Asymptotic distribution of estimators in reduced rank regression settings when the regressors are integrated

May 5, 2014

Abstract

In this paper the asymptotic distribution of estimators is derived in a general regression setting where rank restrictions on a submatrix of the coefficient matrix are imposed and the regressors can include stationary or I(1) processes. Such a setting occurs e.g. in factor models. Rates of convergence are derived and the asymptotic distribution is given for least squares estimators as well as fully-modified estimators. The gains in imposing the rank restrictions are investigated. A number of special cases are discussed including the Johansen results in the case of cointegrated VAR(p) processes.

Keywords: rank restricted regression, asymptotic distribution, integration

1 Introduction

In this paper a multivariable time series \((y_t)_{t \in \mathbb{Z}}, y_t \in \mathbb{R}^s\), is modeled as a linear function of two processes \((z_t^r)_{t \in \mathbb{Z}}, z_t^r \in \mathbb{R}^{m_r}\) and \((z_t^u)_{t \in \mathbb{Z}}, z_t^u \in \mathbb{R}^{m_u}\) (where 'r' stands for restricted and 'u' for unrestricted) using the following model:

\[
y_t = b_r z_t^r + b_u z_t^u + u_t, t = 1, \ldots, T
\]

where \(b_r = O \Gamma'\) is of rank \(n < \min(s, m_r)\). Such a situation can occur e.g. for panel data sets where both \(s\) and \(m_r\) are large. Throughout all variables will be assumed to be either stationary or (co-)integrated. Details on the assumptions for the processes are given below. For the moment assume that \((u_t)_{t \in \mathbb{Z}}\) is an independent identically distributed (iid) process.

In this situation the asymptotics for the OLS estimators (Park and Phillips, 1988; Park and Phillips, 1989) and fully modified (Phillips, 1995) estimators neglecting the rank restriction are well documented in the literature. However, neglecting the rank restriction in the case

*Correspondence to: tel.: ++43 50 550 6669, e-mail: Dietmar.Bauer@ait.ac.at.
that \( m_r \) and \( s \) are large, the number of parameters to be estimated equals \((m_r + m_u)s\) which might require excessively large samples in order to allow for reasonable accuracy. As an alternative then rank restricted regression (RRR) can be used in order to reduce the number of parameters greatly.

The RRR framework of equation (1) is also of importance for the estimation involved in subspace methods, (see e.g. Larimore, 1983; Bauer and Wagner, 2002). In these methods a RRR of the type (1) is the central step in the estimation. Thus the understanding of the asymptotic properties of the corresponding estimators needs a thorough understanding of the asymptotic properties of estimators for (1).

If all involved processes are stationary the asymptotic theory of RRR estimators based on OLS is presented in (Reinsel and Velu, 1998). There consistence and asymptotic normality of the estimated coefficient matrices is stated for the (generic) special case that all singular values of \( b_r \) are distinct. Further expressions for the asymptotic variance matrix are provided using implicitly defined quantities which, hence, are not easy to interpret or implement.

For a cointegrated process \( X_t \) letting

\[
y_t = \Delta X_t = X_t - X_{t-1}, \quad z_r^r = X_{t-1}, \quad z_u^r = [\Delta X_{t-1}', \ldots, \Delta X_{t-p}']'
\]
equation (1) corresponds to the Johansen framework (Johansen, 1995). Also in this case the asymptotics of quasi maximum likelihood estimators are well known. Although the original material focuses on the estimation of the cointegrating relations \( \Gamma \) extracted as the right factor in the product \( b_r = O \Gamma' \), the asymptotics for the full estimator \( \hat{b}_r \) can be derived based on these results, see the evaluations in (Johansen, 1995). The arguments given there rely on stationarity of \( y_t \) and \( \Gamma'X_{t-1} \) as well as on the fact that the rank restriction only restricts the coefficients corresponding to the nonstationary components of \( X_{t-1} \) as will be demonstrated below.

Equation (1) extends this framework by allowing for more general processes \( z_r^r \) and \( z_u^r \). It will be shown below (see Theorem 3.1) that there exist nonsingular transformations \( T_y, T_r \) such that

\[
\tilde{b}_r := T_y b_r T_r^{-1} = \begin{bmatrix}
I_{c_y} & 0_{c_y \times (c_r - c_y)} & 0_{c_y \times (m_r - c_r)} \\
0_{(s-c_y) \times c_y} & 0_{(s-c_y) \times (c_r - c_y)} & 0_{(s-c_y) \times (m_r - c_r)}
\end{bmatrix}
\begin{bmatrix}
I_{c_y} & 0 & 0 \\
0 & \hat{O}_2 & 0
\end{bmatrix}
\begin{bmatrix}
I_{c_y} & 0 & 0 & 0 \\
0 & \hat{O} & 0 & \hat{\Gamma}_{32}^r
\end{bmatrix}
\]

and in \( \tilde{z}_r^r = T_r z_r^r \) the first \( c_r \) coordinates are integrated, the remaining ones being stationary.

In the Johansen framework \( c_y = 0 \) holds while in this paper \( 0 \leq c_y \leq n \leq s \) is allowed
for. Also in \( \mathcal{T}_y(y_t - b_u \bar{z}_t^u) \) the first \( c_y \) components are integrated the remaining ones being stationary.

In this extended situation the asymptotics of (Johansen, 1995) do not apply as can be seen from the following arguments: Using the notation \( \langle a_t, b_t \rangle = T^{-1} \sum_{t=1}^T a_t b_t' \) for processes \( (a_t)_{t \in \mathbb{Z}}, (b_t)_{t \in \mathbb{Z}} \) the consistency proof in Lemma 13.1. of (Johansen, 1995) relies on solving the generalized eigenvalue problem

\[
\lambda \langle \bar{z}_t^{r,\pi}, z_t^{r,\pi} \rangle v - \langle \bar{z}_t^{r,\pi}, y_t^{\pi} \rangle \langle y_t^{\pi}, y_t^{\pi} \rangle^{-1} \langle y_t^{\pi}, z_t^{r,\pi} \rangle v = 0.
\]

Here \( a_t^{\pi} \) denotes the residuals of a regression onto \( z_t^u \). Consistency is shown by transforming the problem using the matrix \( A_T = [\hat{\Gamma} \perp T^{-1/2}, \hat{\Gamma}] \) (changing the order of the block column to correspond to our ordering as used below) where the columns of the matrix \( \hat{\Gamma} \perp, (\hat{\Gamma} \perp)' \hat{\Gamma} \perp = I \) span the orthogonal complement of the space spanned by the columns of \( \hat{\Gamma} \). Correspondingly for \( c_y = 0 \) in \( A_T' z_t^{r,\pi} \) the first components are nonstationary but scaled by \( T^{-1/2} \) and the remaining ones stationary. In the transformed problem

\[
\lambda A_T' \langle z_t^{r,\pi}, z_t^{r,\pi} \rangle A_T w - A_T' \langle z_t^{r,\pi}, y_t^{\pi} \rangle \langle y_t^{\pi}, y_t^{\pi} \rangle^{-1} \langle y_t^{\pi}, z_t^{r,\pi} \rangle A_T w = 0
\]

all matrices converge to block diagonal matrices. Thus the corresponding eigenvalues and matrix of eigenvectors \( V_T \) (with a suitable choice of the basis) converge. The eigenvectors of the transformed problem corresponding to the nonzero eigenvalues are related via \( V_T = A_T^{-1} W_T = [\hat{\Gamma} \perp, (\hat{\Gamma} \perp)' \hat{\Gamma} \perp] W_T \) (assuming without restriction of generality \( \hat{\Gamma} \hat{\Gamma} \perp = I_n \)) implying that \( T^{1/2} \hat{\Gamma} \perp W_T \) converges to zero in probability. No almost sure (a.s.) results and no sharper bounds on the order of convergence are provided in (Johansen, 1995).

For \( c_y > 0 \), however, \( \hat{\Gamma}' \bar{z}_t^r \) is nonstationary and \( A_T' \langle \bar{z}_t^{r,\pi}, \bar{z}_t^{r,\pi} \rangle A_T \) does not converge. Using instead \( \hat{A}_T \) as

\[
\hat{A}_T' = \begin{bmatrix}
T^{-1/2} I_{c_y} & 0 & 0 \\
0 & T^{-1/2} I_{c_y - c_y} & 0 \\
0 & 0 & \hat{\Gamma}_3^{r,\perp} \\
0 & 0 & \hat{\Gamma}_3^{r,\perp}
\end{bmatrix}
\]

where \( \hat{\Gamma}_3^{r,\perp} \) is a block diagonal matrix leads to convergence for the generalized eigenvalue problem. Thus again \( V_T = \hat{A}_T^{-1} W_T \) converges, where the first \( c_y \) columns corresponding to the eigenvalue \( \lambda = 1 \) converge to \( [I_{c_y}, 0]' \). Consequently also \( W_T = \hat{A}_T V_T \) converges. However, the heading \( c_y \times c_y \) subblock of this matrix equals \( T^{-1/2} I_{c_y} \) and hence converges to zero as does the whole block column. Multiplying the corresponding block column with \( T^{1/2} \) the
heading subblock equals the identity matrix as required, but the orders of convergence for
the remaining blocks are reduced by this order and hence the remaining arguments in the
proof of Lemma 13.1 of (Johansen, 1995) do no longer apply. Therefore this approach cannot
be used in order to show consistency for the estimator of $\hat{\Gamma}^*$ and thus also not of $\hat{O}$. Due
to this complication (Bauer and Wagner, 2002) were led to provide an adapted estimator by
setting the remaining block rows of the first block column of $V_T$ equal to zero. In this paper
a different route in the proof for consistency of the estimator for $b_r$ is provided showing that
the adaptation is not needed.

In addition to the changes in the consistency proofs also the derivation of the asymptotic
distribution of the estimators $\hat{\Theta}$ and $\hat{\Gamma}$ of $\tilde{\Theta}$ and $\tilde{\Gamma}$ as provided in Lemma 13.2. of (Johansen,
1995) for the case $c_y = 0$ cannot be used in the case $c_y > 0$ as can be seen from these
arguments: In the last equation on p. 182 the last term $(\tilde{O} - \tilde{O})\hat{\Gamma}^\prime(\tilde{z}_{t,N}^\pi, \tilde{z}_{t,N}^{r,\pi})$ is shown to tend
to zero using consistency for $\tilde{O}$ and stationarity of $\hat{\Gamma}^\prime z_{t}^{r,\pi}$ for $c_y = 0$. For $c_y > 0$, however,$\hat{\Gamma}^\prime z_{t}^{r,\pi}$ contains nonstationary components such that $\langle \hat{\Gamma}^\prime z_{t}^{r,\pi}, \tilde{z}_{t}^{r,\pi} \rangle = OP(T)$ and moreover
converges in distribution to a nondegenerate distribution when divided by $T$. Hence even
if $(\tilde{O} - \tilde{O})$ is estimated superconsistently such that $T(\tilde{O} - \tilde{O})$ converges in distribution, the
term $(\tilde{O} - \tilde{O})\hat{\Gamma}^\prime(\tilde{z}_{t,N}^\pi, \tilde{z}_{t,N}^{r,\pi})$ in the last equation on p. 182 does not vanish. Thus also for the
asymptotic distribution the proof in (Johansen, 1995) does not apply for the case $c_y > 0$ and
a more detailed analysis is needed. It is the main goal of the paper to close this gap in the
literature.

In this paper two different estimators are considered: RRR estimator based on the un-
restricted OLS estimator as well as based on the fully modified unrestricted estimator of
(Phillips, 1995). The main contributions of the paper are:

- A full discussion of the asymptotic properties of the RRR estimators including condi-
tions for consistency, derivation of the asymptotic distribution of the estimators under
the condition of known rank $n$ is provided.

- For the RRR estimator based on OLS almost sure (a.s.) rates of convergence are
provided, improving the results in the literature which provide only in probability con-
vergence.

- Furthermore in all cases the asymptotic distribution will be given explicitly and a de-
tailed comparison of the relative advantages in a number of special cases is provided.
The organization of this paper is the following: The next section presents the various estimation algorithms while their corresponding asymptotic properties are discussed in section 3. Section 4 illustrates the results using a number of special cases. Finally section 5 summarizes the paper. All results are proved in Appendix A. A summary of the notation is contained in Appendix B.

2 Estimation Algorithms

In this paper four different estimators for the coefficient matrices \( b_r, b_u \) in equation (1) based on observations for time instants \( t = 1, \ldots, T \) are considered. Throughout as above the notation \( \langle a_t, b_t \rangle := T^{-1} \sum_{t=1}^{T} a_t b'_t \) will be used (somewhat sloppily using \( a_t, b_t \) for the processes \( (a_t)_{t \in \mathbb{Z}} \) and \( (b_t)_{t \in \mathbb{Z}} \) and for the variables \( a_t, b_t \) for given time instant \( t \) respectively).

Using this notation the ordinary least squares (OLS) estimator (that ignores the knowledge on the rank constraint \( \text{rank}(b_r) = n \)) can be written as

\[
\hat{\beta}_{\text{OLS}} = (y_t, z_t)(z_t, z_t)^{-1}, \quad \hat{\beta}_{\text{OLS}} = [\hat{\beta}_{\text{OLS},r}, \hat{\beta}_{\text{OLS},u}].
\]

If

\[
\Xi_+ = (y_t, y_t)^{-1}, \quad y_t = y_t - \langle y_t, z_t \rangle (z_t, z_t)^{-1} z_t,
\]

the rank restricted estimator maximizing the quasi maximum likelihood based on the assumption of iid Gaussian residuals can be defined as

\[
\hat{\beta}_{\text{RRR}} = \arg \min_{\beta = [\beta_r, \beta_u] \in \mathbb{R}^{m_r + m_u}, \text{rank}(\beta_r) = n} \text{tr} \left( \Xi_+ \sum_{t=1}^{T} (y_t - \beta_r z_t^r - \beta_u z_t^u)(y_t - \beta_r z_t^r - \beta_u z_t^u)' \Xi_+ \right)
\]

and is given by

\[
\hat{O} = (\Xi_+)^{-1} \hat{U}_n \hat{S}_n, \hat{G}' = \hat{V}'_n (\Xi'_p)^{-1}, \hat{\beta}_{\text{RRR},r} = \hat{O} \hat{G}', \hat{\beta}_{\text{RRR},u} = \langle y_t - \hat{\beta}_{\text{RRR},r} z_t^r, z_t^u \rangle (z_t^u, z_t^u)^{-1} (2)
\]

using the SVD

\[
\Xi_+ \hat{\beta}_{\text{OLS},r} \Xi'_p = \hat{U}_n \hat{S}_n \hat{V}'_n + \hat{R}_n
\]

where \( \hat{U}_n \) denotes the matrix having as columns the singular vectors corresponding to the dominant singular values \( \hat{\sigma}_1 \geq \hat{\sigma}_2 \geq \ldots \geq \hat{\sigma}_n > 0 \) contained as the diagonal in the diagonal matrix \( \hat{S}_n \). The corresponding right singular vectors are contained in \( \hat{V}_n \). Finally \( \hat{R}_n \) constitutes the approximation error. Here \( \Xi'_p = (z_t^r, z_t^u)^{1/2} \) (where \( X^{1/2} \) denotes the
symmetric matrix square root of the square matrix $X$ and $z_t^\pi$ denote residuals from regression of $z_t^\pi$ onto $z_t^\nu$). Clearly the estimator $\hat{\beta}_{RRR,r}$ does not depend on the decomposition of $\hat{O}\hat{G}'$ into $\hat{O}$ and $\hat{G}'$.

Note that for this choice of $\tilde{\Xi}_+$ and $\tilde{\Xi}_-$ the columns of $\hat{G}'$ can also be interpreted as the eigenvectors to the generalized eigenvalue problem
\[
\langle z_t^\pi, z_t^\pi \rangle \hat{G} \hat{S}^{-2}_{n} = \langle z_t^\pi, y_t^\pi \rangle \langle y_t^\pi, y_t^\pi \rangle^{-1} \langle y_t^\pi, z_t^\pi \rangle \hat{G}.
\]

As can be verified straightforwardly the corresponding estimate $\hat{O}$ equals the coefficients for regressing $y_t^\pi$ onto $\hat{G}'z_t^\pi$. Thus in the Johansen framework the Johansen estimators are obtained.

(Phillips, 1995) discusses the fully-modified (FM) estimators as an alternative to least squares estimation. The fully modified OLS estimator (FM-OLS) of $\beta$ is defined as
\[
\hat{\beta}^{+}_{OLS} := \left( y_t, z_t \right) - \hat{\Delta}_a, \Delta_z - \hat{\Omega}_{a, \Delta z} \hat{\Omega}_{\Delta z, \Delta z}^{-1} \left( \langle \Delta z_t, z_t \rangle - \hat{\Delta} \Delta_z, \Delta_z \right) \left( z_t, z_t \right)^{-1} \tag{3}
\]
where for processes $(a_t)_{t \in \mathbb{Z}}$ and $(b_t)_{t \in \mathbb{Z}}$ the estimates
\[
\hat{\Omega}_{a,b} := \sum_{j=1}^{T-1} w(j/K) \hat{\Gamma}_{a,b}(j), \quad \hat{\Delta}_{a,b} := \sum_{j=0}^{T-1} w(j/K) \hat{\Gamma}_{a,b}(j)
\]
are used. As usual $\Delta z_t := z_t - z_{t-1}$. Here $\hat{\Gamma}_{a,b}(j) := \langle a_t, b_{t-j} \rangle = T^{-1} \sum_{t=1}^{T} a_t b_{t-j}$ denotes the estimated covariance sequence where observations outside of the observed sample are treated as zeros. Further $\hat{\Omega}_{a, \Delta z}$ is estimated using the residuals $\hat{u}_t = y_t - \hat{\beta}_{OLS} z_t$. Throughout we will use the subscripts to indicate the processes involved. Additionally superscripts indicate components of the processes. A slight difference to the notation of e.g. Phillips (1995) is that for the integrated processes $z_t$, say, we index by $\Delta z$ rather than only $z$.

Consequently for stationary processes $(a_t)_{t \in \mathbb{Z}}$ and $(b_t)_{t \in \mathbb{Z}}$ it follows that $\hat{\Omega}_{a,b}$ and $\hat{\Delta}_{a,b}$ are estimators of the long-run-covariance and the one-sided long run covariance matrices defined as
\[
\Omega_{a,b} = \sum_{j=-\infty}^{\infty} \mathbb{E} a_j b'_0, \quad \Delta_{a,b} = \sum_{j=0}^{\infty} \mathbb{E} a_j b'_0.
\]

For the kernel function $w(\cdot)$ occurring in this definition we will use the standard assumptions (cf. Phillips, 1995):

**Assumption K:** The kernel function $w(.) : \mathbb{R} \to [-1, 1]$ is a twice continuously differentiable even function with
(a) \( w(0) = 1, w'(0) = 0, w''(0) \neq 0 \)

(b) \( w(x) = 0, |x| \geq 1 \) with \( \lim_{|x| \to 1} w(x)/(1 - |x|)^2 = \text{constant} \)

Further the bandwidth parameter \( K \) in the kernel estimates is chosen proportional to \( c_T T^b \) for some \( b \in (1/4, 2/3) \) where \( c_T \) is slowly varying at infinity (i.e. \( c_T x / c_T \to 1, \forall x > 0 \)).

Analogously to the RRR estimator derived from the OLS estimator we derive the new fully modified RRR estimator (henceforth denoted as FM-RRR) from the FM-estimator using the SVD

\[
\tilde{\Xi} + \hat{\beta}^+_{OLS, x} (z_t, z_t)^{1/2} = \hat{U}_n^+ \hat{S}_n^+ (\hat{V}_n^+)^{'},
\]

where as before \( \hat{U}_n^+ \) denotes the matrix of left singular vectors, \( \hat{S}_n^+ = \text{diag}(\hat{s}_1^+, \hat{s}_2^+, \ldots, \hat{s}_n^+) \) is the diagonal matrix containing the dominant estimated singular values \( \hat{s}_1^+ \geq \hat{s}_2^+ \geq \ldots \geq \hat{s}_n^+ > 0 \) decreasing in size and the columns of \( \hat{V}_n^+ \) contain the corresponding right singular vectors.

