varphi \sum_a (-1)^{|x_a|} \int_0^1 dt t^{Q} x_b \partial_a G_t^* f \otimes F = \varphi \int_0^1 dt t^{Q} \left( \frac{d}{dt} f(t x) - 2 \deg_{\theta}(f) f(t x) \right) \otimes F
\]

\[
= \varphi f \otimes F - \delta_{Q_a+1+\deg_{\theta}(f),0} (\varphi f(0) \otimes F) +
\]

\[
- (Q_a + 1 + 2 \deg_{\theta}(f)) \varphi \left( \int_0^1 dt t^{Q} G_t^* f \right) \otimes F,
\]

by integration by parts. Finally, denoting \( \deg_{\pi \partial}(F) \) and \( \deg_{\pi \partial}(F) \) the degree of \( F \) in the even \((\pi \partial)_0 \) and odd \((\pi \partial)_2 \) monomials of the polyfield \( F \) respectively, it can be observed that

\[
\sum_a (-1)^{|x_a|+1} \partial_a G_t^* f = (\deg_{\pi \partial}(F) - \deg_{\pi \partial}(F)) F,
\]
so that the third line (5.20) can be rewritten as
\[ \varphi \sum_a (-1)^{|x_a|+1} \int_0^1 dt^Q \cdot G^*_t f \otimes \pi \partial_a \cdot \pi \partial_a = (\deg_{\pi \partial_a} (F) - \deg_{\pi \partial_a} (F)) \varphi \left( \int_0^1 dt^Q G^*_t f \right) \otimes F. \]

Gathering together all of the contributions one has
\[ (\delta H + H \delta)(\varphi f \otimes F) = \varphi f \otimes F - \delta Q_{a+1} + \deg_{\pi \partial_a} (0) \varphi f(0) \otimes F + \]
\[ + (p + q + \deg_{\pi \partial_b} (F) - \deg_{\pi \partial_a} (F) - 2 \deg_{\pi \partial_b} (f) - Q_a - 1) \varphi \int_0^1 dt^Q G^*_t f \otimes F. \]

Let us now look at the condition on \( Q_a \) in order to have an homotopy. We have to require that
\[ Q_a = p + q + \deg_{\pi \partial_b} (F) - \deg_{\pi \partial_a} (F) - 2 \deg_{\pi \partial_b} (f) - 1. \]

This in turn leads to
\[ (\delta H + H \delta)(\varphi f \otimes F) = \varphi f \otimes F - \delta (p + q + \deg_{\pi \partial_a} (F) - \deg_{\pi \partial_a} (F) - \deg_{\pi \partial_b} (f) - \deg_{\pi \partial_b} (f) - 1) \varphi f(0) \otimes F. \] (5.29)

We now note that \( \deg_{\pi \partial_a} (F) \geq 0, 0 \leq \deg_{\pi \partial_b} (F) \leq p \) and \( 0 \leq \deg_{\pi \partial_b} (f) \leq q \), therefore the only instance in which the above fails to be a homotopy corresponds to the choices
\[ \begin{cases} 
\deg_{\pi \partial_a} (F) = 0 \\
\deg_{\pi \partial_a} (F) = p \\
\deg_{\pi \partial_b} (f) = q,
\end{cases} \] (5.30)

which in turn lead to the following generator for the only non-trivial cohomology group
\[ H^0_b (\Sigma^{P-\bullet}) = k \cdot (\varphi \theta_1 \ldots \theta_q \otimes \pi \partial_{z_1} \ldots \pi \partial_{z_p}), \] (5.31)

for \( k \in \mathbb{K} \). Note that by the very definition of \( \delta \) this element is indeed closed and not exact, since on the one hand it has the maximal amount of both theta’s and odd sections \( \pi \partial_{z_i} \)’s, thus concluding the proof. \( \square \)

Remark 5.18 (On Algebraic Versus Real or Complex Supermanifolds). With reference to the spectral sequences \( E^2 \) and \( E^2 \) related to the double complex \( \rho V^{\bullet \bullet} \), it is worth to remark that both the homotopy operators of the universal de Rham and Spencer complex are algebraic, as no integral is involved. It follows that at page one the results for \( E^2 \) and \( E^2 \) hold true also for algebraic supermanifolds and, more in general, for superschemes, so that one can indeed recover differential and integral forms from the virtual forms double complex also when working in the algebraic category. This is no longer true already at page two: indeed both the homotopy operators involved in the Poincaré Lemmas for differential and integral forms require an integration - for the case of integral forms, see above in the proof of Theorem 5.17. It follows that the related results holds true only in the smooth and analytic category, but break down in the algebraic category. Notice by the way that such a trouble also exists in the ordinary commutative setting.

Appendix A. Lie Derivative on \((\Omega^\bullet_{M,odd})^*)^\star\)

We prove the properties of the Lie derivative on \((\Omega^\bullet_{M,odd})^*)^\star\) defined in 4.2 as stated in Lemma 4.3 which we repeat here for the sake of readability.

