Current Trends in Use of Implantable Cardioverter Defibrillators and Cardiac Resynchronization Therapy With a Pacemaker or Defibrillator in Japanese Pediatric Patients – Results From a Nationwide Questionnaire Survey –

Tsugutoshi Suzuki, MD; Naokata Sumitomo, MD, PhD; Jun Yoshimoto, MD; Aya Miyazaki, MD; Kazuhiro Hinokiyama, MD, PhD; Hiroya Ushinohama, MD, PhD; Satoshi Yasukochi, MD

Background: In Japan, the use of implantable cardioverter defibrillators (ICDs), cardiac resynchronization therapy with a biventricular pacemaker (CRTP) and CRT with a defibrillator (CRTD) in children has not been studied statistically, and dual-chamber (DDD) pacemakers are still used for pediatric CRT because of current government regulations.

Methods and Results: Data were obtained from 15 children's and 74 general hospitals through a questionnaire survey regarding the aforementioned therapies performed before 2012 in Japanese children (<16 years old). ICD, CRT with DDD, CRTP and CRTD were used in 64 (42%), 47 (31%), 34 (22%) and 7 (5%), respectively, of all cases reported (n=152). Among all CRTP and CRT-DDD cases (n=81), the use of DDD accounted for 41% in general hospitals vs. 89% in children's hospitals, and CRT-DDD and CRTP were effective in 67 cases (83%). Of 64 ICD cases, appropriate shocks were experienced in 28 cases (44%), and inappropriate shocks in 19 cases (29%). Additionally, data from the Japan Arrhythmia Device Industry Association obtained for overall device usage analysis revealed that CRTP was more commonly used in children than in adults.

Conclusions: There is an increasing need for pediatric device therapy, especially CRTP. However, many children's hospitals were still using DDD pacemakers in 2012. Although the demand for device therapy in children may be small, it is indispensable in pediatric cardiology. (Circ J 2014; 78: 1710–1716)

Key Words: Antiarrhythmic implantable device; Cardiac resynchronization therapy with a biventricular pacemaker (CRTP); Cardiac resynchronization therapy with a defibrillator (CRTD); Implantable cardioverter defibrillator (ICD); Pediatrics
Methods

The study was designed by Japanese Heart Rhythm Society Committee Members of Device Implantation in Children. A questionnaire was sent to council member hospitals of the Japanese Society of Pediatric Cardiology and Cardiac Surgery to statistically analyze the use of ICD, CRT-D, CRTP, and CRTD in pediatric (<16 years old) patients up to 2012. The questions included in the survey are listed in the Table. Data were also obtained from the Japan Arrhythmia Device Industry Association (JADIA), which is an industry organization established by Japanese manufacturers and distributors of pacemakers, ICDs and CRT devices that collects all the information on implantable devices used across Japan. The numbers of pediatric cases of ICD, CRTP and CRTD use from 2000 to 2012 and adult cases of ICD, CRTP and CRTD use in 2012

Table. Questionnaire Survey Results (n=152)

|                | ICD     | CRTP and CRT-DDD | CRTD    |
|----------------|---------|------------------|---------|
| No. of cases   | 64      | 81 (47 with DDD, 58%) | 7       |
| Date of implantation | Oct 1999 - Nov 2012 | Nov 2001 - Nov 2012 | Nov 2007 - Aug 2011 |
| Age at implantation (years) (range) | 12.6 (0.3–15.5) | 3.5 (0.2–15.5) | 13.1 (1.8–15.3) |
| Height (cm) (range) | 153 (70–179) | 90 (51–166) | 151 (65–175) |
| Weight (kg) (range) | 43.8 (5.8–110) | 10.5 (2.9–136) | 35 (5.1–55) |

ARVC, arrhythmogenic right ventricular cardiomyopathy; CAVSD, complete atrioventricular septal defect; CPVT, catecholamine-induced polymorphic ventricular tachycardia; CRTP, cardiac resynchronization therapy with a biventricular pacemaker; CRT-D, cardiac resynchronization therapy with a DDD pacemaker; CRT-D, cardiac resynchronization therapy with a defibrillator; ICD, implantable cardioverter defibrillator.
Figure 1. Pediatric use of ICD, CRTD, CRTP and CRT-DDD in Japan over the past 13 years. ICD, CRT-DDD, CRTP and CRTD were used in 64 (42%), 47 (31%), 34 (22%) and 7 (5%) cases, respectively, in the participating hospitals (A). CRT with a DDD pacemaker accounted for 96% in children’s hospitals (B) vs. 41% in the general hospitals (C) of all cases of CRTP and CRT-DDD. CRTD, cardiac resynchronization therapy with a defibrillator; CRTP, cardiac resynchronization therapy with a biventricular pacemaker; ICD, implantable cardioverter defibrillator; DDD, dual-chamber.