The estimator under the rank restriction \( \text{rank}(\beta) = n \) then is defined as

\[
\hat{\beta}^+_{RRR, x} = (\tilde{\Xi} + \hat{\beta}^+_{OLS, x} (z_t, z_t)^{-1/2}, \hat{\beta}^+_{RRR, u} = \hat{\beta}^+_{OLS, u} - (\hat{\beta}^+_{OLS, x} - \hat{\beta}^+_{RRR, x})(z_t^u, z_t^u)^{-1}.
\]

(5)

3 Results

In this paper the following assumptions on the data generating process (dgp) will be used:

**Assumption P:** The process \((y_t)_{t \in \mathbb{Z}}\) is generated according to (1) with \( u_t = \Lambda \varepsilon_t \) (\( \Lambda \in \mathbb{R}^{s \times k} \) of full row rank) where \((z_t^r)_{t \in \mathbb{Z}}\) and \((z_t^u)_{t \in \mathbb{Z}}\) are processes such that for some orthogonal matrices

\[
H_r = [H_{r,1}, H_{r,1}], H_u = [H_{u,1}, H_{u,1}], (H_{r,1}) \in \mathbb{R}^{m_r \times c_r}, H_{u,1} \in \mathbb{R}^{m_u \times c_u}
\]

we have

\[
\text{diag}(\Delta(L) I_{c_r}, I_{m_r - c_r}) H_r z_t^r = v_t, \quad t \in \mathbb{Z}, \quad \text{diag}(\Delta(L) I_{c_u}, I_{m_u - c_u}) H_u z_t^u = w_t, \quad t \in \mathbb{Z},
\]

where \( \Delta(L) = 1 - L \) denotes the difference operator (\( L \) denoting the backward shift operator) and the joint vector \( \nu_t := [v_t^{'}, w_t^{'}]^{'} \) is a stationary process generated according to

\[
\nu_t = \sum_{j=1}^{\infty} C_j \varepsilon_{t-j}
\]

where \( \sum_{j=1}^{\infty} j^a ||C_j|| < \infty \) for some \( a > 3/2 \) and where for the transfer function \( c(z) := [c_v(z)', c_w(z)'] = \sum_{j=1}^{\infty} C_j z^j \) (with \( z \) denoting a complex variable) the matrix \( c(1) \) is of full
row rank. Additionally it is assumed that

\[ \mathbb{E} \left[ \begin{bmatrix} H'_{r, \perp} z^r_t \\ H'_{u, \perp} z^u_t \end{bmatrix} \right] \left[ \begin{bmatrix} H'_{r, \perp} z^r_t \\ H'_{u, \perp} z^u_t \end{bmatrix} \right]' > 0. \]

Here \((\varepsilon_t)_{t \in \mathbb{Z}}\) is an iid process with zero mean, nonsingular variance \(\Sigma\) and finite fourth moments. Finally \(H'_{r,\perp} z^r_0 = 0\) and \(H'_{u,\perp} z^u_0 = 0\). □

Note that summation for \(\nu_t\) starts at \(j = 1\). Thus uncorrelatedness of the regressors with the noise is built into the assumptions. The assumptions imply that \(z^r_t\) and \(z^u_t\) are I(1) processes such that the cointegrating rank of the joint process equals the sum of the cointegrating ranks of the two processes.

The assumption of zero initial conditions is not important and can be replaced with the assumption of deterministic initial conditions, i.e. assuming that modeling is performed conditional on initial conditions.

The noise is assumed to constitute an iid sequence which is somewhat restrictive. Weaker assumptions are possible but make the asymptotic distributions more involved. Further note that the same noise \(\varepsilon_t\) is used to generate the regressors as well as the residuals in the estimation equation. Consequently lagged \(y_t\)'s are admitted as regressors and some dynamics may be included in the model, alleviating the iid assumption.

Furthermore these assumptions exclude deterministic terms such as the constant as regressors which are discussed separately below.

The assumptions on the data generating process lead to the following representation result:

**Theorem 3.1** Let Assumption P hold where \(n = \text{rank}(b_r), b = [b_r, b_u]\).

(I) Let \(c_y \leq n\) denote the rank of \(b_r H_{r,\perp}\). Then the cointegrating rank of \((z^r_t)_{t \in \mathbb{Z}}\) is \(m_r - c_r\) and the cointegrating rank of \((y_t - b_u z^u_t)_{t \in \mathbb{Z}}\) is \(s - c_y\).

(II) There exist nonsingular matrices \(T_y \in \mathbb{R}^{s \times s}, T_{z,r} \in \mathbb{R}^{m_r \times m_r}\) and \(T_{z,u} \in \mathbb{R}^{m_u \times m_u}\) such that

\[ \tilde{y}_t = \begin{bmatrix} \tilde{y}_{t,1} \\ \tilde{y}_{t,2} \end{bmatrix} = T_y (y_t - b_u z^u_t) = b_r \tilde{z}_t + \tilde{\varepsilon}_t = \begin{bmatrix} I_{c_y} & 0 & 0 \\ 0 & 0 & \tilde{b}_{2,3} \end{bmatrix} \begin{bmatrix} \tilde{z}_{t,1} \\ \tilde{z}_{t,2} \\ \tilde{z}_{t,3} \end{bmatrix} + \begin{bmatrix} \tilde{\varepsilon}_{t,1} \\ \tilde{\varepsilon}_{t,2} \end{bmatrix}, \]

\[ \tilde{z}_t = T_{z,r} z^r_t = \begin{bmatrix} \tilde{z}_{t,1} \\ \tilde{z}_{t,2} \\ \tilde{z}_{t,3} \end{bmatrix}, \quad \tilde{z}^u_t = T_{z,u} z^u_t = \begin{bmatrix} \tilde{z}^u_{t,1} \\ \tilde{z}^u_{t,2} \\ \tilde{z}^u_{t,3} \end{bmatrix} \]

where \(\Delta(L) \tilde{z}_{t,1} = \tilde{c}_{z,1}(L) \varepsilon_t, \Delta(L) \tilde{z}_{t,2} = \tilde{c}_{z,2}(L) \varepsilon_t, \Delta(L) \tilde{z}^u_{t,1} = \tilde{c}_{z,u}(L) \varepsilon_t, t \in \mathbb{Z}\) (\(L\) denoting the backward shift operator) and the matrix \([\tilde{c}_{z,1}(1)', \tilde{c}_{z,2}(1)', \tilde{c}_{z,u}(1)']\) is of full column rank, and \((\tilde{z}_{t,3})_{t \in \mathbb{Z}}\) and \((\tilde{z}^u_{t,2})_{t \in \mathbb{Z}}\) are stationary processes with nonsingular spectrum at \(z = 1\).
The result is proved in Appendix A. It builds the main representation of the regression on which the asymptotic results are based upon. Note that the matrices $\mathcal{T}_y, \mathcal{T}_{z,u}$ and $\mathcal{T}_{z,r}$ separating the non-stationary and stationary directions of the various processes are not unique and the theorem only ascertains the existence. The restrictions on the ranks of the various matrices ensures that the various components are either stationary processes which are not over differenced or integrated processes which are not cointegrated.

Under these assumptions it is well known that the OLS estimators are weakly consistent (Park and Phillips, 1988; Park and Phillips, 1989). Furthermore almost sure consistency as well as the convergence rate $\hat{\beta}_{OLS} - b = O(\sqrt{\log \log T/T})$ (i.e. $\sqrt{T/\log \log T}(\hat{\beta}_{OLS} - b)$ is almost surely (a.s.) bounded) can be derived, see e.g. (Bauer, 2009). Additionally their asymptotic distribution is also well documented: Let $\mathcal{T}_z = \text{diag}(\mathcal{T}_{z,r}, \mathcal{T}_{z,u})$ and let $D_z = \text{diag}(D_{z,r}, D_{z,u})$, $D_{z,r} = \text{diag}(T^{-1}I_c, T^{-1/2}I_{m_r-c_r})$, $D_{z,u} = \text{diag}(T^{-1}I_u, T^{-1/2}I_{m_u-c_u})$. Then one obtains

$$
\mathcal{T}_y(\hat{\beta}_{OLS} - b)\mathcal{T}_z^{-1}D_z^{-1} \xrightarrow{d} \begin{bmatrix} M_r & Z_r & M_u - M_rN_r & Z_u - Z_rE\tilde{z}_{t,3}(\tilde{z}_{t,2})'(E\tilde{z}_{t,2}(\tilde{z}_{t,2})')^{-1} \end{bmatrix}
$$

where (using the notation\footnote{Here and below $\int dE W'$ is the usual shorthand notation for $\int_0^1 d(E(u)W(w))'$ for Brownian motions $E(w), W(w), w \in [0, 1]$. Analogously $\int WW'$ is short for $\int_0^1 W(w)W(w)'dw$.}) $f(E, W) = \int dEW'(\int WW')^{-1}$

$$
M_r = f(\mathcal{T}_yAW, W^\Pi_z), \quad M_u = f(\mathcal{T}_yAW, W_u), \quad N_r = \int W_zW_u' \left(\int W_uW_u'\right)^{-1},
$$

$$
\text{vec}\left[T^{-1/2} \sum_{t=1}^T \mathcal{T}_y\Lambda \varepsilon_t(\tilde{z}^{\Pi}_{t,3})'(\tilde{z}^{\Pi}_{t,3}, \tilde{z}^{\Pi}_{t,3})^{-1}\right] \xrightarrow{d} \text{vec}(Z_r),
$$

$$
\text{vec}\left[T^{-1/2} \sum_{t=1}^T \mathcal{T}_y\Lambda \varepsilon_t(\tilde{z}^{u}_{t,2})'(\tilde{z}^{u}_{t,2}, \tilde{z}^{u}_{t,2})^{-1}\right] \xrightarrow{d} \text{vec}(Z_u),
$$

where $\tilde{z}^{\Pi}_{t,3} := \tilde{z}_{t,3} - (\tilde{z}_{t,3}, \tilde{z}^{u}_{t,2})(\tilde{z}^{u}_{t,2}, \tilde{z}^{u}_{t,2})^{-1}\tilde{z}^{u}_{t,2}$. $W$ denotes the Brownian motion corresponding to $(\varepsilon_t)_{t \in \mathbb{N}}$ and $W_z = \tilde{z}_{t,1:2}(1)W, W_u = \tilde{z}_{t,1:2}(1)W, W^\Pi_z = W_z - \int W_zW_u'(\int W_uW_u')^{-1}W_u$. Further $\text{vec}(Z_r)$ and $\text{vec}(Z_u)$ are normally distributed with mean zero (vec denotes columnwise vectorisation). Finally $\tilde{c}_{z,1:2}(1) := [\tilde{c}_{z,1}(1)', \tilde{c}_{z,2}(1)']'$.

The next theorem, which is the main contribution of this paper, extends these results to the RRR estimators:
Theorem 3.2 (I) Let the assumptions of Theorem 3.1 hold. Then \( \hat{\beta}_{RRR} - b = O((\log T)^6/\sqrt{T}). \) Furthermore let \( \hat{\beta}_{RRR,r} \) and \( \hat{\beta}_{OLS,r} \) denote the coefficients corresponding to \( z_t^r \). Then the asymptotic distribution of \( \hat{\beta}_{RRR,r} \) can be found from

\[
[T_y(\hat{\beta}_{RRR,r} - \hat{\beta}_{OLS,r})T_{z,r}^{-1}D_{z,r}^{-1} \xrightarrow{d} \left[ \begin{array}{c} -\Xi \\ I \end{array} \right] (I - \tilde{O}_2\tilde{O}_2^\dagger)M_{r,2} \left[ -Y_{11}^{-1}I \right] \left[ (I - \tilde{O}_2\tilde{O}_2^\dagger)\tilde{Z}_{r,2}P \right] ]
\]

where

\[
\Xi = -[0,1,0]^T \bar{\gamma}_2(\bar{\gamma}_2^\circ)^{-1}, \\
M_{r,2} = f([0,1]^T A W_{y,2} W_{y,1} - Y_{11}^{-1} W_{y,1}), \\
Y_{11} = \int W_{y,1}^T W_{y,1}^\dagger, i = 1, 2, \\
P = I - \tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ + \tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ = (\Gamma_{3,2}^\circ \tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ)^{-1}\tilde{\gamma}_2^\circ, \\
\tilde{b}_{3,2} = \tilde{O}_2\tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ = (\tilde{O}_2(\tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ)^{-1}\tilde{O}_2)^{-1}\tilde{O}_2(\tilde{\gamma}_2^\circ \tilde{\gamma}_2^\circ)^{-1}.
\]

Here \( \tilde{Z}_{r,2} = [0,1]^T Z_r, W_{y,2} = [(W_{y,1}^\circ)^\dagger, (W_{y,1}^\circ)^\circ]^\circ \) and \( \tilde{\gamma}_{3,3} = \tilde{\gamma}_{3,3} - \tilde{\gamma}_{3,3}(\tilde{\gamma}_{3,2}^\circ (\tilde{\gamma}_{3,2}^\circ)^{-1}\tilde{\gamma}_{3,2}^\circ)^{-1}\tilde{\gamma}_{3,2}^\circ \) and \( \tilde{\gamma}_{3,2}^\circ \) is defined analogously. Finally \( \hat{R} \) is defined in Lemma A.9. Correspondingly letting \( \hat{\beta}_{RRR,u} \) and \( \hat{\beta}_{OLS,u} \) denote the coefficients corresponding to \( z_t^u \) then

\[
[T_y(\hat{\beta}_{RRR,u} - \hat{\beta}_{OLS,u})T_{z,u}^{-1}D_{z,u}^{-1} \xrightarrow{d} -T_y(\hat{\beta}_{RRR,z} - \hat{\beta}_{OLS,z})T_{z,u}^{-1}D_{z,u}^{-1} \left[ \begin{array}{c} N_r \\ 0 \end{array} \right] \left[ \begin{array}{c} 0 \\ \tilde{\gamma}_{3,3}(\tilde{\gamma}_{3,2}^\circ (\tilde{\gamma}_{3,2}^\circ)^{-1}\tilde{\gamma}_{3,2}^\circ)^{-1} \end{array} \right] + o_P(1).
\]

(II) All results hold true in the situation that all observations are demeaned or detrended prior to estimation, if a.s. rates are replaced with in probability rates, the Brownian motions are replaced by their corresponding demeaned or detrended version and if additionally to the assumptions above the condition \( \sum_{j=1}^\infty j^a\|C_j\| < \infty \) holds for some \( a > 3. \)

Note that the decomposition of \( \tilde{b}_{2,3} \) is not specified. The asymptotic distribution does not depend on the actual choice.

The theorem shows how the inclusion of the rank constraint affects the estimation error which is given as a sum of the error for the unrestricted estimate plus a correction term. All coefficients corresponding to the nonstationary directions in \( z_t \) are estimated \( T \)-consistent and asymptotically the estimation errors have 'matrix unit root' distributions, whereas for directions in which \( (z_t)_{t \in \mathbb{N}} \) is stationary the coefficients are only \( \sqrt{T} \) consistent and the errors are asymptotically normal. The proof of this theorem is given in Appendix A. Note that the larger bounds in the almost sure convergence rates for the restricted estimator reflects
only the techniques of proof used and not the accuracy of the estimators which is more appropriately represented in the distributional results. I.e. the larger bounds for the rank restricted estimator mirrors our inability to prove the tighter bounds rather than the relative accuracy of the estimators.

In the fully modified case conditions for consistency and the asymptotic distribution of the unrestricted estimator is provided in (Phillips, 1995): Under the assumptions on the kernel provided in Assumptions K one obtains:

\[ T_y(\hat{\beta}^+_{OLS} - b)T_z^{-1}D_z^{-1} \xrightarrow{d} \left[ M_r^+ Z_r \quad M_u^+ - M_r^+ N_r \quad Z_u - Z_rE\tilde{z}_{t,3}(\tilde{z}_{t,2}')'(E\tilde{z}_{t,2}(\tilde{z}_{t,2}'))^{-1} \right] \]

where

\[
B = \Lambda W - \Omega_{u,\Delta z}(\Omega_{\Delta z,\Delta z}^{-1})^{-1} \left[ \tilde{c}_{z,1,2}(1)W \right], \\
M_r^+ = f(B, W^\Pi), \\
M_u^+ = f(B, \tilde{c}_{z,2}(1)W).
\]

Here the superscript \( n \) refers to the nonstationary directions in \( [\tilde{z}_t', (\tilde{z}_t^u)']' \) and the matrices \( \Omega_{u,\Delta z}^{n,n} \) and \( \Omega_{\Delta z,\Delta z}^{n,n} \) are composed of the respective columns and rows corresponding to the nonstationary components.

The next theorem discusses the properties of the corresponding rank restricted estimator:

**Theorem 3.3** Let the assumptions of Theorem 3.2 hold and additionally assume that a kernel function fulfilling assumptions K is used in the nonparametric estimation of the long run variances. Let \( \tilde{\beta}^+_{RRR} \) denote the FM-RRR estimator (based on the fully modified estimator \( \tilde{\beta}^+_{OLS} \)) defined in (5) for the weight \( \tilde{\Xi} \) as defined in (4). Then using the notation of Theorem 3.2 it holds that

\[
[T_y(\tilde{\beta}^+_{RRR,r} - \tilde{\beta}^+_{OLS,r})T_{z,r}^{-1}]D_{z,r}^{-1} \xrightarrow{d} \left[ \begin{array}{c} \Xi \\ I \end{array} \right] (I - \hat{O}_2\hat{O}_2) M_2^+ \left[ \begin{array}{c} -Y_2 Y_2^{-1} \\ I \end{array} \right] \left[ \begin{array}{c} \tilde{R} \\ (I - \hat{O}_2\hat{O}_2)\tilde{Z}_{r,2} P \end{array} \right].
\]

where \( M_2^+ = f([0, I]T_yAB, W^\Pi_{z,2} - Y_2 Y_2^{-1}W^\Pi_{z,1}). \)

Therefore the relation between the restricted and the unrestricted regressions are identical for the conventional and the fully modified case. Also the expressions for the two sets of estimators are identical except for the use of \( W \) in the conventional case which is replaced by \( B \) in the fully modified case. Therefore it follows that the distribution in the direction of (asymptotically) stationary components of \( w_t \) is identical for both estimators. Hence in
the case that \( c_z = 0 \) and therefore no integration is present the conventional and the fully modified estimators have the same asymptotic distribution. This is true for the restricted and the unrestricted estimates. We refrain from a more complete discussion on the properties of the fully modified estimator since for the unrestricted case these are well documented in the literature. Instead a number of special cases will be discussed below.