Lemma A.1. The Lie derivative \( \Sigma_X : (\Omega^\bullet_{M,odd})^* \to (\Omega^\bullet_{M,odd})^* \) has the following properties:

1. \( \Sigma_X (\tau) = \pi[X, \pi\tau]\) for any \( \tau \in \Pi T_M \);
2. \( \Sigma_X \) is a superderivation of \((\Omega^\bullet_{M,odd})^*)^\star\), i.e. the super Leibniz rule holds true:
\[ \Sigma_X (\tau_1 \tau_2) = \Sigma_X (\tau_1) \tau_2 + (-1)^{|X||\tau_1|} \tau_1 \Sigma_X (\tau_2) \] (A.1)

for any \( \tau_1, \tau_2 \in (\Omega^\bullet_{M,odd})^* \) and \( X \in T_M \);
3. \( \Sigma fX (\tau) = f \Sigma X (\tau) + (-1)^{|X||f|/\pi X (df, \tau)} \) for any \( f \in O_M, \tau \in (\Omega^\bullet_{M,odd})^* \).
Proof. (1) We write \( \tau = \sum_a g_a \pi \partial_a \) and \( X = \sum_b f_b \partial_b \) and we pose \( \mathcal{L}_X(\tau) := \sum_c h_c \pi \partial_c \). Now, noticing that \( \langle \tau, dx_a \rangle = g_a (\tau, f_b \partial_b) = g_a \), we compute
\[
\mathcal{L}_X(g_a) = \mathcal{L}_X(\tau, dx_a) = \langle \mathcal{L}_X(\tau), dx_a \rangle + (-1)^{|\tau|} L_X(\tau, \mathcal{L}_X(dx_a))
\]
\[
= h_a + (-1)^{|X|(|\tau|+1)} \sum_b g_b (\partial_b f_a).
\]
(A.2)

It follows that \( h_a = \sum_b f_b (\partial_b g_a) - (-1)^{|X|+1} \sum_b g_b (\partial_b f_a) \), hence \( \mathcal{L}_X(\tau) = \pi [X, \tau] \).

(2) We now prove that \( \mathcal{L}_X \) is a superderivation, showing that the \( \{A.1\} \) holds true by double induction on the degrees \( \text{deg}(\tau_1), \text{deg}(\tau_2) \) in \( \text{Sym}^* \Pi T_M \). Clearly, the cases \((0,1)\) and \((1,0)\) are guaranteed by the previous point in the proof. Next, since for a 1-form \( \omega \in \Omega^1_M, \omega \)

one has
\[
\langle \tau_1 \tau_2, \omega \rangle = \tau_1 \langle \tau_2, \omega \rangle + (-1)^{|\omega||\tau_2|} \langle \tau_1, \omega \rangle \tau_2,
\]
then
\[
\mathcal{L}_X(\langle \tau_1 \tau_2, \omega \rangle) = \mathcal{L}_X(\tau_1 \langle \tau_2, \omega \rangle) + (-1)^{|\omega||\tau_2|} \mathcal{L}_X(\langle \tau_1, \omega \rangle \tau_2),
\]
(A.3)

which, by inductive hypothesis is equal to
\[
\mathcal{L}_X(\langle \tau_1 \tau_2, \omega \rangle) = \langle \mathcal{L}_X(\tau_1) \tau_2, \omega \rangle + (-1)^{|X|(|\tau_1|+|\tau_2|)} \langle \tau_1 \tau_2, \mathcal{L}_X(\omega) \rangle + (-1)^{|X|+1} \langle \tau_1 \mathcal{L}_X(\tau_2), \omega \rangle.
\]
(A.5)

On the other hand one has
\[
\mathcal{L}_X(\langle \tau_1 \tau_2, \omega \rangle) = \langle \mathcal{L}_X(\tau_1) \tau_2, \omega \rangle + (-1)^{|X|(|\tau_1|+|\tau_2|)} \langle \tau_1 \tau_2, \mathcal{L}_X(\omega) \rangle,
\]
(A.6)

so that comparing \( \{A.5\} \) with \( \{A.6\} \) one get the super Leibniz rule.

(3) Let us first prove the case \( \tau \in \Pi T_M \), using the first point of the theorem. One has
\[
\mathcal{L}_X^f(\tau) = \tau[f \mathcal{L}_X, \tau] = f \mathcal{L}_X(\tau) + (-1)^{|\mathcal{L}_X| |f|} \pi X(\mathcal{L}_X(\tau), f).
\]
(A.7)

In order to conclude the proof, one can observe that \( \mathcal{L}_X^f \) and \( \mathcal{L}_X \) are both left derivations of \( \text{Sym}^* \Pi T_M \) for \( X \) and \( f \) fixed. The same holds true for \( \pi X(\mathcal{L}_X(\tau), f) \), indeed
\[
\pi X(\mathcal{L}_X(\tau), f) = \pi X(\mathcal{L}_X(\tau), f) + (-1)^{|\tau||\mathcal{L}_X|+|f|} \tau_1 \pi X(\mathcal{L}_X(\tau), f).
\]
(A.8)

Then, thanks to the super Leibniz rule, the property proved above for \( \tau \in \Pi T_M \) only holds true for any \( \tau \in \text{Sym}^* \Pi T_M \).

\[\square\]