Figure 2. Use of cardiac resynchronization therapy with a biventricular pacemaker (CRTP) and that with a DDD pacemaker by year (A) and by age group (B). According to the questionnaire survey, DDD pacemakers were still used for CRT in nearly half of all cases of CRTP and CRT-DDD in recent years. By age, DDD pacemakers were used for CRT in all age groups, but their use was most notable in preschool children. CRTD, cardiac resynchronization therapy with a defibrillator; CRTP; cardiac resynchronization therapy with a biventricular pacemaker; ICD, implantable cardioverter defibrillator; DDD, dual-chamber.
Pediatric Use of ICD, CRTP and CRTD

The questionnaire was sent to a total of 128 institutions, and 89 institutions (70%) participated in the study. Pediatric device implantation was performed in 48 institutions (38%), but not in 41 institutions (32%). Among the responders were 15 children’s hospitals (17%) and 74 general hospitals (83%). Among general hospitals, there were equal numbers of institutions that performed device implantation in children and those that did not. Of 15 children’s hospitals, 10 (67%) were performing device implantation indicating a higher need for antiarrhythmic device therapy compared with general hospitals.

The questionnaire responses are summarized in the Table. The most frequent reasons for device therapy included hypertrophic cardiomyopathy, long QT syndrome and catecholaminergic polymorphic ventricular tachycardia for ICD patients and dilated cardiomyopathy (DCM), cardiac failure because of right ventricular pacing in congenital complete atrioventricular block, polysplenia, asplenia, tetralogy of Fallot and atrioventricular septal defect for CRTP and CRT-DDD patients. DCM was the most common condition that required CRTD. A total of 152 patients received ICD (n=64; 42%), CRT-DDD (n=47; 31%), CRTP (n=34; 22%) or CRTD (n=7; 5%) between 1999 and 2012 (Figure 1A). The use of DDD pacemakers accounted for approximately 60% (n=47) of all CRTP and CRT-DDD cases (n=81). The percentage of CRT-DDD was much higher in children’s hospital than in general hospitals [96% (25/26) vs. 40% (22/55)] (Figures 1B,C). DDD was still commonly used for CRT in recent years accounting for nearly 50% of CRTP and CRT-DDD cases (Figure 2A), and DDD was more commonly used in preschool-age children though used in all ages (Figure 2B). Of 81 cases of CRT-DDD and CRTP, cardiac conditions improved in 67 cases (83%), suggesting the effectiveness of CRT in pediatric cardiac failure. Overall, 8 cases of death were reported (Table), 5 of which occurred as a result of cardiac failure in children under 3 years of age with congenital heart disease.

Among 64 ICD patients, 19 (30%) received appropriate shocks and never experienced inappropriate shocks, but 9 (14%) experienced both appropriate and inappropriate shocks, and 10 (16%) experienced inappropriate shocks but not appropriate shocks. Twenty-six children (41%) experienced no shocks at all. Overall, about 1/3 of ICD patients experienced inappropriate shocks.

Results

Figure 3. Outcomes after implantation of implantable cardioverter defibrillator (ICD). 19 (30%) received appropriate shocks and never experienced inappropriate shocks, while 9 (14%) experienced both appropriate and inappropriate shocks, and 10 (16%) experienced inappropriate shocks but not appropriate shocks. Twenty-six children (41%) experienced no shocks at all. Overall, about 1/3 of ICD patients experienced inappropriate shocks.

Figure 4. Surgical approaches used in pediatric device implantation by age. The use of the epicardial approach was most notable in children aged 9 years or younger. From 10 to 15 years of age, the transvenous approach was more common. (Data based on questionnaire survey results.)
(16%) experienced inappropriate shocks but not appropriate shocks (Figure 3); 26 children (41%) experienced no shocks at all. Overall, approximately one-third of the pediatric population had experienced inappropriate shocks, and this rate was generally higher than that of the adult ICD patients.

The surgical approaches are summarized. The epicardial approach was used in 62% (n=94) of cases, the transvenous approach in 35% (n=53), and both approaches in 3% (n=5) (Table). The epicardial approach accounted for approximately two-thirds of the entire pediatric population and for almost all of the cases up to 9 years old (Figure 4). The epicardial approach was outnumbered by the transvenous approach after this age. For CRT, the epicardial approach was used in most cases, regardless of the child’s age and bodyweight, whereas for ICD implantation the number of transvenous approaches increased after 8 years of age or over 30 kg of bodyweight (data not shown). As for ICD coil positions, epicardial placement accounted for approximately one-third of cases, and left subcutaneous leads were used in most of them (Table).