4 Special Cases

First consider the case where all included variables are stationary. In that case \( T_y = I, T_z = I \) can be used and the asymptotic distribution of the vectorizations of \( \sqrt{T}(\hat{\beta}_{OLS} - b) \) and \( \sqrt{T}(\hat{\beta}^+_{OLS} - b) \) are both normal with mean zero and variance \( (Ez_tz_t' - 1) \otimes \Lambda \Sigma \Lambda' \) which equals the distribution of

\[
\text{vec} \left( [Z_r, Z_u - Z_rE\tilde{z}_{t,3}T(\tilde{z}_{t,2})'(E\tilde{z}_{t,2}(\tilde{z}_{t,2})')^{-1}] \right)
\]

noting that in this case \( \tilde{z}_t = \tilde{z}_{t,3} = z_t^r, \tilde{z}_{t,2} = z_t^u \) can be chosen. The correction due to the rank restriction for \( \beta_r \) equals the vectorization of

\[
-(I - \hat{O}_2\hat{O}_2^\dagger)Z_r(I - E\tilde{z}_{t,3}(\tilde{z}_{t,3})\Gamma_{32}\Gamma_{32}^\dagger).
\]

The corresponding correction to \( b_u \) follows. On total hence one obtains as the asymptotic distribution of the RRR-estimator for \( b_r \) the distribution of \( Z_r - (I - \hat{O}_2\hat{O}_2^\dagger)Z_r(I - E\tilde{z}_{t,3}(\tilde{z}_{t,3})\Gamma_{32}\Gamma_{32}^\dagger). \)

This asymptotic distribution (for a generic case) has previously been documented in (Reinsel and Velu, 1998) on p. 45 (2.36) albeit in a different form which is less accessible. On p. 46 a more explicit expression for the case \( n = 1 \) is given. It is straightforward to see that the expressions in this special case are identical while the formula provided above also provide insights in the general case. It must be noted, however, that these expressions are not new and have been used already e.g. in (Bauer, Deistler and Scherrer, 1999).

The consequences of the correction using the rank restriction are the following: Premultiplying the asymptotic distribution with \( \hat{O}_2^\dagger \) one notices that the rank restriction does not influence the distribution in these directions. In the orthogonal complement, however, the distribution is changed from \( x'Z_r \) to \( x'Z_rE\tilde{z}_{t,3}(\tilde{z}_{t,3})\Gamma_{32}\Gamma_{32}^\dagger \) and hence projected onto the rows corresponding to the space spanned by the columns of \( \Gamma_{32} \). The analogous statements hold
for the postmultiplication with $\Gamma_{32}$. Note that these arguments also hold in the general case for the (2, 3) block of $\tilde{b}_r$.

As a second special case consider the VAR(1) I(1) model of Anderson (2002). For simplicity of notation the transformed system will be used which in the notation of Anderson (2002) is stated as

$$
\Delta X_t = \Upsilon X_{t-1} + W_t = \begin{bmatrix} 0_{c_y \times c_y} & 0 \\ 0 & \Upsilon_{22} \end{bmatrix} X_{t-1} + W_t, \ t \in \mathbb{N}
$$

(6)

for $X_0 = 0$ where $\Upsilon_{22}$ is nonsingular. This defines an I(1) process $X_t \in \mathbb{R}^s$ whose first component, $X_{t,1} \in \mathbb{R}^{c_y}$ say, is integrated, the remaining, $X_{t,2} \in \mathbb{R}^{s-c_y}$ say, being stationary for $|\lambda_{max}(I+\Upsilon_{22})| < 1$ which is assumed in the following. The variance of the iid white noise $W_t$ is taken to be $[\Sigma_{ij}^{W}]_{i,j=1,2}$ which is partitioned according to the partitioning of $X_t$. In our notation no transformation matrices are needed since the system is already in the appropriate coordinate system. Hence $y_t = \tilde{y}_{t,2} = \Delta X_t$ is stationary, $z_{t,2} = X_{t-1,1}$, $z_{t,3} = X_{t-1,2}$, $z_{t}^u$ does not occur. Consequently $\tilde{b}_r = \Upsilon = [\Upsilon_{1,1}, \Upsilon_{1,2}]$ and $b_u$ does not occur.

In this situation (Anderson, 2002) gives the asymptotic distribution of the unrestricted and the restricted estimates of $\Upsilon$. Consider first $\Upsilon_{1,1}$, i.e. the first block column. Then Theorem 1 of (Anderson, 2002) states that $T\tilde{\Upsilon}_{1,1,\text{OLS}} \xrightarrow{d} J_{2,1}I_{11}^{-1}$ which in our notation equals $f(W, W_1)$ where $W$ is the Brownian motion according to $u_t = W_t$ and $W_1$ denotes the corresponding first block. For $\tilde{\beta}_{RRR,r}$ (Anderson, 2002) states the asymptotic distribution of the first block column as

$$
T\tilde{\Upsilon}_{1,1,\text{RRR}} \xrightarrow{d} \begin{bmatrix} 0 \\ J_{2,1}I_{11}^{-1} \end{bmatrix}, J_{2,1} = [-\Sigma_{WW}^{21}(\Sigma_{WW}^{11})^{-1}, I]J_{1,1}.
$$

From Theorem 3.2 we obtain

$$
T\tilde{\beta}_{1,\text{RRR}} = T\tilde{\beta}_{1,\text{OLS}} + T(\tilde{\beta}_{1,\text{RRR}} - \tilde{\beta}_{1,\text{OLS}}) \xrightarrow{d} f(W, W_1) - (I - \tilde{O}_2\tilde{\Omega}_2^1)f(W, W_1) = \tilde{O}_2\tilde{\Omega}_2^1J_{1,1}I_{11}^{-1}.
$$

The second block column of $\tilde{b}_r$ provides the decomposition $\tilde{O}_2 := [0, I]', \Gamma_{32} := \Upsilon_{22}$. Here $\tilde{O}_2\tilde{\Omega}_2^1 = [0, I]'([0, I]\Sigma_{y2,y2}^{-1}[0, I]')^{-1}[0, I]\Sigma_{y2,y2}^{-1}$ where

$$
\Sigma_{y2,y2}^{-1} = \begin{bmatrix} \Sigma_{WW}^{11} & \Sigma_{WW}^{12} \\ \Sigma_{WW}^{21} & \Sigma_{WW}^{22} \end{bmatrix}^{-1} = \begin{bmatrix} (\Sigma_{WW}^{11})^{-1} & \Sigma_{WW}^{12} \\ 0 & I \end{bmatrix} + \begin{bmatrix} -\Sigma_{WW}^{11} & \Sigma_{WW}^{12} \\ 0 & I \end{bmatrix}(Q - \Sigma_{WW}^{21}(\Sigma_{WW}^{11})^{-1}\Sigma_{WW}^{12})^{-1}[\Sigma_{WW}^{21}(\Sigma_{WW}^{11})^{-1}, I]
$$

(for some matrix $Q$) according to the block matrix inversion. Thus $\tilde{O}_2\tilde{\Omega}_2^1 = [0, I]'[-\Sigma_{WW}^{21}(\Sigma_{WW}^{11})^{-1}, I]$ showing the identity of the expressions.
For the FM estimator note that the involved long run covariances equal

\[ \Omega_{u,\Delta z}^n = \Sigma_{WW}^{\Delta z}, \quad \Omega_{\Delta z,\Delta z}^n = \Sigma_{WW}^{11} \]

with all other terms being zero. Correspondingly

\[ \Omega_{u,\Delta z}^n(\Omega_{\Delta z,\Delta z}^n)^{-1} = [I, (\Sigma_{WW}^{11})^{-1}\Sigma_{WW}^{12}]' \Rightarrow J_{21}I_{11}^{-1} = f(B, W). \]

Thus it follows that the coefficients to the nonstationary regressors for the FM-estimator have the same asymptotic distribution as the RRR estimators. Adding the rank restriction in this case does not change the asymptotic distribution while it might well influence the finite sample properties. It is straightforward to show that in this case also the RRR-FM estimator has the same distribution for the columns corresponding to the integrated regressors.

With respect to the stationary directions it is easy to see that \( P = 0 \) since \( \Gamma_{32} = \Upsilon_{22} \) is invertible. Consequently the RRR estimator and the OLS estimator have the same asymptotic distribution in the columns corresponding to the stationary regressors. Since FM and OLS estimators have the same asymptotic behavior for stationary regressors all four estimators show the same asymptotic behavior in these columns. The underlying reason for this is that the rank restriction exclusively applies to the nonstationary restrictions where the corresponding coefficient is restricted to zero. For the stationary regressors there are no other rank restrictions in this case.

Adding additional lagged first differences to (6) the AR(p) setting with transformed coordinates is obtained. The additional coefficients are not restricted (except for the seldom imposed restriction of stability of the corresponding transfer function) and hence in this case

\[ z_t^u = \tilde{z}_{t,2}^u = [\Delta X_{t-1}', \ldots, \Delta X_{t-p+1}'], \text{ i.e. additional stationary regressors are present.} \]

It is well known that in this case (using the usual notation such that \( \Upsilon = \alpha'\beta' \) where \( \alpha'_{\perp}\alpha = 0, \beta'_{\perp}\beta = 0 \) for orthogonal matrices \( \alpha_{\perp}, \beta_{\perp} \) of maximal dimension such that the columns span the orthogonal complement of \( \alpha, \beta \) respectively) we have

\[ X_t = \beta_{\perp}(\Gamma_J)^{-1} \left( \alpha'_{\perp} \sum_{j=1}^{t-1} \varepsilon_{t-j} + X_1 \right) + w_t, \tag{7} \]

for some stationary process \( w_t \) and nonsingular matrix \( \Gamma_J \) (expressions could be given but are not of importance in the following and hence omitted). In the example \( \alpha' = [0, \Upsilon_{22}'], \beta' = [0, I] \) and thus \( \alpha'_{\perp} = [I, 0], \beta_{\perp} = [I, 0]' \).
The changes in the asymptotic distribution are the following: $W$ is unchanged while $W_z = \Gamma_J^{-1}W_1$. The stationary components change accordingly. Imposing the rank restriction (as is done in the Johansen quasi-ML estimators) does not change the asymptotic distribution of the coefficients corresponding to the stationary terms as in the AR(1) case presented above since $\Gamma_{32}$ again is nonsingular and hence $P = 0$. Thus we obtain the same asymptotic distribution as in the non-restricted case. This asymptotic distribution is also given in Theorem 13.5. of (Johansen, 1995).

For the coefficients corresponding to nonstationary coordinates we obtain analogously to above

$$T\tilde{\beta}_{1,RRR} = T\tilde{\beta}_{1,OLS} + T(\tilde{\beta}_{1,RRR} - \tilde{\beta}_{1,OLS}) \overset{d}{\rightarrow} \tilde{O}_2\tilde{O}_2^t f(W, W_z) = \begin{bmatrix} 0 \\ I \end{bmatrix} [-\Sigma_{WW}^{11}(\Sigma_{WW}^{11})^{-1}, I] f(W, W_z).$$

For the FM estimator note that the involved long run covariances equal

$$\Omega_{u,\Delta z}^{n,n} = \Sigma_{WW}^{11}(\Gamma_J^{-1})', \Omega_{\Delta z,\Delta z}^{n,n} = \Gamma_J^{-1}\Sigma_{WW}^{11}(\Gamma_J^{-1})'$$
due to the change in the nonstationary directions. Then $\Omega_{u,\Delta z}^{n,n}(\Omega_{\Delta z,\Delta z}^{n,n})^{-1} = [I, (\Sigma_{WW}^{11})^{-1}\Sigma_{WW}^{12}(\Gamma_J^{-1})']$ as above implies that again the unrestricted FM estimator has the same asymptotic distribution as the RRR estimator. This is remarkable since the FM estimator does not require the specification of the rank restriction. This has already been observed in (Phillips, 1995) but apparently did not draw the attention of the community.

5 Conclusions

In this paper the asymptotic properties for two estimators in a regression setting explicitly imposing a rank restriction are discussed. Beside providing (almost sure) rates of convergence also explicit expressions for the asymptotic distribution of transformed estimators (such that stationary and nonstationary coordinates are separated) are provided. These expressions reveal the main characteristics of the estimators and allow insights into the relative merits of the various methods such as the gain in asymptotic accuracy obtained by imposing the rank restriction. In particular it is shown that the fully modified estimators in many situations achieve the same asymptotic distribution as the rank restricted regression OLS estimators without imposing the rank restriction. This is an attractive feature in situations where the rank is not known.
The results contain a number of well known situations as special cases and even in some of these cases allow new insights as the previously published expressions for the asymptotic distribution are much more complicated to interpret.

Finally it must be noted that the results in this paper are seen to be intermediate results that might in many cases not seem to be relevant as they relate to transformed estimators where the transformations are not known during the estimation. Nevertheless, the results are important ingredients to explore the properties of procedures that use the RRR as an intermediate step. An important example are subspace methods in the case of cointegrated processes. These results will be presented elsewhere.

### A Proofs

Throughout the appendix the following notation will be heavily used: For a sequence of random matrices $F_T$ with elements $F_{i,j,T}$ and a sequence of scalars $g_T$ we will use the notation $F_T = o(g_T)$ if $\limsup_{T \to \infty} \max_{i,j} |F_{i,j,T}/g_T| \to 0$ almost surely (a.s.). Similarly $F_T = O(g_T)$ if there exists a constant $M$ such that $\limsup_{T \to \infty} \max_{i,j} |F_{i,j,T}/g_T| \leq M$ a.s. The corresponding in probability versions are: $F_T = o_P(g_T)$ if $\max_{i,j} |F_{i,j,T}/g_T| \to 0$ in probability and $F_T = O_P(g_T)$ if for each $\varepsilon > 0$ there exists a constant $M(\varepsilon) < \infty$ such that $\lim_{T \to \infty} P\{\max_{i,j} |F_{i,j,T}/g_T| > M(\varepsilon)\} < \varepsilon$. In all these statements $T$ denotes the sample size. Therefore in particular convergence in distribution to a finite dimensional almost surely finite random variable implies the rate $O_P(1)$. Throughout convergence in probability will be denoted as $\xrightarrow{p}$ and convergence in distribution as $\xrightarrow{d}$. Almost sure (a.s.) convergence
is denoted as →. ∥·∥ denotes the Euclidean norm if not stated explicitly otherwise. ∥·∥Fr is used to denote the Frobenius norm. As usual the integral \( \int W_1 W_2' d\omega \) is short notation for \( \int_0^1 W_1(\omega) W_2(\omega)' d\omega \) and \( \int dW_1 W_2' \) is short for \( \int_0^1 dW_1(\omega) W_2(\omega)' \). Here \( W_1(\omega) \) and \( W_2(\omega) \) are two Brownian motions on \([0,1]\).

A.1 Preliminary lemmas

**Lemma A.1** (I) Let \((\varepsilon_t)_{t \in \mathbb{Z}}\) denote a white noise sequence which fulfills the noise assumptions contained in Assumption P. Define \( x_{t,1} := \sum_{j=1}^{t-1} \varepsilon_j, t \geq 2, x_1 = 0, v_t := c_o(L) \varepsilon_t := \sum_{i=1}^{\infty} C_{v,i} \varepsilon_{t-i}, t \in \mathbb{N}, \) for some transfer function \( c_o(z) := \sum_{j=1}^{\infty} C_{v,j} z^j \) where \( \sum_{j=1}^{\infty} \| C_{v,j} \| j^a < \infty \) for some \( a > 3/2 \). Furthermore \( n_t := \sum_{j=0}^{t-1} C_{n,j} x_{t-j,1}, t \in \mathbb{N}, \) for a sequence \( C_{n,j} \) such that \( \sum_{j=0}^{\infty} \| C_{n,j} \| j^a < \infty, a > 3/2 \) and for \( c_n(z) = \sum_{j=0}^{\infty} C_{n,j} z^j \) it holds that \( \det c_n(1) \neq 0 \). Finally let \( Q_T := \sqrt{\log \log T / T} \). Then

\[
\| (v_t, \varepsilon_t) \| = O(Q_T), \quad \| (v_t, v_t) - E v_t \varepsilon_t^\prime \| = O(Q_T), \\
\langle x_{t,1}, x_{t,1} \rangle = O(T \log \log T), \quad \langle x_{t,1}, \varepsilon_t \rangle = O(\log T), \\
\| (x_{t,1}, v_t) \| = O(\log T), \quad \langle x_{t,1}, x_{t,1} \rangle^{-1} = O(Q_T^2).
\]

All expressions remain true if \( x_{t,1} \) is replaced by \( n_t \).

(II) Furthermore using \( \Delta_{v,\Delta n} = \sum_{j=0}^{\infty} E v_j(\Delta n_0)' \) where \( \Delta n_t = c_o(L) \varepsilon_t, t \in \mathbb{Z} \) we have:

\[
\langle v_t, n_t \rangle \xrightarrow{d} \int c_o(1) dW W' c_n(1)' + \Delta_{v,\Delta n}, \\
T^{-1} \langle n_t, n_t \rangle \xrightarrow{d} c_n(1) \int W W' c_n(1)', \\
vec(T^{-1/2} \langle \varepsilon_t, v_t \rangle) \xrightarrow{d} \mathcal{N}(0, E v_t v_t' \otimes E \varepsilon_t \varepsilon_t')
\]

where \( \vec \) denotes column wise vectorization, \( W(w) \) denotes the limiting Brownian motion corresponding to \( T^{-1/2} \sum_{j=1}^{[wT]} \varepsilon_j \). Finally \( \mathcal{N}(0, V) \) denotes a Gaussian random variable with mean zero and variance \( V \).

(III) Let \( x_t := [x_{t,1}', x_{t,1}]' \) where \((x_{t,1})_{t \in \mathbb{N}}\) fulfills the same restrictions as \((v_t)_{t \in \mathbb{N}}\) under (I) and \((x_{t,1})_{t \in \mathbb{N}}\) and \((n_t)_{t \in \mathbb{N}}\) are integrated and of the same form as \((n_t)_{t \in \mathbb{N}}\) under (I). Further let \((v_t)_{t \in \mathbb{N}}\) and \((w_t)_{t \in \mathbb{N}}\) be two stationary processes fulfilling the assumption of \((v_t)_{t \in \mathbb{N}}\) under (I). Let \((\varepsilon_t)_{t \in \mathbb{Z}}\) be as under (I). Let \( n \) denote the residuals of a regression onto \( x_t \) and let \( \Pi \) denote the corresponding limits (whenever the symbol is used the limit exists). Hence e.g.

\[
v_t^\pi = v_t - \langle v_t, x_t \rangle (x_t, x_t)^{-1} x_t. \quad \text{Then}
\]

\[
\langle \varepsilon_t, v_t^\pi \rangle = \langle \varepsilon_t, v_t^\Pi \rangle + O(T^{-1/2}) = O(Q_T),
\]
\[
\langle \varepsilon_t, n_t^* \rangle = \langle \varepsilon_t, n_t \rangle - \langle \varepsilon_t, x_{t,1} \rangle \langle x_{t,1}, x_{t,1} \rangle^{-1} \langle x_{t,1}, n_t \rangle + o(1) = O(\log T(\log \log T)^2),
\]
\[
\langle v_t^\pi, w_t^\pi \rangle = \langle v_t^\pi, w_t^\pi \rangle + O(Q_T) = O(1),
\]
\[
\langle v_t^\pi, n_t^\pi \rangle = O(\log T(\log \log T)^2),
\]
\[
\langle n_t^\pi, n_t^\pi \rangle = \langle n_t, n_t \rangle - \langle n_t, x_{t,1} \rangle \langle x_{t,1}, x_{t,1} \rangle^{-1} \langle x_{t,1}, n_t \rangle + o(T) = O(T(\log \log T)).
\]

(IV) Let \( d_t := [1, t]' \) and \( D_d := \text{diag}(1, T^{-1}) \). For any process \( (a_t)_{t \in \mathbb{N}} \) let \( \bar{a}_t \) denote the detrended process \( \bar{a}_t := a_t - \langle a_t, d_t \rangle \langle d_t, d_t \rangle^{-1} d_t \). Let \( v_t = \sum_{j=0}^\infty C_{v, j} \varepsilon_{t-j} \) where \( \sum_{j=0}^\infty j^2 \| C_{v, j} \| < \infty \). Then \( \| \langle \bar{v}_t, \bar{v}_t \rangle - \mathbb{E}v_t v_t' \| = O_P(Q_T) \). Further for \( (x_t)_{t \in \mathbb{N}} \) as in (I) it follows that \( \langle \bar{\varepsilon}_t, \bar{x}_t \rangle = O_P(1), \langle \bar{v}_t, \bar{x}_t \rangle = O_P(1) \). The same holds for replacing \( x_t \) with \( n_t := \sum_{j=0}^{t-1} C_{n, j} x_{t-j} \) if \( \sum_{j=0}^\infty \| C_{n, j} \|^3 < \infty \).

The following limit theorems hold:
\[
\langle \bar{\varepsilon}_t, \bar{x}_t \rangle \overset{d}{\to} \int dWW', \quad T^{-1} \langle \bar{x}_t, \bar{x}_t \rangle \overset{d}{\to} \int \tilde{W} W'
\]
where \( \tilde{W} := W - (\int W(s)ds)(4 - 6\omega) - (\int sW(s)ds)(12\omega - 6) \) denotes the demeaned and detrended Brownian motion associated with \( (\varepsilon_t)_{t \in \mathbb{N}} \).

The analogous results also holds for the demeaned series \( \bar{a}_t := a_t - \langle a_t, 1 \rangle \) where \( \bar{W} := W - (\int W(s)ds) \) appears in the asymptotic distributions.

**Proof:** (I) \( \langle v_t, \varepsilon_t \rangle = O(Q_T) \) and \( \langle v_t, v_t \rangle - \mathbb{E}v_t v_t' = O(Q_T) \) follow from Theorem 7.4.3 of Hannan and Deistler (1988). \( \langle x_t, x_t \rangle = O(T \log \log T) \) follows from Theorem 3 of Lai and Wei (1983), \( \langle x_t, \varepsilon_t \rangle = o(\log T) \) from Corollary 2 of Lai and Wei (1982). Both results only deal with the univariate case but the extension to the multivariate situation is obvious. This result also implies \( \langle x_t, v_t \rangle = O(\log T) \) (see Bauer, 2009, Lemma 4). The same result applies for \( n_t \) in place of \( x_t \) by splitting \( n_t = c_n(1)x_t + n_t^* \) (Beveridge-Nelson decomposition, see e.g. Phillips and Solo, 1992) where
\[
n_t^* = n_t - c_n(1)x_t = \sum_{j=0}^{t-1} C_{n, j} x_{t-j} - \sum_{j=0}^{t-1} C_{n, j} x_t = (C_{n, 0} - c_n(1))x_t + \sum_{j=1}^{t-1} C_{n, j} x_{t-j}
\]
\[
= (C_{n, 0} - c_n(1))\varepsilon_t + (C_{n, 0} - c_n(1))x_{t-1} + \sum_{j=1}^{t-1} C_{n, j} x_{t-j}
\]
\[
= (C_{n, 0} - c_n(1))\varepsilon_t + (C_{n, 0} + C_{n, 1} - c_n(1))(\varepsilon_{t-1} + x_{t-2}) + \sum_{j=2}^{t-1} C_{n, j} x_{t-j}
\]
\[
= \sum_{j=0}^{t-1} C_{n, j}^* \varepsilon_{t-j}
\]
where $C_{n,t}^* := -\sum_{j=i+1}^{\infty} C_{n,j}$. Due to the summability assumptions on $C_{n,j}$ the transfer function $c_n^*(z) := \sum_{i=0}^{\infty} C_{n,i}^* z^i$ fulfills the properties of Theorem 7.4.3. of Hannan and Deistler (1988). The result then follows from the assumed non-singularity of $c_n(1)$.

The univariate version of $\langle x_t, x_t \rangle^{-1} = O(Q_T^2)$ is contained in Lai and Wei (1982, p. 163). The multivariate version is showed in Bauer (2009).

(II) Since $\sum_{t=1}^{[wT]} \varepsilon_t /\sqrt{T} \Rightarrow W(w)$ (Davidson, 1994, Theorem 27.17) the convergence of $\langle v_t, n_t \rangle$ e.g. given in Park and Phillips (1988, Lemma 2.1. (e)). The result for $T^{-1}\langle n_t, n_t \rangle$ is stated in part (c) of the same lemma. The central limit theorem is standard (cf. e.g. Hannan and Deistler, 1988, Lemma 4.3.4.) since $(\varepsilon_t)_{t \in \mathbb{N}}$ is an ergodic square integrable martingale difference sequence.

(III) The proof is based on the block matrix inversion formula

$$
\begin{bmatrix}
  A & B \\
  C & D
\end{bmatrix}^{-1} = \begin{bmatrix}
  A^{-1} & 0 \\
  0 & 0
\end{bmatrix} + \begin{bmatrix}
  -A^{-1}B \\
  I
\end{bmatrix} (D - CA^{-1}B)^{-1} \begin{bmatrix}
  -CA^{-1} \\
  I
\end{bmatrix}
$$

applied to $\langle x_t, x_t \rangle$. As an example consider

$$
\langle \varepsilon_t, v_t^\tau \rangle = \langle \varepsilon_t, v_t \rangle - \langle \varepsilon_t, x_t \rangle \langle x_t, x_t \rangle^{-1} \langle x_t, v_t \rangle = \langle \varepsilon_t, v_t \rangle - \langle \varepsilon_t, x_t \rangle \langle x_t, v_t \rangle - \langle \varepsilon_t, x_{t-1} \rangle \langle x_{t-1}, x_{t-1} \rangle^{-1} \langle x_{t-1}, v_t \rangle
$$

where $x_{t-1} := x_{t-1} - \langle x_{t-1}, x_t \rangle x_t$. Therefore $\langle x_{t-1}, x_{t-1} \rangle = \langle x_t, x_t \rangle - O(\log T)O(1)O(\log T)$ and $\langle x_{t-1}, v_t \rangle = \langle x_t, v_t \rangle - O(\log T) = O(\log T)$ by (I). Thus

$$
\langle \varepsilon_t, v_t^\tau \rangle = \langle \varepsilon_t, v_t \rangle - \langle \varepsilon_t, x_t \rangle \langle x_t, v_t \rangle - o(\log T)^3 / T) = \langle \varepsilon_t, v_t \rangle - \langle \varepsilon_t, x_t \rangle (\mathbb{E}x_t) x_t^{-1} \mathbb{E}x_t v_t + o(T^{-1/2})
$$

since $\langle \varepsilon_t, x_t \rangle = O(Q_T)$ and $(\mathbb{E}x_t x_t^{-1})^{-1} \mathbb{E}x_t v_t - \langle x_t, x_t \rangle^{-1} \langle x_t, v_t \rangle = O(Q_T)$ as required. For $\langle v_t^\tau, v_t^\tau \rangle$ the same arguments apply with the exception that now $\langle v_t, v_t \rangle = O(1)$ rather than $O(Q_T)$ leading to the second claim. The other claims follow in a similar manner from the bounds achieved under (I).

(IV) Only the results for detrending are shown, the analogous statements for the demeaned series are obvious from the given results. The derivations here use Lemma 1, p. 121 of Sims, Stock and Watson (1990). Lemma 1 (g) shows that $\langle v_t, d_t \rangle D_d = O_P(T^{1/2})$ for stationary $(v_t)_{t \in \mathbb{N}}$ and $\langle x_t, d_t \rangle D_d = O_P(T^{1/2})$ for integrated $(x_t)_{t \in \mathbb{N}}$.

For $\langle \varepsilon_t, x_t \rangle = \langle \varepsilon_t, x_t \rangle - \langle \varepsilon_t, d_t \rangle \langle d_t, x_t \rangle^{-1} \langle d_t, x_t \rangle$ note that the first term converges in distribution according to (II). For the second term note that $\sqrt{T} \langle \varepsilon_t, d_t \rangle D_{d} \xrightarrow{d} \int dW, \int \omega dW \rangle, D_{d}(d_t, d_t) D_{d}$ converges to a constant nonsingular matrix and $T^{-1/2}D_d(x_t, x_t) \xrightarrow{d} \int W, \int \omega W \rangle$. The last two statements follow from Lemma 1 (a) and (c) of Sims et al. (1990). Therefore

$$
\langle \varepsilon_t, x_t \rangle \xrightarrow{d} \int dWW' - \int dW, \int \omega dW \rangle \left[ \int \frac{1}{\omega} \int \omega \right]^{-1} \left[ \int \omega W \right].
$$
This shows that the Brownian motion in the limiting expression is demeaned and detrended.

If $\varepsilon_t$ is replaced by $v_t$ convergence in distribution still holds, but the limits change.

The evaluations for $T^{-1} \langle \bar{x}_t, \bar{x}_t \rangle$ follow the same lines and are omitted.

Decomposing $n_t = c_n(1)x_t + n_t^*$ as above shows that in the above calculations $x_t$ can be replaced with $n_t$ without changing the orders of convergence.

Finally if the time trend is omitted and only demeaning is performed the results can be shown analogously using the arguments given above. □

**Lemma A.2** Under the assumptions of Theorem 3.3 the following holds true:

$$
\hat{\Omega}_{n,\Delta z}^{-1} = \left[ \Omega_{n,\Delta z}(\Omega_{n,\Delta z}^{-1} + o_P(1))^{-1} + O_P(1) \right],
$$

$$
\langle \Delta \hat{z}_t, \hat{z}_t \rangle - \langle \Delta z_{\Delta z, \Delta z} \rangle = \left[ \int dB \left[ \frac{\hat{c}_z}{\hat{c}_z u(1)} W + o_P(1) \right] \right],
$$

$$
\Delta \hat{u}_{n,\Delta z} = \left[ \Delta u_{n,\Delta z} + O_P((K/T)^{1/2}) \right],
$$

$$
\langle \Delta \hat{z}_t, u_t \rangle - \langle \Delta z_{\Delta z, \Delta u} \rangle = \left[ \frac{O_P(K^{-2}) + O_P(1/\sqrt{KT})}{O_P(K^{-2})} \right],
$$

where $B =$

Here the notation refers to the transformed vectors $\hat{z}_t = [(\hat{z}_{t,1})', (\hat{z}_{t,2})', (\hat{z}_{t,3})', (\hat{z}_{t,4})']'$ where the nonstationary components of both vectors (first block row) and the stationary components (second block row) of these vectors are separated. $K$ denotes the kernel bandwidth parameter (see Assumptions K). Furthermore $\Delta_{u,\Delta u} = \hat{\Xi}_w v_t$ for stationary processes $(v_t)_{t \in \mathbb{Z}}$ and $(w_t)_{t \in \mathbb{Z}}$.

The proof of all but the last of these facts can be found in Phillips (1995, Lemma 8.1). The last fact can be easily derived from the infinite sum representation of $\Delta_{\Delta z, \Delta u}$.

**Lemma A.3** Let $b_r = O' \Sigma_p$ where $G' S_p = I_{n}$. Here $S_p \in \mathbb{R}^{m_r \times n}$ denotes a selector matrix (i.e. a matrix composed of $n$ columns of $I_{m_r}$). Let $\hat{\beta}_r$ denote an estimator of $b_r$ such that $\|\hat{\beta}_r - b_r\|_{F_r} = o(a_T)$.

Assume that $\|\Delta_+ - \Xi_+\|_{F_r} = o(T^{-\epsilon})$ and $\|\Delta_- - \Xi_-\|_{F_r} = o(T^{-\epsilon})$ ($\Xi_+$ and $\Xi_-$ being nonsingular) for some $\epsilon > 0$ and let $\hat{\Xi}_+ \hat{\Delta} \hat{\Sigma}_- \hat{\Xi}_- = b_r$ be obtained as the best (in Frobenius norm) rank $n$ approximation of $\Xi_+ \hat{\beta}_r \Xi_-$.

Further let $O^\dagger := (O'(\Xi_+)^2 O)^{-1} O'(\Xi_+)^2$ assuming that $\|(O'(\Xi_+)^2 O)^{-1}\| < \infty$. 

Then for $T$ large enough $\hat{G}$ can a.s. be chosen such that $\hat{G}'S_p = I_n$. Further
\begin{equation}
\hat{G}' - G' = O^\dagger(\hat{\beta}_r - b_r)(I_p - S_pG') + o(a_T).
\end{equation}

**Proof:** Since $\|\hat{\beta}_r - b_r\|_{F^r} = o(a_T)$ it follows from the boundedness assumption on $O^\dagger$ that $O^\dagger\hat{\beta}_r, S_p \to O^\dagger\beta_r, S_p = I_n$. Since $\hat{O}\hat{G}'$ is a best approximation to $b_r$ based on $\hat{\beta}_r$ in a weighted least squares sense it follows that

$$
\|\hat{O}\hat{G}' - b_r\|_{F^r} \leq \|\hat{O}\hat{G}' - \hat{\beta}_r\|_{F^r} + \|\hat{\beta}_r - b_r\|_{F^r} = O(\|\hat{\beta}_r - b_r\|_{F^r}) = o(1).
$$

It follows that $O^\dagger\hat{O}\hat{G}'S_p \to O^\dagger b_r, S_p = I_n$. Therefore $\hat{G}$ subject to the restriction $\hat{G}'S_p = I_n$ is well defined a.s. for $T$ large enough. It follows that $\|(\hat{O}\hat{G}' - b_r)S_p\|_{F^r} = \|\hat{O} - O\|_{F^r} = o(1)$. Letting $\hat{O} := (\hat{O}'(\Xi^+)^2\hat{O})^{-1}\hat{O}'(\Xi^+)^2$ one obtains
\begin{equation}
\hat{G}' - G' = \hat{O}^\dagger \hat{\beta}_r - O^\dagger b_r = (\hat{O}^\dagger - O^\dagger)\hat{\beta}_r + O^\dagger(\hat{\beta}_r - b_r).
\end{equation}

Then $\|\hat{O} - O\| = o(1)$ and $\|\Xi^+ - \Xi^+\| = o(T^{-\epsilon})$ together with the bounds on the norms $\|(O'(\Xi^+)^2O)^{-1}\|$, $\|\Xi^+\|$ and $\|O\|_{F^r}$ imply $\|O^\dagger - \hat{O}\|_{F^r} = o(1)$. Using the fact that $(\hat{G}' - G')S_p = 0$ and $b_r(I - S_pG') = 0$ one obtains
\begin{equation}
\hat{G}' - G' = O^\dagger(\hat{\beta}_r - b_r)(I - S_pG') + (\hat{O}^\dagger - O^\dagger)(\hat{\beta}_r - b_r)(I - S_pG')
\end{equation}

which proves the lemma. \(\square\)

**Lemma A.4** Let $A_T = A_T' = A_0 + \delta^A$, $A_0 = A_0'$ and $B_T = B_0 + \delta^B$ be two sequences of matrices $A_T \in \mathbb{R}^{a \times a}$ and $B_T \in \mathbb{R}^{a \times b}$. $A_0$ and $B_0$ are possibly random matrices. Assume that all matrices are partitioned as
\begin{align*}
A_T &= \begin{bmatrix}
A_{T,11} & A_{T,12} \\
A_{T,21} & A_{T,22}
\end{bmatrix} = \begin{bmatrix}
A_{0,11} + \delta_{11}^A & \delta_{12}^A \\
\delta_{21}^A & A_{0,22} + \delta_{22}^A
\end{bmatrix} = \begin{bmatrix}
A_{0,11} + O_P(a_T^2) & O_P(a_T) \\
O_P(a_T) & A_{0,22} + O_P(a_T)
\end{bmatrix}, \\
B_T &= \begin{bmatrix}
B_{T,11} & B_{T,12} \\
B_{T,21} & B_{T,22}
\end{bmatrix} = \begin{bmatrix}
B_{0,11} + \delta_{11}^B & \delta_{12}^B \\
\delta_{21}^B & B_{0,22} + \delta_{22}^B
\end{bmatrix} = \begin{bmatrix}
B_{0,11} + O_P(b_T^2) & O_P(b_T) \\
O_P(b_T) & B_{0,22} + O_P(b_T)
\end{bmatrix},
\end{align*}

such that $A_{T,11} \in \mathbb{R}^{c \times c}, B_{T,11} \in \mathbb{R}^{c \times c}$ and all other matrices have the corresponding dimensions. The subscripts for all matrices indicate the corresponding blocks. Assume that $A_{0,11}^{-1} = O_P(1), A_{0,22}^{-1} = O_P(1)$. Finally let $J_T := B_T'(A_T)^{-1}B_T - B_0'(A_0)^{-1}B_0$. 

Then if \( a_T \) and \( b_T \) are such that \( a_T \to 0, b_T \to 0 \) we have

\[
J_{T,11} = (\delta_{21}^B)'A_{0,11}^{-1}B_{0,11} + B_{0,11}'A_{0,11}^{-1}\delta_{11}^R - B_{0,11}'A_{0,11}^{-1}\delta_{11}^A - B_{0,11}'A_{0,11}^{-1}\delta_{11}^A \equiv 0 \\
+ \left[(\delta_{21}^B)' - B_{0,11}'A_{0,11}^{-1}\delta_{12}^A\right]A_{0,22}^{-1}\delta_{21}^B - \delta_{21}^A A_{0,11}^{-1}B_{0,11} + o_p(a_T^2 + b_T^2)
\]

\[
J_{T,21} = (\delta_{22}^B)'A_{0,11}^{-1}B_{0,11} + [B_{0,22} + \delta_{22}^B]A_{0,22}^{-1}\delta_{21}^B - \delta_{21}^A A_{0,11}^{-1}B_{0,11} + o_p(a_T^2 + b_T^2)
\]

\[
J_{T,22} = (\delta_{22}^B)'A_{0,11}^{-1}\delta_{12}^A - \delta_{22}^A A_{0,11}^{-1}\delta_{12}^B
\]

Therefore \( J_{T,11} = O_p(a_T^2 + b_T^2) \) and \( J_{T,12} = O_p(a_T + b_T) \), \( J_{T,22} = O_p(a_T + b_T) \). All evaluations hold if all in probability statements are exchanged by almost sure convergence.

**Proof:** The proof follows from straightforward algebraic manipulations using the block matrix inversion

\[
A_T^{-1} = \begin{bmatrix}
A_{T,11}^{-1} & 0 \\
0 & 0
\end{bmatrix} + \begin{bmatrix}
- A_{T,11}^{-1} A_{T,12} \\
I
\end{bmatrix} \left( A_{T,22} - A_{T,21} A_{T,11}^{-1} A_{T,12} \right)^{-1} \left[ - A_{T,21} A_{T,11}^{-1} I \right] (10)
\]

noting that

\[
A_{T,11} = (A_{0,11} + \delta_{11}^A)^{-1} = A_{0,11}^{-1} - A_{0,11} \delta_{11}^A A_{0,11}^{-1} + o_p(a_T^2)
\]

since \( a_T \to 0 \) and \( A_{0,11}^{-1} = O_p(1) \) by assumption. Similarly

\[
\left( A_{T,22} - A_{T,21} A_{T,11}^{-1} A_{T,12} \right)^{-1} = A_{0,22}^{-1} - A_{0,22}^{-1} \left( \delta_{22}^A - \delta_{22}^A A_{0,11}^{-1} \delta_{12}^A - \delta_{22}^A A_{0,11}^{-1} \delta_{12}^A \right) A_{0,22}^{-1} + o_p(a_T^2)
\]

follows. The remaining calculations are tedious but straightforward and hence omitted. \( \square \)

**Lemma A.5** Define the two generalized eigenvalue problems:

\[
(a) \quad \tilde{Q} \tilde{G} = \tilde{M} \tilde{R}^2, \quad (b) \quad \tilde{\Phi} \tilde{\Gamma} = \tilde{\Psi} \tilde{\Theta}^2.
\]

where \( \tilde{G} \in \mathbb{R}^{m \times n}, \tilde{\Gamma} \in \mathbb{R}^{m \times n}, \tilde{R}^2 \in \mathbb{R}^{n \times n}, \tilde{\Theta} \in \mathbb{R}^{n \times n}. \) Further \( \tilde{\Psi} \) and \( \tilde{\Theta} \) are assumed to be nonsingular a.s. and \( \tilde{\Theta} \) is diagonal.