The data from the JADIA are summarized in Figure 5. In 2012, ICD, CRTP or CRTD device implantation was performed in 9,803 cases in total, and among them there were 37 pediatric cases (<16 years of age), which accounted for 0.4% (Figure 5A). Among those 37 cases, 24 received ICD, and 12 and 1 underwent CRTP and CRTD, respectively. Figure 5B shows a comparison of the types of devices implanted in adults (2012) and children (2000–2012). ICD implantation, CRTP and CRTD accounted for 57%, 9% and 34% of adult patients and 71%, 24% and 5% of pediatric patients, respectively. It should be noted that CRTP was more frequently used in children compared with the adult population in which it was the least common therapy in 2012. The number of pediatric devices implanted increased over the past 13 years (Figure 6A); there were only 4 cases in 2000, but by the 2010s, 27 or more children were receiving an implantation every year with a maximum number of 40 in 2010. By age, pediatric device implantation was most frequently performed in children aged from 12 to 15 years (Figure 6B). A small peak was also seen from 0 to 5 years of age, indicating that implantable devices were also used in preschool children. ICDs accounted for approximately 80% of 12- to 15-year-old patients, whereas CRTP was most common in preschool patients.

Discussion

This is the first epidemiological study to investigate the number of pacemakers and defibrillators implanted in the Japanese pediatric population under 16 years of age. Based on the results obtained, an estimated 27–40 children received ICD, CRTP or CRTD annually in the 2010s, and the trend in Japanese pediatric device therapy is best characterized by increased use of CRTP in preschool children and use of DDD devices for CRT.
Pediatric Use of ICD, CRTP and CRTD

especially in children’s hospitals.

The use of DDD devices for CRT is an important issue inherent to children’s hospitals. In adults, DDD pacemakers were used for CRT before biventricular CRTP devices became available, but are no longer used. They were also conventionally used in children experiencing severe cardiac failure and dysynchrony after surgical repair of congenital heart disease. The strongest advantage of CRTP devices over CRT using a DDD pacemaker is that the former is capable of programming the interventricular delay (beneficial for interventricular dysynchrony) as well as unipolar pacing (may be used if the pacing threshold is increased after device implantation). In CRT with a DDD pacemaker, implantation of the cathode lead in the left ventricle and the anode lead in the right ventricle can worsen cardiac function because of anodal capture, which may result in single, right ventricular pacing. Based on the results of this study, however, DDD pacemakers were still used for CRT in 5–10 pediatric cases per year in the 2010s, and most of these cases were reported from children’s hospitals.

One of the main reasons that CRT-DDD is being used for children now is that the CRTP generator is too large to implant in small children and, unlike general hospitals, children’s hospitals have no choice but to use DDD pacemakers for CRT, because these facilities are not generally accredited for biventricular CRTP devices according to the Japanese government’s strict criteria for accreditation and thus CRTP devices are not covered by the national health insurance scheme. Given the promising role of CRT in congenital heart disease, coupled with the 83% improvement rate in cardiac condition after CRTP and CRT-DDD (Table), and the increasing demand for pediatric CRT especially in preschool-age children (Figures 2B, 6), it is vital that CRTP devices are available for children. Regulatory changes to allow the use of these devices in children’s hospitals, as commented by the responders to the questionnaire in the present study, are necessary.

In adult CRTP, transvenous intracardiac lead placement is commonly performed. In the present study, however, the epicardial approach was more frequently used. Although this was not an unexpected result for preschool children, it was also commonly used for older children, probably because access through the coronary sinus is often difficult in patients with congenital heart disease. As for ICD coil positions, epicardial placement accounted for approximately 80% of the latter group. The data were obtained from the Japan Arrhythmia Device Industry Association and include all the pediatric cases from 2000 to 2012 (n=280).

Figure 6. The 13-year trend in cardiac resynchronization therapy with a defibrillator (CRTD), CRT with a biventricular pacemaker (CRTP) and implantable cardioverter defibrillator (ICD) implantation in Japanese pediatric patients under 16 years of age. (A) ICDs were the only device used until 2003. Thereafter, the total number of devices implanted increased gradually up to 24 cases of ICD, 14 cases of CRTP and 2 cases of CRTD in 2010s. (B) Number of pediatric cases of CRTD, CRTP and ICD implanted by age. There were 2 peaks, a small peak at 0–5 years of age and a larger peak at 12–15 years of age. The former peak indicates that antiarrhythmic device implantation, primarily CRTP, was also performed in preschool-age children, while ICDs accounted for approximately 80% of the latter group. The data were obtained from the Japan Arrhythmia Device Industry Association and include all the pediatric cases from 2000 to 2012 (n=280).
Sudden cardiac death may occur a long time after congenital heart disease surgery, and the efficacy of ICD in preventing such deaths has been reported. Cuo et al reported that echocardiogram is very effective in determining whether CRT is indicated and in selecting the position of CRT in patients with a single ventricle. The need for pediatric ICD implantation, CRTP and CRTD is still small in Japan, but efficacy of these devices has already been reported in other countries, regardless of the patient’s ethnic background.

To meet the potential increase in the demand for device therapy in Japan, these devices must be made available to children’s hospitals as well.

Conclusions

Based on the results of the present study, the overall demand for ICD, CRTP and CRTD is estimated to be from 27 to 40 cases per year in the 2010s in the Japanese pediatric population. The current government accreditation criteria for CRTP device are imposing a challenge to children’s hospitals. Although the need is small, the device is essential for the pediatric population. Prompt action is recommended to solve this problem.