(I) If \( J := \tilde{Q} - \tilde{\Phi} = O(a_T) \) and \( \delta_{zz} := \tilde{M} - \tilde{\Psi} = O(b_T) \) (where \( a_T \to 0, b_T \to 0 \) for \( T \to \infty \)) then there exists matrices \( \tilde{G} \) and \( \tilde{R} \) solving the eigenvalue problem (a) and matrices \( \tilde{\Gamma} \) and \( \tilde{\Theta} \).
solving (b) such that $\Gamma^p S_p = I_n$ (where $S_p$ denotes a selector matrix, i.e. a matrix consisting of columns of the identity matrix), $G - \Gamma = O(a_T + b_T), \bar{R} - \bar{\Theta} = O(a_T + b_T)$.  

(II) Further let $\delta G := \bar{G} - \bar{\Gamma}$. Then the following two equations hold ($\bar{\Gamma} := (\bar{\Gamma}^T \bar{\Psi} \bar{\Gamma})^{-1} \bar{\Gamma}^T$):

$$\bar{\Phi} \delta G - \bar{\Psi} \delta G \bar{R}^2 = \delta_{zz} \bar{G} \bar{R}^2 + \bar{\Psi} \bar{\Gamma} (\bar{R}^2 - \bar{\Theta}^2) - J \bar{G},$$

$$\left( I_m - \bar{\Psi} \bar{\Gamma}^T \right) \delta G \bar{R}^2 = \left( I_m - \bar{\Psi} \bar{\Gamma}^T \right) \left[ J \bar{G} - \delta_{zz} \bar{G} \bar{R}^2 + \bar{\Phi} \delta G \right]$$

(III) By transforming $\hat{G} = \bar{G} S_p (S_p^T \bar{G})^{-1}$ it follows that $\hat{G}$ solves the generalized eigenvalue problem (a) with matrix $\bar{R}^2 = (S_p^T \bar{G}) \bar{R}^2 (S_p^T \bar{G})^{-1}$. Then $\hat{G} - \hat{\Gamma} = O(a_T + b_T), \hat{R} - \hat{\Theta} = O(a_T + b_T)$. Here $\hat{R}$ is not necessarily block diagonal.

**Proof:** Solutions to the generalized eigenvalue problem are not identified. If all eigenvalues are distinct then fixing the sign of one nonzero entry in each column of $\bar{\Gamma}$ results in a unique solution (see e.g. Bauer et al., 1999, p. 1246, for a discussion). If there are repeated eigenvalues then more restrictions need to be introduced in order to achieve identification. It follows from operator theory (cf. e.g. Chatelin, 1983) that there exist normalizations such that the solution to the eigenvalue problem depends analytically on the matrix which is decomposed, i.e. such that $G - \Gamma = o(1)$ a.s. In these normalizations $\bar{R}^2$ is not necessarily diagonal while still being block diagonal where the blocks correspond to the identical eigenvalues in $\Theta$.

In particular let the sequence of matrices $M_T \rightarrow M_0$. Let $\varphi_i$ denote the matrix whose columns span the eigenspaces of $M_T$ corresponding to the eigenvalues $\tilde{\lambda}_j \rightarrow \lambda_{0,i}, j = 1, \ldots, m_i$ where $m_i$ denotes the multiplicity of the eigenvalue $\lambda_{0,i}$ of $M_0$ with corresponding eigenspace spanned by the columns of the matrix $\varphi_{0,i}$. Here it is assumed that the normalization $\varphi_i \varphi_{0,i} = I_{m_i} = \varphi_{0,i} \varphi_{0,i}$ is chosen. Then it holds that

$$\bar{\varphi}_i - \varphi_{0,i} = (\lambda_{0,i} I - M_0)^{\dagger} (M_T - M_0) \varphi_{0,i} + O(\|M_T - M_0\|^2).$$

Here $X^\dagger$ denotes the Moore-Penrose pseudo-inverse. In particular let $M_T = \tilde{M}^{-1} \bar{Q}$ and $M_0 = \bar{\Psi}^{-1} \bar{\Phi}$ and the columns of $G$ and $\Gamma$ equal $\varphi_i$ and $\varphi_{0,i}$ respectively. The condition of nonsingularity for $\bar{\Theta}$ ensures separation from the kernel of $M_0$ and hence correct specification of the size of $\Gamma$. Then let $\bar{\Gamma} := \Gamma (S_p^T \Gamma)^{-1}, \bar{G} := G (S_p^T \Gamma)^{-1}$. Clearly $\bar{\Gamma}$ is a solution to the problem (b) fulfilling the assumption of the Lemma.

The assumptions imply that $M_T - M_0 = O(a_T + b_T)$ showing $G - \Gamma = O(a_T + b_T)$ and consequently $\bar{G} - \bar{\Gamma} = O(a_T + b_T)$. The order of convergence for $\bar{R} - \bar{\Theta}$ then follows from the fact that all other terms in (a) and (b) differ only by this order.
(II) Equation (11) follows from simple algebraic manipulations using the definitional equations (a) and (b) and $\bar{Q} = \bar{\Phi} + J, \bar{M} = \bar{\Psi} + \delta_{zz}, \bar{G} = \bar{\Gamma} + \delta G$. Premultiplying (11) with $\bar{\Gamma}^\dagger$ a rearranging of terms leads to
\[
\bar{R}^2 - \bar{\Theta}^2 = \bar{\Gamma}^\dagger[\bar{\Phi}\delta G - \bar{\Psi}\delta G\bar{R}^2 - \delta_{zz}\bar{G}\bar{R}^2 + J\bar{G}].
\]
Inserting this into (11) shows that
\[
(I_m - \bar{\Psi}\bar{\Gamma}^\dagger)\left[\bar{\Phi}\delta G - \bar{\Psi}\delta G\bar{R}^2 - \delta_{zz}\bar{G}\bar{R}^2 + J\bar{G}\right] = 0.
\]
This shows equation (12).

(III) Follows immediately from (I). □

A.2 Proof of Theorem 3.1

(I) Note that $\mathrm{diag}(\Delta(L)I_{c_y}, I_{m_r - c_r})H^t_r z^t_i = c_y(L)\varepsilon_t$. Consequently the dimension of the cointegrating space of $(z^t_i)_{t \in \mathbb{N}}$ is equal to $m_r - c_r$. The claim on the dimension of the cointegrating space for $(y_t - b_u z^u_t)_{t \in \mathbb{Z}}$ also follows immediately from this representation.

(II) Note that $\tilde{y}_t$ denotes a transformation of $y_t - b_u z^u_t = b_r z^r_t + \Lambda \varepsilon_t$ which equals the estimation equation with the effects of $z^u_t$ removed. Here we use that $H_r$ was defined to be orthogonal. Next it is proved that matrices $\mathcal{T}_y$ and $\mathcal{T}_{z,r}$ transforming the equation into the required form exist.

Let $\mathcal{T}_y \in \mathbb{R}^{s \times s}$ and nonsingular $C \in \mathbb{R}^{c_y \times c_r}$ be chosen such that
\[
\mathcal{T}_y b_r H_r \| C = \begin{bmatrix} I_{c_y} & 0 \\ 0 & 0 \end{bmatrix} \in \mathbb{R}^{s \times c_r}.
\]
It is easy to see that such choices always exist since $c_y$ denotes the rank of $b_r H_r \|$. Then in $\tilde{y}_t := \mathcal{T}_y (y_t - b_u z^u_t) = \mathcal{T}_y (b_r H_r H^t_r z^r_t + \Lambda \varepsilon_t)$ the first $c_y$ coordinates are integrated, the remaining being stationary. Choosing $\mathcal{T}_{z,r} = \mathrm{diag}(C^{-1}, I_{m_r - c_r})H^t_r$ we obtain that the first $c_r$ components of $\mathcal{T}_{z,r} z^r_t$ are integrated, the remaining ones being stationary. Using the above equation we obtain
\[
\mathcal{T}_y b_r \mathcal{T}_{z,r}^{-1} = \begin{bmatrix} I_{c_y} & 0 \\ 0 & \tilde{b}_{r,13} \end{bmatrix}.
\]
Then the choice
\[
\mathcal{T}_{z,r} = \begin{bmatrix} I & 0 & \tilde{b}_{r,13} \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} \mathcal{T}_{z,r}
\]
leads to the required representation. The remaining claims are straightforward to derive. Details are omitted.
A.3 Proof of Theorem 3.2

A.3.1 Consistency

Note that all estimators can be obtained in a two step procedure by first concentrating out \( z^u_t \) and afterwards maximizing the quasi likelihood with respect to \( \beta_r \) (Frisch-Waugh-Lovell equations). For fixed estimate \( \hat{\beta}_r \) the least squares estimator for \( b_u \) is given by 
\[
\hat{\beta}_u = \langle y_t - \hat{\beta}_r z^r_t, z^u_t \rangle (z^u_t, z^u_t)^{-1}.
\]

Therefore
\[
\hat{\beta}_u - b_u = \langle b_r z^r_t + b_u z^u_t + \Lambda \varepsilon_t - \hat{\beta}_r z^r_t - b_u z^u_t, z^u_t \rangle (z^u_t, z^u_t)^{-1} = \langle \Lambda \varepsilon_t, z^u_t \rangle (z^u_t, z^u_t)^{-1} + (b_r - \hat{\beta}_r) (z^u_t, z^u_t) (z^u_t, z^u_t)^{-1}.
\]

This formula applies for the restricted and the unrestricted estimator. For the first term note that

\[
\langle \varepsilon_t, z^u_t \rangle (z^u_t, z^u_t)^{-1} = \langle \varepsilon_t, T_{z,u} z^u_t \rangle (T_{z,u} z^u_t, T_{z,u} z^u_t)^{-1} T_{z,u} = \langle \varepsilon_t, \hat{z}^u_t \rangle (\hat{z}^u_t, \hat{z}^u_t)^{-1} T_{z,u}.
\]

Now (Bauer, 2009) implies that

\[
\langle \varepsilon_t, \hat{z}^u_t \rangle (\hat{z}^u_t, \hat{z}^u_t)^{-1} = [O(P_T), O(Q_T)]
\]

where \( Q_T = \sqrt{\log \log T}/T \) and \( P_T = \sqrt{\log T \log \log T}/T^2 \).

In order to simplify the notation we use the symbols \( \tilde{y}^\pi_t := T_y (y_t - \langle y_t, z^u_t \rangle (z^u_t, z^u_t)^{-1} z^u_t) \) and \( \tilde{z}^\pi_t := T_{z,r} (z^r_t - \langle z^r_t, z^u_t \rangle (z^u_t, z^u_t)^{-1} z^u_t) \) throughout the proof. Here the superscript \( r \) corresponding to \( z^r_t \) will be omitted for notational simplicity. The corresponding symbols \( \tilde{y}^\Pi_{t,i} \) and \( \tilde{z}^\Pi_{t,i} \) denote the corresponding limit (a.s.) for \( T \to \infty \) (where the symbols are only used if the limit exists). In general the residuals of the regression of any variable onto \( z^r_t, t = 1, \ldots, T \) will be denoted using the superscript \( \pi \) and \( \Pi \) will denote the corresponding limit (where it exists).

Using the same result and the Frisch-Waugh-Lovell equations for the first term and the orders of convergence stated in Lemma A.1

\[
\begin{align*}
\langle \tilde{z}_t, \tilde{z}^\pi_t \rangle (\tilde{z}^\pi_t, \tilde{z}^\pi_t)^{-1} &= [O(P_T), O(Q_T)], \\
\langle \tilde{z}_t, \tilde{z}^u_t \rangle (\tilde{z}^u_t, \tilde{z}^u_t)^{-1} &= \langle \tilde{z}_t, \tilde{z}^u_t \rangle \text{diag}(T^{-1}I, I)(\langle \tilde{z}^u_t, \tilde{z}^u_t \rangle \text{diag}(T^{-1}I, I))^{-1} \\
&= \begin{bmatrix} O((\log \log T)^2) & O(T \log \log T)^2) \\ O(1) & O(1) \end{bmatrix}.
\end{align*}
\]

Therefore it is sufficient to show that \( (b_r - \hat{\beta}_r) \) converges to zero. To this end a transformed problem such that all transformed matrices converge to nonrandom matrices is analyzed first.
In this setting it will be possible to provide a.s. bounds for convergence rates. Afterwards the solution to the transformed problem is related to the solutions of the original problem.

Thus consider the transformed problem using the transformation matrices \( \hat{D}_y = \text{diag}(\langle \hat{z}_{t,1}, \hat{z}_{t,1} \rangle^{-1/2}, I) \) and \( \hat{D}_r = \text{diag}(\langle \hat{z}_{t,1}, \hat{z}_{t,1} \rangle)^{-1/2}, I) \) respectively to transform the input and output of the estimated regression according to \( \hat{y}_t = \hat{D}_y \hat{y}_t, \hat{z}_t = \hat{D}_r \hat{z}_t \). The transformed estimator \( \hat{\beta}_r := \hat{D}_y \hat{\beta}_{OLS,r} \hat{D}_r^{-1} \) converges to \( \hat{\beta}_r = \hat{D}_y \hat{\beta}_{OLS,r} \hat{D}_r^{-1} = \hat{D}_y \hat{O}(P_T), \hat{O}(Q_T) | \hat{D}_r^{-1} \)

\[
\begin{bmatrix}
O((\log T)^{3/2}/\sqrt{T}) & O(\log T) \log T\log T / \sqrt{T} \\
O((\log T)^{3/2}/\sqrt{T}) & O(Q_T) \\
\end{bmatrix}
\]}

Adapting the weighting \( \hat{\Xi}_+ := \hat{\Xi}_+ \hat{D}_y^{-1} \) we obtain \( \hat{\Xi}_+ = \hat{I}(C_y, (E\hat{y}_{t,2}^2 \hat{y}_{t,2})^{-1/2}) \) and

\( \hat{\Xi}_+ - \Xi_+ = O((\log T) \log T / \sqrt{T}) \) as needed in Lemma A.3. This is obtained using the Cholesky factor as the square root of a matrix which is a differentiable operation. With this new normalization we obtain\(^2\)

\[
\delta \hat{\beta}_r := \hat{\beta}_{OLS,r} - \hat{b}_r = \hat{D}_y (\hat{\beta}_{OLS,r} - \hat{b}_r) \hat{D}_r^{-1} = \hat{D}_y \hat{O}(P_T), \hat{O}(Q_T) | \hat{D}_r^{-1} \\
\begin{bmatrix}
O((\log T)^{3/2}/\sqrt{T}) & O(\log T) \log T\log T / \sqrt{T} \\
O((\log T)^{3/2}/\sqrt{T}) & O(Q_T) \\
\end{bmatrix}
\]}

\[
\hat{\beta}_{RRR,r} - \hat{b}_r = \hat{O}\hat{G}' - \hat{O}\hat{G} = (\hat{O} - \hat{O})\hat{G}' + O(\hat{G}' - \hat{G}') \\
\hat{O} - \hat{O} = (\hat{\beta}_{RRR,r} - \hat{b}_r) S_p, \\
\hat{G}' - \hat{G}' = O(\hat{\beta}_{OLS,r} - \hat{b}_r) (I - S_p \hat{G}') + (\hat{O}^\dagger - \hat{O}^\dagger) (\hat{\beta}_{OLS,r} - \hat{b}_r) (I - S_p \hat{G}')
\]

where

\[
S_p = \begin{bmatrix}
I & 0 \\
0 & 0 \\
0 & I \\
0 & 0
\end{bmatrix}, G = \begin{bmatrix}
I & 0 \\
0 & 0 \\
0 & \Gamma_{3,2} \\
0 & 0
\end{bmatrix}, I - S_p \hat{G}' = I - \begin{bmatrix}
I & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & \Gamma_{3,2}
\end{bmatrix}.
\]

Here the first two block rows of \( S_p \) correspond to \( \hat{z}_{t,1} \) and \( \hat{z}_{t,2} \). The remaining two blocks correspond to \( \hat{z}_{t,3} \). Since \( \hat{\beta}_{RRR,r} \) is a best rank \( n \) approximation to \( \hat{\beta}_r \) (see the proof of Lemma A.3) the rate of convergence of \( \hat{\beta}_r \) implies that \( \hat{\beta}_{RRR,r} - \hat{b}_r = O((\log T)^{3/2}/\sqrt{T}) \). Consequently also \( \hat{O} - \hat{O} = O((\log T)^{3/2}/\sqrt{T}) \) and hence also \( \hat{O}^\dagger - \hat{O}^\dagger = O((\log T)^{3/2}/\sqrt{T}) \)

where \( \hat{O}^\dagger := \hat{O}' \hat{\Xi}_+^{-2} \hat{O}^{-1} \). This shows the convergence rates for the solutions to the transformed problem. It thus remains to connect the solution to the original problem to the solution of the transformed problem.

It is straightforward to see that the untransformed estimate \( \hat{G}' = (\hat{O}^\dagger \hat{D}_y \hat{\beta}_{OLS,r} S_p)^{-1} \hat{O}^\dagger \hat{D}_y \hat{\beta}_{OLS,r} \) such that \( \hat{G}' S_p = I_n \). According to the limits above

\[
\hat{O}^\dagger \hat{D}_y \hat{\beta}_{OLS,r} \hat{D}_r^{-1} = \hat{O}^\dagger \hat{b}_r + \hat{O}^\dagger (\hat{D}_y \hat{\beta}_{OLS,r} \hat{D}_r^{-1} - \hat{b}_r)
\]

\(^2\)Here and below we will not always use the tightest possible bounds but use powers of \( \log(T) \) instead for readability. Improvements are possible but their practical merits must be doubted.
where we have used that all terms have been shown above to be of order $O((\log T)^{3/2}/\sqrt{T})$.

Further (due to the usage of the SVD and the corresponding orthogonality relations)

\[
\tilde{O} - O = \tilde{O} \tilde{G}' \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger - O = \tilde{\beta}_{OLS,r} \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger - O
\]

\[
= \langle \hat{y}_t, \hat{z}_T \rangle \tilde{G}^\dagger - O = \langle \hat{b}_T \hat{z}_t + \hat{e}_t, \hat{z}_T \rangle \tilde{G}^\dagger - O
\]

\[
= OG' \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger - O + \langle \hat{e}_t, \hat{z}_T \rangle \tilde{G}^\dagger
\]

\[
= OG' \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger - O + O(G' - \tilde{G}') \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger + \langle \hat{e}_t, \hat{z}_T \rangle \tilde{G}^\dagger
\]

\[
= O(G' - \tilde{G}') \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger + \langle \hat{e}_t, \hat{z}_T \rangle \tilde{G}^\dagger
\]

where

\[
\tilde{G}^\dagger := \tilde{G} \tilde{G}' \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G} = \tilde{G} \tilde{D}_n (\tilde{D}_n \tilde{G}' \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G} \tilde{D}_n)^{-1} \tilde{D}_n.
\]

It then follows from the orders of convergence provided in Lemma A.1 that $\tilde{D}_n \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger \tilde{D}_n^{-1} = O(\log T)$. Consequently

\[
[\tilde{G}' - G'] \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger = [O((\log T)^4/T), O((\log T)^4/\sqrt{T})] \tilde{D}_n \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger
\]

\[
= [O((\log T)^6/T), O((\log T)^6/\sqrt{T})].
\]

Furthermore

\[
\langle \hat{e}_T, \hat{z}_T \rangle \tilde{G}^\dagger = \langle \hat{e}_T, \hat{z}_T \rangle \langle \hat{z}_T, \hat{z}_T \rangle^{-1} \tilde{D}_n \langle \hat{z}_T, \hat{z}_T \rangle \tilde{G}^\dagger
\]

\[
= [O(P_T), O(Q_T)] \tilde{D}_n^{-1} O(\log T) \tilde{D}_n
\]

\[
= [O((\log T)^3/T), O((\log T)^3/\sqrt{T})].
\]
Together these orders imply $\tilde{O} - O = [O((\log T)^6/T), O((\log T)^6/\sqrt{T})]$ and thus

$$\tilde{\beta}_{RRR,r} - \tilde{b}_r = (\tilde{O} - O)G' + O(G' - G) = [O((\log T)^6/T), O((\log T)^6/\sqrt{T})].$$

Consequently we obtain from transforming (15)

$$\tilde{\beta}_{RRR,u} - \tilde{b}_u = O((\log T)^6/\sqrt{T}).$$

This shows the convergence rates.

A.3.2 Asymptotic Normality

In order to derive the asymptotic distribution of the estimator $\hat{\beta}_{RRR}$ the proof extends the theory contained in Anderson (2002). Since the proof is rather lengthy, the main steps are documented using lemmas summing up the main intermediate results.

Note that the RRR estimator is obtained from the singular value decomposition (using the symmetric matrix square roots)

$$\langle \tilde{y}_t^\pi, \tilde{y}_t^\pi \rangle^{-1/2} \langle \tilde{y}_t^\pi, \tilde{z}_t^\pi \rangle \langle \tilde{z}_t^\pi, \tilde{z}_t^\pi \rangle^{-1/2} = \hat{U} \hat{R} \hat{V}'.$$

Then as in Anderson (2002) (1.10), p. 205, the reduced rank estimator can be obtained as

$$T_y \hat{\beta}_{RRR, r} T_z^{-1} = \langle \tilde{y}_t^\pi, \tilde{z}_t^\pi \rangle \tilde{G} (\tilde{z}_t^\pi, \tilde{z}_t^\pi) \tilde{G}^{-1} \tilde{G}'$$

where $\tilde{G} = (\tilde{z}_t^\pi, \tilde{z}_t^\pi)^{-1/2} \hat{V}_n T_G \in \mathbb{R}^{m \times n}$ satisfies the following equations

$$\langle \tilde{z}_t^\pi, \tilde{y}_t^\pi \rangle \langle \tilde{y}_t^\pi, \tilde{y}_t^\pi \rangle^{-1} \langle \tilde{y}_t^\pi, \tilde{z}_t^\pi \rangle \tilde{G} = \langle \tilde{z}_t^\pi, \tilde{z}_t^\pi \rangle \tilde{G} (T_G^{-1} \hat{R}^2 T_G)$$

where $\hat{R}^2 = \text{diag}(\hat{r}_1^2, \hat{r}_2^2, \ldots, \hat{r}_n^2)$ denotes the matrix containing the squares of the $n$ largest estimated singular values as its diagonal entries. The function of the transformation matrix $T_G$ will become clear from the following.

Introduce the following notation (where in $D_z$ the subscript $r$ is omitted for notational simplicity):

$$\tilde{D}_z := D_z T^{1/2} = \text{diag}(T^{-1/2} I, I), \quad \tilde{D}_y = D_y T^{1/2} = \text{diag}(T^{-1/2} I, I),$$

$$\tilde{G} := \tilde{D}_z^{-1} \tilde{G},$$

$$\tilde{Q} := \langle \tilde{D}_z \tilde{z}_t^\pi, \tilde{D}_y \tilde{y}_t^\pi \rangle \langle \tilde{D}_y \tilde{y}_t^\pi, \tilde{D}_y \tilde{y}_t^\pi \rangle^{-1} \langle \tilde{D}_y \tilde{y}_t^\pi, \tilde{D}_z \tilde{z}_t^\pi \rangle,$$

$$\tilde{M} := \langle \tilde{D}_z \tilde{z}_t^\pi, \tilde{D}_z \tilde{z}_t^\pi \rangle,$$
A summary of the (unfortunately heavy) notation used can be found in Appendix B. The main guideline of the notation is to use Latin letters for matrices in which the stationary and the nonstationary subproblems are not separated (i.e. the off-diagonal blocks potentially are nonzero) and Greek letters for matrices for the decoupled problems. A bar indicates estimates (appropriately normalized so that convergence holds). This leads to two generalized eigenvalue problems related to SVDs:

\[(a) \quad \tilde{Q} \tilde{G} = \tilde{M} \tilde{G} \tilde{R}^2, \quad (b) \quad \tilde{Φ} \tilde{Γ} = \tilde{Ψ} \tilde{Γ} \tilde{Θ}^2.\]

Hence \(\tilde{G}\) denotes the solution to the original problem (a), \(\tilde{Γ}\) the solution to problem (b) where stationary and nonstationary components are separated. Consequently the solutions to (b) have the form:

\[
\tilde{Γ} = \begin{bmatrix} I & 0 \\ 0 & \Gamma_{3,2} \end{bmatrix} \rightarrow Γ = \begin{bmatrix} I & 0 \\ 0 & \Gamma_{3,2} \end{bmatrix}
\]

where the corresponding SVD for the stationary subproblem of (b) and its limit can be written as

\[
\langle \tilde{z}^n_{3,3}, \tilde{z}^n_{3,3} \rangle \tilde{Υ} \tilde{Θ}_2 = \langle \tilde{z}^n_{3,3}, \tilde{y}^n_{1,2} \rangle (\tilde{y}^n_{1,2}, \tilde{y}^n_{1,2})^{-1} (\tilde{y}^n_{1,2}, \tilde{z}^n_{3,3}) \tilde{Υ},
\]

\[
E^{z}_{3,2}(E^{z}_{3,2})' \tilde{Υ} \tilde{Θ}_2 = E^{z}_{3,2}(E^{z}_{3,2})'(E^{z}_{3,2}(E^{z}_{3,2})')^{-1} E^{z}_{3,2}(E^{z}_{3,2})' \tilde{Υ}.
\]

Solutions to these equation are not unique. In light of Lemma A.3 the restrictions \(\Gamma'_{3,2}S_{p,22} = I = \tilde{Γ}'_{3,2}S_{p,22}\) will be imposed. Here \(S_{p,22}\) is a suitable selector matrix, i.e. a matrix whose columns are columns of an identity matrix. W.r.o.g. it can be assumed that \(S'_{p,22} = [I, 0]\) by using an appropriate transformation \(T_z\). Note that this implies that \(Θ_2\) and \(\tilde{Θ}_2\) are not necessarily diagonal. Let \(S_p = [S_{p,1}, S_{p,2}]\) where \(S'_{p,1} = [I, 0]\) and \(S'_{p,2} = [0, S'_{p,22}]\). Then \(Γ'S_p = I = Γ'T_p\) are sufficient restrictions to identify the solutions \(Γ\) and \(\tilde{Γ}\). Analogously \(\tilde{Γ}'_{3,2}S_{p,22} = I, \tilde{Γ}_{1,1} = I, \tilde{R} = \text{diag}(\tilde{R}_1, \tilde{R}_2)\) identify a solution (asymptotically, see Lemma A.3 and Lemma A.5). These solutions will be used in the following. Here \(\tilde{Θ}_2\) and \(Θ_2\) resp. denote the \((2,2)\) blocks of \(Θ = \text{diag}(I, Θ_2)\) and \(Θ = \text{diag}(I, \tilde{Θ}_2)\) respectively.

The relations between the various solutions to the generalized eigenvalue problem are collected in section B. Throughout the rest of the proof we will use the following notation for
blocks of matrices: For a matrix \( X \) partitioned into blocks we let \( X_{i,j} \) denote the blocks of the matrix. If multiple blocks are included also the notation ‘\( i : j \)’ will be used indicating the matrix built of blocks with indices \( i \) up to (and including) \( j \). In order to denote block rows or columns we use a semicolon for selecting the whole row or column. Hence e.g. \( \bar{G}_{3,2} \) denotes the \((3,2)\) block, \( \bar{G}_{1,\cdot} \) the first block row and \( \bar{G}_{1:2,1} \) the first two blocks rows in the first block column of the matrix \( \bar{G} \).

The next lemma establishes orders of convergence of the solutions to the generalized eigenvalue problems.

**Lemma A.6** Let the assumptions of Theorem 3.2 hold.

(I) Partition the matrices \( \bar{Q}, \bar{M}, \bar{\Phi}, \bar{\Psi} \) according to the partitioning of \( \bar{z}_t \) the various blocks using subscripts. Then

\[
\delta_{zz} := \bar{M} - \bar{\Psi} = \begin{bmatrix}
0 & 0 & O_P(T^{-1/2}) \\
0 & 0 & O_P(T^{-1/2}) \\
O_P(T^{-1/2}) & O_P(T^{-1/2}) & 0
\end{bmatrix},
\]

\[
\delta_{yz} := \begin{bmatrix}
T^{-1}((\langle \bar{y}_{t,1}^T, \bar{z}_{t,1}^T \rangle - \langle \bar{z}_{t,1}^T, \bar{z}_{t,1}^T \rangle) & T^{-1}((\langle \bar{z}_{t,2}^T, \bar{z}_{t,3}^T \rangle - \langle \bar{z}_{t,2}^T, \bar{z}_{t,3}^T \rangle) & T^{-1/2}(\bar{y}_{t,2}^T, \bar{z}_{t,3}^T) \\
\end{bmatrix},
\]

\[
\delta_{yy} := \begin{bmatrix}
T^{-1}((\langle \bar{y}_{t,1}^T, \bar{y}_{t,1}^T \rangle - \langle \bar{z}_{t,1}^T, \bar{z}_{t,1}^T \rangle) & T^{-1/2}(\bar{y}_{t,2}^T, \bar{y}_{t,2}^T) & 0 \\
\end{bmatrix} = \begin{bmatrix}
O_P(T^{-1}) & O_P(T^{-1/2}) & 0 \\
O_P(T^{-1/2}) & O_P(T^{-1/2}) & 0
\end{bmatrix}.
\]

The terms \( O_P(T^{-1}) \) are \( O((\log T)(\log T^2)/T) \) and the \( O(P^{-1/2}) \) terms are \( O((\log T)(\log \log T)^2/T^{-1/2}) \).

(II) Let \( J := \bar{Q} - \bar{\Phi} \). To simplify notation define \( Z_{ij} := T^{-1}(\langle \bar{z}_{i,1}^T, \bar{z}_{j,1}^T \rangle), i, j = 1, 2 \). Then

\[
J_{i,j} = \begin{bmatrix}
[\langle z_{y,y}^T - Z_{11}Z_{11}^{-1}\delta_{y,y} \rangle Z_{11}^{-1}Z_{11} - \delta_{y,y} & \gamma_{12}^T \delta_{y,y} - \delta_{y,y} Z_{11}^{-1} Z_{11} + \gamma_{12}^T \delta_{y,y} - \delta_{y,y} Z_{11}^{-1} Z_{11}] + O_P(T^{-1}), \\
\end{bmatrix}
\]

\[
J_{3,3} = \begin{bmatrix}
(\langle \bar{y}_{t,1}^T, \bar{z}_{t,1}^T \rangle, Z_{11}^{-1} Z_{11} - \delta_{y,y} & \gamma_{12}^T \delta_{y,y} - \delta_{y,y} Z_{11}^{-1} Z_{11} + \gamma_{12}^T \delta_{y,y} - \delta_{y,y} Z_{11}^{-1} Z_{11}] + O_P(T^{-1}), \\
\end{bmatrix}
\]

(17)

for \( i = 1, 2 \) where expressions for the remaining blocks of \( J \) follow from symmetry. Hence \( J_{i,j} = O_P(T^{-1}) \) and indeed \( J_{i,j} = O((\log T)^3/T) \) for \( i, j = 1, 2 \). Further \( J_{3,i} = O_P(T^{-1/2}) \) and indeed \( J_{3,i} = O((\log T^3/T^{-1/2}) \) for \( i = 1, 2 \). \( J_{3,3} = O_P(T^{-1}) \) and \( J_{3,3} = O((\log T)^3/T) \) respectively.

(III) \( \delta G := \bar{G} - \Gamma = O_P(T^{-1/2}) \) and moreover \( \delta G = O((\log T)^3/T^{1/2}) \).

**Proof:** (I) The orders of convergence for the various entries of \( \delta_{zz} \) and \( \delta_{yz} \) follow from Lemma A.1. Details are omitted.
(II) Set \( B_T := \hat{D}_y \langle \hat{y}_{t}^\pi, \hat{z}_{t}^\pi \rangle \hat{D}_z \) and \( A_T := \hat{D}_y \langle \hat{y}_{t}^\pi, \hat{y}_{t}^\pi \rangle \hat{D}_y \) in Lemma A.4 where the partitioning refers to nonstationary and stationary components in the various matrices. Note that for the in probability part \( a_T = b_T = T^{-1/2} \) and for the almost sure convergence \( a_T = b_T = \log T (\log \log T)^2 / T^{-1/2} \) fulfill the assumptions of Lemma A.4. Also note that \( \delta_{22}^A = 0, \delta_{22}^B = 0 \) simplifying the expression for \( J_{3,3} \). Then Lemma A.4 proves this part of the lemma. The orders of convergence for the various entries of \( J \) follow from the equations given and the orders of convergence provided in Lemma A.1. Here also the uniform bound on the two and infinity norm of \( \langle \hat{z}_{i,2}^u, \hat{z}_{i,2}^u \rangle^{-1}, \langle \hat{y}_{i,2}^u, \hat{y}_{i,2}^u \rangle^{-1} \) which are implied by Assumption P are used.

(III) follows from (I) and (II) in combination with Lemma A.5. \( \square \)

The next lemma (proven in section A.4) gathers more detailed results on the asymptotic properties of the entries of \( \delta G \):

**Lemma A.7** Let the assumptions of Theorem 3.1 hold. Then we obtain

\[
\begin{align*}
\delta G_{1,1} &= 0, \\
\delta G_{1,2} &= -Z_{11}^{-1} Z_{12} \delta G_{2,2} + Z_{11}^{-1} [\delta_{22}^{13} \bar{\Gamma}_{3,2} \Theta_2^2 - J_{1,3} \bar{\Gamma}_{3,2} (I - \Theta_2^2)]^{-1} + o(T^{-1/2}), \\
\delta G_{2,1} &= (T^{-1} \langle \bar{z}_{i,2}^\pi, \bar{z}_{i,2}^\pi \rangle)^{-1} [J_{2,1,1} + (J_{2,1,3} - \delta_{zz}^{2,1,3}) \delta G_{3,1}] + o(T^{-1}) = O((\log T)^7 / T), \\
\delta G_{2,2} &= (T^{-1} \langle \bar{z}_{i,2}^\pi, \bar{z}_{i,2}^\pi \rangle)^{-1} [J_{2,1,3} \bar{\Gamma}_{3,2} \Theta_2^2 - \delta_{zz}^{2,1,3} \bar{\Gamma}_{3,2}] + o(T^{-1/2}), \\
\delta G_{3,1} &= \tilde{S} [J_{3,1} - \delta_{zz}^{31}] + o(T^{-1}), \\
\delta G_{3,2} &= o(T^{-1/2}),
\end{align*}
\]  

where \( \bar{z}_{i,2}^\pi = \bar{z}_{i,2} - Z_{21} Z_{11}^{-1} \bar{z}_{i,1} \), \( \delta_{zz}^{2,1,1} = \delta_{zz}^{2,1,1} - Z_{21} Z_{11}^{-1} \delta_{zz}^{11} \), \( J_{2,1,1} = J_{1,1} - Z_{21} Z_{11}^{-1} J_{2,1,1} \), \( \tilde{S} = (Z_{33} - \langle \bar{z}_{i,3}^\pi, \bar{y}_{i,2}^\pi \rangle \langle \bar{y}_{i,2}^\pi, \bar{y}_{i,2}^\pi \rangle^{-1} \langle \bar{y}_{i,2}^\pi, \bar{z}_{i,2}^\pi \rangle)^{-1} \)

using \( Z_{33} = \langle \bar{z}_{i,3}^\pi, \bar{z}_{i,3}^\pi \rangle \) and

\[
\tilde{P}_{3,3} = Z_{33} - Z_{33} \bar{\Gamma}_{3,2} \bar{\Gamma}_{3,2} \bar{\Gamma}_{3,2} Z_{33}.
\]

Next these approximations are linked to the estimate \( \hat{\beta}_{RRR,r} \).

**Lemma A.8** Let the assumptions of Theorem 3.2 hold.

(I) Then

\[
T_y (\hat{\beta}_{RRR,r} - b_r) T_z^{-1} D_z^{-1} = \left[ \sqrt{T} \langle \hat{z}_t, \hat{z}_t^\pi \rangle \hat{D}_z \right] \bar{\Gamma}^{\dagger} + \begin{bmatrix} T I & 0 \\ 0 & \sqrt{T} \bar{O}_2 \end{bmatrix} \delta G' (I - \bar{M} \bar{G} \bar{G}^{\dagger})
\]
\[
\begin{bmatrix}
0 & 0 \\
0 & 0 \\
\sqrt{T}[\tilde{\beta}_{2,3} - \tilde{\beta}_{2,3}] & 0
\end{bmatrix}
\begin{bmatrix}
I - \mathbb{E}z^H_{t,3}(z^H_{t,3})\Gamma_{3,2}\Gamma_{3,2}^\dagger
\end{bmatrix}
+ o_P(1)
\]

where

\[
\tilde{\beta}_{2,3} = \langle \tilde{y}^\pi_{t,2}, \tilde{z}^\pi_{t,3} \rangle \Gamma_{3,2}\Gamma_{3,2}^\dagger = \bar{O}_2 \bar{\Gamma}_{3,2} \rightarrow \hat{O}_2 \Gamma_{3,2} = \tilde{b}_{2,3}
\]
denotes the solution to the subproblem of the problem (b) corresponding to the stationary components. \( \Gamma_{3,2} = (\Gamma_{3,2}^\dagger \mathbb{E}z^H_{t,3}(z^H_{t,3})\Gamma_{3,2})^{-1}\Gamma_{3,2} \).

(II) Letting \( \delta G_{1,1} \) and \( \delta G_{1,2} \) denote the first and second block column of \( \delta G \) it holds that

\[
T\delta G'_{1,1}(I - \bar{Y} \bar{G} \bar{G}^T) = [-T\delta H'Z_{21}Z_{11}^{-1} T\delta H' T\delta G'_{3,1} \bar{P}] + o(1),
\]

\[
\sqrt{T}\delta G'_{1,2}(I - \bar{Y} \bar{G} \bar{G}^T) = \sqrt{T}\delta G'_{2,2} [-Z_{21}Z_{11}^{-1} I 0] + o(1)
\]

where \( \delta H = \delta G_{2,1} - \delta G_{2,2}(\Gamma_{3,2}^\dagger \mathbb{E}z^H_{t,3}(z^H_{t,3})\delta G_{3,1} \).

The term \( o_P(1) \) is also \( O((\log T)^o) \).

Part (I) of the lemma splits the estimation error \( \hat{\beta}_{R_{RR,rr}} - b_r \) (up to errors of higher order) into three terms: The first term asymptotically equals the estimation error in the situation that the row space of \( b_r \) is known and used in the estimation to obtain unrestricted least squares estimators. The second term accounts for the effects of the rank restriction in the nonstationary components of both the output (i.e. \( \tilde{y}^\pi_{t,1} \)) as well as the regressors (i.e. \( \tilde{z}^\pi_{t,i}, i = 1, 2 \)). Part (II) of the lemma provides a more detailed expression for this term. The last term corrects for the rank restriction in the stationary directions.

Up to now only for showing \( \sqrt{T}\delta G'_{3,1}(I - \langle \tilde{z}^\pi_{t,3}, \tilde{z}^\pi_{t,3} \rangle \bar{\Gamma}_{3,2} \bar{\Gamma}_{3,2}^\dagger) \rightarrow 0 \) the exact form of \( \delta_{zz} \) and \( J \) are used. All other results up to now rely only on the order of convergence of these terms. The proof of Theorem 3.2 is completed with the last lemma of this section giving explicit expressions for the asymptotic distributions of the various parts of the expressions for \( T_g(\hat{\beta}_{R_{RR,rr}} - b_r)T_{z,rr}^{-1}D_{z,rr}^{-1} \) given in Lemma A.8. The result then follows directly from (15).

Lemma A.9 With \( \bar{O}_2^\dagger = (\bar{O}_2'(\mathbb{E}y^H_{t,2}(y^H_{t,2})')^{-1}\bar{O}_2(\mathbb{E}y^H_{t,2}(y^H_{t,2})')^{-1} \)
we have

\[
\langle \tilde{\varepsilon}_t, \tilde{z}^\pi_{t,3} \rangle Z_{11}^{-1} \sim f(T_g AW, W_{z,1}^H),
\]

\[
\sqrt{T}\langle \tilde{\varepsilon}_t, \tilde{z}^\pi_{t,3} \rangle \langle \tilde{z}^\pi_{t,3}, \tilde{z}^\pi_{t,3} \rangle^{-1} \sim N(0, V),
\]

\[
\sqrt{T}\delta G_{2,2} = (T^{-1}\langle \tilde{z}^\pi_{t,2,1}, \tilde{z}^\pi_{t,2,1} \rangle)^{-1}\langle \tilde{z}^\pi_{t,2,1}, \tilde{\varepsilon}_t, t=2 \rangle (\bar{O}_2^\dagger)' + o_P(1) \sim M_{t,2}(\hat{O}_2^\dagger)',
\]

\[
T\delta G_{3,1} = Z_{33}^{-1}P\sqrt{T}(\tilde{z}^\pi_{t,3}, \tilde{\varepsilon}_t, t=1) + Z_{33}^{-1}\sqrt{T}(P(\tilde{z}^\pi_{t,3}, \tilde{y}_{t,2}) - P(\mathbb{E}z^H_{t,3}(\tilde{y}^H_{t,2})')\Xi + o_P(1) \sim \bar{R}',
\]

\[
T\delta H = (T^{-1}\langle \tilde{z}^\pi_{t,2,1}, \tilde{z}^\pi_{t,2,1} \rangle)^{-1} \left[ \langle \tilde{z}^\pi_{t,2,1}, \tilde{\varepsilon}_t, t=1 \rangle + \langle \tilde{z}^\pi_{t,2,1}, \tilde{z}^\pi_{t,2} \rangle (I - \bar{O}_2 \hat{O}_2)'\Xi \right] + o_P(1) \sim N',
\]

\[
\sqrt{T}[\tilde{\beta}_{2,3} - \tilde{\beta}_{2,3}] \sim \bar{O}_2 \hat{O}_2^\dagger \sqrt{T}(\tilde{\varepsilon}_t, z^H_{t,3})(\mathbb{E}z^H_{t,3}(z^H_{t,3})')^{-1} \sim P + o_P(1),
\]
where \( P = (I - \mathbb{E}Z_t^{\Pi,I}(z_t^{\Pi,I})^T \Gamma_{3,2}^T)^{-1} \). Further \( Y_{11} = \int W_{z_t}^\Pi (W_{z_t}^\Pi)' \). Here \( M_{r,2} = [0, I]M_r \) with \( M_r := f(T_yAW, W_{z_t}^\Pi) \) where \( W_{z_t} := W_{z_t}^\Pi - Y_{11}^{-1}W_{z_t}^\Pi. \ N = [I, 0] + \Xi(I - \hat{O}_2 \hat{O}_2^\dagger)[0, I] M_r. \)

Combining Lemma A.8 and A.9 we obtain that \( \mathcal{T} \left( \hat{\beta}_{RR}, r - b_r \right) \mathcal{T}_z^{-1} D_z^{-1} \xrightarrow{d} [f(T_yAW, W_{z_t}^\Pi), Z_r]. \)

From this the claim follows using the block matrix inversion since \( \mathcal{T} \left( \hat{\beta}_{OLS}, r - b_r \right) \mathcal{T}_z^{-1} D_z^{-1} \xrightarrow{d} [f(T_yAW, W_{z_t}^\Pi), Z_r]. \)

Using standard asymptotics for the term \( \langle z_t, z_t' \rangle / \langle z_t, z_t' \rangle^{-1} \) we obtain the asymptotic distribution of \( \hat{\beta}_{RR} - \hat{\beta}_{OLS} \) stated in Theorem 3.2 from (15). Note in particular that \( R := Z_{r,1} P - \hat{R} \) where \( Z_{r,1} \) denotes the limit of \( \sqrt{T} \langle \tilde{z}_t, \tilde{z}_t' \rangle Z_{3,3}^{-1} \). This concludes the proof of (I) of Theorem 3.2.

Following the arguments of the proof and using Lemma A.1 (IV) it follows that the usual changes occur if a constant (and a deterministic trend respectively) is included in the regression: The asymptotics in the stationary directions are unchanged. For the nonstationary directions the Brownian motions are replaced by their corresponding demeaned (and detrended respectively) versions. We omit details in this respect.

A.4 Proof of Lemma A.7

In the proof the following results are used: With \( \Xi := -\mathbb{E}\tilde{z}_t, \tilde{y}_t^{\Pi,I} (\tilde{y}_t^{\Pi,I})' \langle \tilde{y}_t^{\Pi,I}, \tilde{y}_t^{\Pi,I} \rangle^{-1}, \tilde{z}_t, 1 = \tilde{z}_t, 2 - Z_{21} Z_{11}^{-1} \tilde{z}_t, 1, J_{2,1,1} = J_{2,1} - Z_{21} Z_{11}^{-1} J_{1,1}, J_{2,1,3} = J_{2,3} - Z_{21} Z_{11}^{-1} J_{1,3} \) and \( \tilde{z}_t, 1, 2 = \tilde{z}_t, 1 + \Xi \tilde{y}_t^{\Pi,I} \), it holds that

\[
\sqrt{T} (\delta_{yz} - \delta_{yy}^{21} / \langle \tilde{y}_t^{\Pi,I}, \tilde{y}_t^{\Pi,I} \rangle) = \Xi + o(1),
\]

\[
\sqrt{T} (J_{3,1} - \delta_{zz}^{31}) = \mathbb{E}\tilde{z}_t, \tilde{y}_t^{\Pi,I} (\tilde{y}_t^{\Pi,I})' \Xi' + o_P(1),
\]

\[
T J_{2,1,1} = \langle \tilde{z}_t, 1, 2, 1, \tilde{z}_t, 1, 2, 1 \rangle + o_P(1),
\]

\[
\sqrt{T} J_{2,1,3} = \langle \tilde{z}_t, 1, 2, 1, \tilde{y}_t^{\Pi,I} \rangle (\mathbb{E} \tilde{y}_t^{\Pi,I} (\tilde{y}_t^{\Pi,I})')^{-1} \hat{O}_2 \Gamma_{3,2}^T Z_{3,3} + o_P(1).
\]

where \( Z_{3,3} := \mathbb{E}\tilde{z}_t, \tilde{y}_t^{\Pi,I} (\tilde{y}_t^{\Pi,I})' \).

The first claim follows from

\[
\sqrt{T} (\delta_{yz} - \delta_{yy}^{21}) = \langle \tilde{y}_t^{\Pi,I}, \tilde{z}_t, 1, 1 - \tilde{y}_t^{\Pi,I} \rangle = -\langle \tilde{y}_t^{\Pi,I}, \tilde{z}_t, 1, 1 \rangle \rightarrow -\mathbb{E}\tilde{z}_t, 2 \tilde{z}_t, 1.
\]
where \( \tilde{y}_{t,2}^\pi = \tilde{\eta}_{t,2} + \tilde{b}_{2,2}(\tilde{\xi}_{t,2} - \langle \tilde{\xi}_{t,2} + \tilde{b}_{2,2}(\tilde{\xi}_{t,3}, \tilde{z}_t^u)\langle \tilde{z}_t^u, \tilde{z}_t^u \rangle^{-1} \tilde{z}_t^u \). Then the result follows straightforwardly since \( \tilde{\xi}_{t,3} \) and \( \tilde{\xi}_{t,1} \) are stationary and uncorrelated by assumption. From this also the second and third claim follow immediately using the expressions for \( J_{1,1} \) derived in Lemma A.7. The fourth claim also follows from these expressions noting that \( \mathbb{E} y_{1,2}^\Pi (\tilde{z}_{t,3})' = \hat{\bar{\Gamma}}_3, z_{t,3}^\Pi (\tilde{z}_{t,3})' \).

Now with respect to the blocks of \( \delta G \) note that due to the chosen normalizations \( \bar{\Gamma}_{1,1} = \bar{G}_{1,1} = I \) implying \( \delta G_{1,1} = 0 \).

Using the order of convergence for \( J, \delta_{zz} \) (Lemma A.6 (I) and (II)) and \( \delta G \) (Lemma A.6 (III)) the (1,2) block of (11) implies

\[
\delta G_{1,2} + Z_{11}^{-1}Z_{12}\delta G_{2,2} = Z_{11}^{-1}[\delta_{zz}^3 \bar{G}_{3,2} \bar{R}_2^2 - J_{1,3} \bar{G}_{3,2}] (I - \bar{R}_2^2)^{-1} + o(T^{-1}).
\]

The expression given then follows from noting that \( \delta_{zz}^3 = O((\log T)^a/T^{1/2}), \bar{G}_{3,2} = \bar{\Gamma}_{3,2} + O((\log T)^3/T^{1/2}), J_{1,3} = O((\log T)^3/T^{1/2}) \) and \( \bar{R}_2^2 = \hat{\Theta}_2^2 + O((\log T)^3/T^{1/2}) \).

The expressions for \( \delta G_{2,1} \) and \( \delta G_{2,2} \) follow from the second block row of equation (12) noting that

\[
(I_m - \bar{\Psi} \bar{\Gamma}^\dagger \bar{\Gamma})' = \begin{bmatrix}
0 & 0 \\
-Z_{21}Z_{11}^{-1}I & 0 \\
0 & I - \bar{\Psi}_{3,3} \bar{\Gamma}_{3,2} (\bar{\Gamma}_{3,2} \bar{\Psi}_{3,3} \bar{\Gamma}_{3,2})^{-1} \bar{\Gamma}_{3,2}
\end{bmatrix},
\]

\[
(I_m - \bar{\Psi} \bar{\Gamma} \Gamma^\dagger) \bar{\Psi} = \begin{bmatrix}
0 & 0 & 0 \\
0 & T^{-1}(\bar{z}_{t,2}^\pi, \bar{z}_{t,2}^\pi) & 0 \\
0 & 0 & \bar{P}_{3,3}
\end{bmatrix}.
\]

Also \( \bar{R}_2^2 - I = O((\log T)^7/T) \) follows from the (1,1) entry of (11). Then the (3,1) entry of equation (11) implies that

\[
\delta G_{3,1} = \bar{S}[J_{3,1} - \delta_{zz}^{31}] + o(T^{-1})
\]

where \( \bar{S}^{-1} \rightarrow S^{-1} \) as

\[
\langle \bar{z}_{t,3}^\pi, \bar{z}_{t,3}^\pi \rangle - \langle \bar{z}_{t,3}^\pi, \bar{y}_{t,2}^\pi \rangle \langle \bar{y}_{t,2}^\pi, \bar{z}_{t,3}^\pi \rangle^{-1} \langle \bar{y}_{t,2}^\pi, \bar{z}_{t,3}^\pi \rangle \rightarrow \mathbb{E} z_{t,3}^\Pi (\bar{z}_{t,3}^\Pi)' - \mathbb{E} z_{t,3}^\Pi (\bar{y}_{t,2}^\Pi)' (\mathbb{E} \bar{y}_{t,2}^\Pi (\bar{y}_{t,2}^\Pi)' - \mathbb{E} \bar{y}_{t,2}^\Pi (\bar{z}_{t,3}^\Pi)' > 0
\]

which is ensured by the assumed nonsingularity of the covariance of \( (\bar{y}_{t,2}^\Pi)' (\bar{z}_{t,3}^\Pi)' \). Further the (3,1) entry in equation (12) directly implies the expression for \( \bar{P}_{3,3} \delta G_{3,1} \) using the orders of convergence derived above. Next

\[
J_{3,1} - \delta_{zz}^{31} = \delta_{zz}^{31} - \delta_{zz}^{31} + \langle \bar{z}_{t,3}^\pi, \bar{y}_{t,2}^\pi \rangle \langle \bar{y}_{t,2}^\pi, \bar{y}_{t,2}^\pi \rangle^{-1} \langle \bar{y}_{t,2}^\pi, \bar{y}_{t,2}^\pi \rangle = T^{-1/2} \langle \bar{z}_{t,3}^\pi, \bar{z}_{t,1}^\pi \rangle + \langle \bar{z}_{t,3}^\pi, \bar{y}_{t,2}^\pi \rangle (\Xi' + o(1))
\]
Note that \( \langle \tilde{z}_{t,3}, \tilde{t}_{1,1} \rangle = O(Q_T), Z_{33}^{-1} \langle \tilde{z}_{t,3}, \tilde{y}_{t,2} \rangle = \Gamma_{3,2} \tilde{O}_2 + O(Q_T), \tilde{P} - P = O((\log T)^3/T^{1/2}) \) and thus
\[
\sqrt{T} P_{3,3} \delta G_{3,1} = \sqrt{T} \tilde{P} (J_{31} - \delta \tilde{z}_{zz}^3) + O(T^{-1/2}) = \tilde{P} \langle \tilde{z}_{t,3}, \tilde{t}_{1,1} \rangle + \tilde{P} \langle \tilde{z}_{t,3}, \tilde{y}_{t,2} \rangle (\Xi + o(1)) + o(T^{-1/2}) = O((\log T)^6/T^{1/2}).
\]

Here the last order follows from \( PE \tilde{z}_{t,3}^H (\tilde{z}_{t,3}^H) \Gamma_{3,2} = 0 \) as is easy to verify.

Since \( \delta G = O((\log T)^3/T^{1/2}) \) also \( \delta G_{1,2} = O((\log T)^3/T^{1/2}) \) and \( \delta G_{2,2} = O((\log T)^3/T^{1/2}) \).

For \( \bar{\Gamma} \) such that \( \bar{\Gamma} \bar{\Gamma} = 0 \) we have that \( \bar{\Gamma} Z_{33}^{-1} \bar{P}_{33} = \bar{\Gamma} \). Then the (3,2) block of (12) shows that
\[
[0, \bar{\Gamma}] \delta G_{3,2} = \bar{\Gamma} \delta G_{3,2} = \bar{\Gamma} Z_{33}^{-1} \bar{P}_{33} \delta G_{3,2} = [0, \bar{\Gamma} Z_{33}^{-1}][JG_{3,2} \bar{R}_2^{-2} - \delta_G G_{3,2}] = o(T^{-1/2})
\]
since the (3,2) block entry of \( JG \) and \( \delta_G G \) both are of order \( o(T^{-1/2}) \) as follows from the norm bounds given for the blocks of \( J \) and \( \delta_G G \).

Due to the chosen normalization \( \bar{\Gamma} S_{p,22} = \bar{G}'_{3,2} S_{p,22} = I \) and thus \( S_{p,22} \delta G_{3,2} = 0 \). Since \( \bar{\Gamma} S_{p,22} \) is nonsingular (as is straightforward to see from \( \bar{\Gamma} = I \) we obtain \( \delta G_{3,2} = o(T^{-1/2}) \).

The order of convergence for \( \delta G_{2,1} \) follows from the orders of convergence of \( J, \delta_G G \) and \( \delta G \) as derived in Lemma A.6.

### A.5 Proof of Lemma A.8

(I) Let \( \tilde{\beta}_{RR, r} = T_y \beta_{RR, r} T_{z, r}^{-1} \) and \( \tilde{b}_r = T_y b_r T_{z, r}^{-1} \). Then
\[
\tilde{\beta}_{RR, r} = \langle \tilde{y}_r, \tilde{z}_r \rangle \tilde{G} \tilde{G}^\dagger = \tilde{b}_r \langle \tilde{z}_r, \tilde{z}_r \rangle \tilde{D}_z \tilde{G} \tilde{G}^\dagger \tilde{D}_z^* + \langle \tilde{t}, \tilde{z}_r \rangle \tilde{D}_z \tilde{G} \tilde{G}^\dagger \tilde{D}_z^{1/2} = \tilde{b}_r \langle \tilde{z}_r, \tilde{z}_r \rangle \tilde{D}_z \tilde{G} \tilde{G}^\dagger \tilde{D}_z^* + \langle \tilde{t}, \tilde{z}_r \rangle \tilde{D}_z \tilde{G} \tilde{G}^\dagger \tilde{D}_z^{1/2} \tilde{G} \tilde{G}^\dagger \tilde{D}_z^{1/2}
\]
where \( \dagger \) stands for equality up to terms of order \( o(T^{-1}) \) in the first \( c_z \) columns and of order \( o(T^{-1/2}) \) in the remaining columns. This follows from \( \langle \tilde{t}, \tilde{z}_r \rangle \tilde{D}_z = O((\log T)^3 T^{-1/2}), \delta G = O((\log T)^3 T^{-1/2}) \) and the definition of \( D_z = \text{diag}(T^{-1} I, T^{-1/2} I) \) showing that \( \tilde{G} \) can be replaced by \( \bar{\Gamma} \) in the second term in the last equation with introduction of an error of the stated order. Now since \( \tilde{b}_r \) is block diagonal
\[
\tilde{b}_r \langle \tilde{z}_r, \tilde{z}_r \rangle \tilde{D}_z \tilde{G} \tilde{G}^\dagger \tilde{D}_z^* = \tilde{D}_y \tilde{D}_z \tilde{G} \tilde{G}^\dagger \tilde{D}_z.
\]

Next note that (using the index ':' to denote block columns or rows resp.) \( \tilde{b}_{r, 1} = [I, 0] = \bar{\Gamma}_{r, 1} \). Therefore we have recalling that \( (\tilde{G}^\dagger)' = \tilde{G}(\tilde{G}' M \tilde{G}^{-1}) \)
\[
[I, 0] = \tilde{G}_{r, 1} M (\tilde{G}^\dagger)' = (\bar{\Gamma}_{r, 1})' M (\tilde{G}^\dagger)' + \delta G_{r, 1} \tilde{M} (\tilde{G}^\dagger)'
\]
\[
= \tilde{b}_{r, 1} (\tilde{G}^\dagger)' + \delta G_{r, 1} \tilde{M} (\tilde{G}^\dagger)'.
\]
This leads to \( \bar{b}_{r,1} : M(G^\dagger)' = [(I, 0) - \delta G_{r,1}' M(G^\dagger)'] \). Hence we obtain

\[
\bar{b}_{r,1} : \langle \tilde{z}^T, \tilde{z}^T \rangle \bar{D}_z \bar{G} \bar{G}^\dagger \bar{D}_z = T^{1/2} [(I, 0) - \delta G_{r,1}' \bar{M}(G^\dagger)'] \bar{G}' \bar{D}_z = \bar{b}_{r,1} + T [\delta G_{r,1}'] [I - M \bar{G} \bar{G}^\dagger] \bar{D}_z.
\]

Here \( \bar{G}_{r,1}' = [I, 0] + \delta G_{r,1}' \) is used in the last line.

With respect to the second block row it follows from \( \bar{b}_{r,2} = [0, \tilde{b}_{2,3}] \) that \( \bar{b}_{r,2} = \bar{b}_{r,2} \bar{D}_z \). Also we have from \( \bar{b}_{2,3} = \bar{O} \bar{G}_{2,2}' \bar{M} \bar{G} \bar{G}^\dagger = \bar{G}_{2,2}' \) by the definition of \( G^\dagger \) that

\[
\bar{b}_{2,3} \langle \tilde{z}^T, \tilde{z}^T \rangle \bar{D}_z \bar{G} \bar{G}^\dagger \bar{D}_z = \bar{O}_2 \bar{G}_{2,2}' \langle \tilde{z}^T, \tilde{z}^T \rangle \bar{D}_z \bar{G} \bar{G}^\dagger \bar{D}_z = \bar{O}_2 \bar{G}_2 \bar{G}_1 [I, 0] - \delta G_{r,2}' \bar{M} \bar{G} \bar{G}^\dagger \bar{D}_z = \bar{O}_2 \bar{G}_2 \bar{G}_1 [I, 0] - \delta G_{r,2}' (I - \bar{M} \bar{G} \bar{G}^\dagger) \bar{D}_z
\]

This implies

\[
\bar{b}_{r,2} : \langle \tilde{z}^T, \tilde{z}^T \rangle \bar{D}_z \bar{G} \bar{G}^\dagger \bar{D}_z = \bar{b}_{r,2} : \bar{D}_z \langle \tilde{z}^T, \tilde{z}^T \rangle \bar{D}_z \bar{G} \bar{G}^\dagger \bar{D}_z = [0, \bar{b}_{2,3} + \bar{O}_2 \delta G_{r,2}'] [I - \bar{M} \bar{G} \bar{G}^\dagger] \bar{D}_z\]

Here the third line follows from the orders of convergence in \( \delta G = G - \bar{G} \) established above and \( \bar{b}_{2,3} - \bar{b}_{2,3} - o(T^{-\epsilon}) \) as follows from standard theory in the stationary case. Then the representation given in (I) is proved by replacing \( \bar{O}_2 \) by its limit \( \bar{O}_2 \) which introduces an error of the required form since \( \bar{O}_2 - \bar{O}_2 = o(T^{-\epsilon}) \) for some \( \epsilon > 0 \) as follows from \( \bar{b}_{2,3} - \bar{b}_{2,3} = o(T^{-\epsilon}) \) (see the proof of Lemma A.3).

(II) For (20) note that \( \delta G \) and \( \bar{M} - \bar{\bar{\Psi}} \) both are of order \( O((\log T)^2 T^{-1/2}) \) and the two norm of \( \bar{\bar{\Psi}} \) and \( \bar{\bar{\Gamma}} \) is of order \( O(\log T) \). Therefore replacing \( \bar{M} \bar{G} \bar{G}^\dagger \) by \( \bar{\bar{\Psi}} \bar{\bar{\Gamma}} \bar{\bar{\Gamma}}^\dagger \) introduces an error of order \( O((\log T)^2 T^{-1/2}) = o(1) \) proving (20) since \( \delta G_{3,2} = o(T^{-1/2}) \) (see Lemma A.7) and

\[
\sqrt{T} \delta G_{r,2}' (I - \bar{\bar{\Psi}} \bar{\bar{\Gamma}} \bar{\bar{\Gamma}}^\dagger) = \sqrt{T} \delta G_{2,2}' \left[ -Z_{21} Z_{11}^{-1} I \ 0 \right] + \sqrt{T} \delta G_{3,2}' \left[ 0 \ 0 \ I - Z_{31} \bar{\bar{G}}_{3,2} \right]
\]

With respect to (19) note that

\[
T \delta G_{r,1}' [I - \bar{M} \bar{G} \bar{G}^\dagger] = T \delta G_{r,1}' \left[ I - \bar{\bar{\Psi}} \bar{\bar{\Gamma}} \bar{\bar{\Gamma}}^\dagger \right] + T \delta G_{r,1}' \left[ \bar{\bar{\Psi}} \bar{\bar{\Gamma}} \bar{\bar{\Gamma}}^\dagger - \bar{M} \bar{G} \bar{G}^\dagger \right]
\]
where

\[ T\delta G'_{1,1}[I - \Psi \tilde{\Gamma} \dot{\Gamma}] = \left[ -T\delta G'_{2,1}Z_{21}Z_{11}^{-1} T\delta G'_{2,1} T\delta G'_{3,1} \tilde{P} \right] \] (21)

is obvious from the form of \( I - \tilde{\Psi} \tilde{\Gamma} \dot{\Gamma} \) (see the proof of Lemma A.7).

Noting that \( \tilde{M} \tilde{G} \dot{G} = \tilde{M} \tilde{G}(\tilde{G}' \tilde{M} \tilde{G})^{-1} \tilde{G}' \) it follows that

\[
\delta G'_{1,1}[\tilde{\Psi} \tilde{\Gamma} \dot{\Gamma} - \tilde{M} \tilde{G} \dot{G}'] = \delta G'_{1,1}\left[ (I - \tilde{\Psi} \tilde{\Gamma} \dot{\Gamma}')(\Psi - M) \Gamma \Gamma' - \tilde{\Psi} \dot{\Gamma} (\Gamma' \tilde{\Psi} \Gamma)^{-1} \delta G'(I - \tilde{\Psi} \tilde{\Gamma} \dot{\Gamma}) \right] - (I - \tilde{\Psi} \tilde{\Gamma} \dot{\Gamma}')\tilde{\Psi} \delta G' + o(T^{-1})
\]

\[
= -\delta G'_{1,1}(\tilde{z}_{3,3}, \tilde{z}_{3,3})\dot{\Gamma}_{3,3}^2(\Gamma_{3,3}^2 - \tilde{z}_{3,3}^2)^{-1} \delta G'_{1,2}(I - \tilde{\Psi} \tilde{\Gamma} \dot{\Gamma}) + o(T^{-1})
\]

since \( \delta G_{1,1} = o(T^{-1}), \delta G_{2,1} = O((\log T)^{T}/T) \) and (see the proof of Lemma A.7 and (17))

\[
\sqrt{T}\delta G'_{3,1}(I - Z_{33} \tilde{\Gamma}_{3,3}^2 \dot{\Gamma}_{3,3}^2) = \sqrt{T}\left[J_{3,1} - \delta_{33}^1 \right]' S(I - Z_{33} \tilde{\Gamma}_{3,3}^2 \dot{\Gamma}_{3,3}^2) + o(T^{-\epsilon})
\]

\[
= [(\tilde{z}_{3,3}, \tilde{z}_{3,3}) + (\tilde{z}_{3,3}', \tilde{y}_{3,3}) \dot{\Xi}]' S(I - Z_{33} \tilde{\Gamma}_{3,3}^2 \dot{\Gamma}_{3,3}^2) + o(T^{-\epsilon})
\]

\[
= o(T^{-\epsilon})
\]

for some \( \epsilon > 0 \) due to \( (\tilde{z}_{3,3}', \tilde{z}_{3,1}) = o(T^{-\epsilon}) \) for \( 0 < \epsilon < 1/2 \) and \( (\tilde{z}_{3,3}, \tilde{y}_{3,2}) \rightarrow E \tilde{z}_{3,3}(\tilde{y}_{3,2})' = E \tilde{z}_{3,3}(\tilde{z}_{3,3})' \Gamma_{3,3}^{3/2} \tilde{O}_{3,2} \). Now \( (\tilde{y}_{3,2}, \tilde{z}_{3,3}) S(I - Z_{33} \tilde{\Gamma}_{3,3}^2 \dot{\Gamma}_{3,3}^2) \rightarrow 0 \) according to

\[ \tilde{S} Z_{33} \tilde{\Gamma}_{3,3}^2 \rightarrow S E \tilde{z}_{3,3}(\tilde{z}_{3,3})' \Gamma_{3,3}^2. \] (22)

Recall that by definition

\[ E \tilde{z}_{3,3}(\tilde{z}_{3,3})' \Gamma_{3,3}^2 \Theta_{3,2}^2 = E \tilde{z}_{3,3}(\tilde{y}_{3,2})' (E \tilde{y}_{3,2}(\tilde{y}_{3,2})')^{-1} \Gamma_{3,3}^2 \tilde{O}_{3,2} \]

Together with the definition of \( S = (E \tilde{z}_{3,3}(\tilde{z}_{3,3})' - E \tilde{z}_{3,3}(\tilde{y}_{3,2})' (E \tilde{y}_{3,2}(\tilde{y}_{3,2})')^{-1} \Gamma_{3,3}^2 \tilde{O}_{3,2} \)

this implies

\[ S E \tilde{z}_{3,3}(\tilde{z}_{3,3})' \tilde{O}_{3,2}^2 = \Gamma_{3,2}(I - \Theta_{3,2}^2)^{1}. \]

Finally \( \sqrt{T}[\delta_{33}^1 - \delta_{33}^{21}](\tilde{y}_{3,2}, \tilde{y}_{3,2})^{-1} = \tilde{\Xi} + o(T^{-\epsilon}) \) is used (as derived above).

Since \( \delta G_{3,2} = o(T^{-1/2-\epsilon}) \) (see Lemma A.7) it follows from the form of \( (I - \tilde{\Psi} \tilde{\Gamma} \dot{\Gamma} \) (see the proof of Lemma A.7) that

\[
T\delta G'_{3,1}[\tilde{\Psi} \tilde{\Gamma} \dot{\Gamma} - \tilde{M} \tilde{G} \dot{G}'] = -\left[ \sqrt{T}\delta G_{3,1} \Gamma_{3,3}^2 \tilde{O}_{3,2} \right] \Gamma_{3,3}^2 \delta G'_{3,2} \right] - Z_{21} Z_{11}^{-1} I, 0 \right] + o(1).
\] (23)

Combining (21) and (23) we obtain

\[
T\delta G'_{1,1}[I - \tilde{M} \tilde{G} \dot{G}'] = T \left[ \delta G'_{2,1} - \delta G'_{3,1} E \tilde{z}_{3,3}(\tilde{z}_{3,3})' \delta G'_{3,2} \right] - Z_{21} Z_{11}^{-1} I, 0 \right] [0 0 T \delta G'_{3,1} \tilde{P} + o(1).
\]

This completes the proof by the definition of \( \delta H \).
A.6 Proof of Lemma A.9

The first claim is standard and follows from Lemma A.1 using \( n_t := [\tilde{z}_{t,1}, (\tilde{z}_{t,1})']' \), \( v_t := T_\theta \Delta \varepsilon_t \) noting that then \( v_t \) is a martingale difference. The second claim is a standard central limit result. Further from Lemma A.7 we have

\[
\sqrt{T} \delta G_{2,2} = (T^{-1}\langle \tilde{z}_{t,2,1}, \tilde{z}_{t,2,1} \rangle)^{-1} \sqrt{T} \left[ J_{t,1,3} \Gamma_{3,2} \Theta_2^{-2} - \delta_{zz}^{2,1,3} \Gamma_{3,2} \right] + o_P(1).
\]

Now from the proof of Lemma A.7

\[
\sqrt{T} J_{t,1,3} \Gamma_{3,2} = \langle \tilde{z}_{t,2,1}, \hat{y}_{t,2} \rangle (\tilde{E} \hat{y}_{t,2} (\hat{y}_{t,2})')^{-1} \hat{O}_2 \Gamma_{3,2} \delta G_{3,3} + o_P(1)
\]

since \( \Theta_2^2 = \hat{O}_2 (\tilde{E} \hat{y}_{t,2} (\hat{y}_{t,2})')^{-1} \hat{O}_2 (\Gamma_{3,2} \delta G_{3,3}) \) as is straightforward to show. This shows the expression for \( \sqrt{T} \delta G_{2,2} \) since \( \hat{O}_2 (\Gamma_{3,2} \delta G_{3,3}) = \langle \tilde{z}_{t,2,1}, \tilde{z}_{t,3} \rangle \).

In order to obtain the expression for \( T \hat{P}' \delta G_{3,1} \) note that from the definition of \( \hat{P}, \hat{P}_3 \) and the arguments in the proof of Lemma A.7

\[
\langle \tilde{z}_{t,3}, \tilde{z}_{t,3} \rangle \hat{P}' \delta G_{3,1} = \hat{P}_3 \delta G_{3,1} = \hat{P} [J_{3,1} - \delta_{zz}^{3,1}] + o(T^{-1}).
\]

Now \( \sqrt{T} [J_{3,1} - \delta_{zz}^{3,1}] \rightarrow \tilde{E} \tilde{z}_{t,3} (\tilde{z}_{t,3})' \Gamma_{3,2} \hat{O}_2 \Xi' \) according to the proof of Lemma A.7 and \( \hat{P} \rightarrow I - \tilde{E} \tilde{z}_{t,3} (\tilde{z}_{t,3})' \Gamma_{3,2} \) where the difference is of order \( O_P(T^{-1/2}) \) since only stationary components are involved. The result then follows from the expression for \( J_{3,1} \) according to Lemma A.6 (II) since

\[
(I - \tilde{E} \tilde{z}_{t,3} (\tilde{z}_{t,3})' \Gamma_{3,2} \hat{O}_2) \tilde{E} \tilde{z}_{t,3} (\tilde{z}_{t,3})' \Gamma_{3,2} \hat{O}_2 \Xi' = 0.
\]

The evaluations for \( \delta H \) are more involved: Using the expressions given in Lemma A.7 and defining \( Z_{22,1} = \langle \tilde{z}_{t,2,1}, \tilde{z}_{t,2,1} \rangle \) we have

\[
\delta H = \delta G_{2,1} - \delta G_{2,2} (\Gamma_{3,2} \delta G_{3,1}) = \sqrt{T} \tilde{E} \tilde{z}_{t,3} (\tilde{z}_{t,3})' \Gamma_{3,2} \hat{O}_2 \Xi' + o_P(T^{-1})
\]

(\( \Gamma_+ := (\Gamma_{3,2} \tilde{E} \tilde{z}_{t,3} (\tilde{z}_{t,3})')' \)) where the last line follows from \( T (J_{2,1,3} - \delta_{zz}^{2,1,3}) (I - \Gamma_{3,2} (\Gamma_{3,2} \delta G_{3,1}) \hat{O}_2 \Xi' = 0 \) in probability since \( \sqrt{T} [J_{2,1,3} - \delta_{zz}^{2,1,3}] \) converges in distribution, \( \sqrt{T} \delta G_{3,1} \rightarrow S \Gamma_{3,2} \hat{O}_2 \Xi' \)
and $SZ_{33}\Gamma_{3,2} = \Gamma_{3,2}(I - \Theta_2^2)^{-1}$ (see (22)). The result then follows from some algebraic operations.

The final statement applies Lemma A.3:

$$\bar{\Gamma}_{3,2}^{'\dagger} - \bar{\Gamma}_{3,2} = \tilde{O}_2(\langle \bar{y}^{\pi}_{t,2}, \bar{z}^{\pi}_{t,3} \rangle (\langle \bar{z}^{\pi}_{t,3}, \bar{z}^{\pi}_{t,3} \rangle)^{-1} - \tilde{\beta}_{2,3})(I - S_{p,22}\Gamma_{3,2}^{'\dagger}) + o(T^{-1/2}). \quad (24)$$

This shows the result since $\tilde{\beta}_{2,3} - \bar{\beta}_{2,3} = (\tilde{O}_2 - \tilde{O}_2)\bar{\Gamma}_{3,2} + \tilde{O}_2(\bar{\Gamma}_{3,2} - \bar{\Gamma}_{3,2}^{'\dagger})$ and $\bar{\Gamma}_{3,2}^{'\dagger}(I - Z_{33}\Gamma_{3,2}^{'\dagger}) \rightarrow 0$. The fact that $(I - S_{p,22}\bar{\Gamma}_{3,2}^{'\dagger})(I - Z_{33}\Gamma_{3,2}^{'\dagger}) = (I - Z_{33}\Gamma_{3,2}\Gamma_{3,2}^{'\dagger})$ simplifies the expressions. This concludes the proof.

### A.7 Proof of Theorem 3.3

The proof follows closely the proof in the OLS case. The changes in comparison to the OLS case are that $\langle y_t, z_t \rangle$ is replaced with

$$\hat{\Sigma}_{y,z} := \langle y_t, z_t^{\pi} \rangle - \hat{\Delta}_{\hat{u},\Delta z^{\pi}} - \hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1}(\langle \Delta z_t, z_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta z^{\pi}}) = \langle y_t, z_t^{\pi} \rangle + \hat{B}^+$$

where hence the additional term is called $\hat{B}^+$ and in the SVD the weighting is not based on $\langle y_t^{\pi}, y_t^{\pi} \rangle$ but on $W_+ = (y_t^{\pi}, y_t^{\pi}) + \hat{C}^+\rangle^{-1}$ where

$$\hat{C}^+ := -\hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1}(\langle \Delta z_t, y_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta y^{\pi}}) - (\langle \Delta z_t, y_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta y^{\pi}}')(\hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1})'.$$

The asymptotics for the additional terms are detailed in the lemma below:

**Lemma A.10** Under the assumptions of Theorem 3.3 the following holds:

$$\hat{\Delta}_{\hat{u},\Delta z^{\pi}} + \hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1}(\langle \Delta z_t, z_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta z^{\pi}}) = \left[ \Omega_{\hat{u},\Delta z}(\Omega_{\Delta z,\Delta z}^{-1}) \int dB_nB_n' + o_P(1) \quad o_P(T^{-1/2}) \right],$$

$$\hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1}(\langle \Delta z_t, y_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta y^{\pi}}) - (\langle \Delta z_t, y_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta y^{\pi}}')(\hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1})'.$$

**PROOF:** The proof of the first statement uses the fact that according to Lemma A.2 $\hat{\Delta}_{\hat{u},\Delta z} = [o_P(1), o_P(T^{-1/2})]$. Here the restrictions on the increase of $K$ as a function of $T$ is used such that we obtain $\sqrt{K/T} = o_P(1), 1/\sqrt{KT} = o_P(T^{-1/2}), K^{-2} = o_P(T^{-1/2})$. Hence it is of lower order compared to the leading terms. Further $\hat{\Omega}_{\hat{u},\Delta z}\hat{\Omega}_{\Delta z,\Delta z}^{-1}(\langle \Delta z_t, z_t \rangle - \hat{\Delta}_{\Delta z,\Delta z}) = [O_P(1), o_P(T^{-1/2})]$ and hence these terms are of the same order as the leading terms. The proof of the second statement is an easy consequence of the results listed in Lemma A.2 using $\tilde{y}_t^{\pi} = \bar{b}_r\tilde{z}_t^{\pi} + \tilde{c}_t^{\pi}$. Note that

$$\langle \Delta z_t, \tilde{y}_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta y^{\pi}} = (\langle \Delta z_t, \tilde{z}_t^{\pi} \rangle - \hat{\Delta}_{\Delta z,\Delta z^{\pi}})\bar{b}'_r + (\langle \Delta z_t, \tilde{u}_t \rangle - \hat{\Delta}_{\Delta z,\Delta u^{\pi}})$$
Convergence for the first summand is contained as the first statement in the lemma, while again following Lemma A.2 we obtain convergence for the second term. □

For both $\hat{\Sigma}_{y,z}$ and $W_+$ after transformation using the matrices $T_y, T_z$ the additional terms in the diagonal blocks are of lower order than the original terms. For the off-diagonal blocks the additional terms are of the same order in probability. This follows from the results in Lemma A.2. However, for the off-diagonal terms in the consistency proof only the order of convergence is used. Consequently the consistency result and the order of convergence (in probability) also hold in the FM case.

In the following we will use the following definitions using the same notation as in the OLS case in order to avoid the introduction of new symbols.

$$Q := \hat{\Sigma}_{y,z} W_+^{-1} \hat{\Sigma}_{y,z},$$

$$M := \langle \hat{D}_z z_{t,1}^\pi, \hat{D}_z z_{t,2}^\pi \rangle,$$

$$\Phi := \begin{bmatrix} T^{-1}(z_{t,1}^\pi, z_{t,1}^\pi) & T^{-1}(z_{t,1}^\pi, z_{t,2}^\pi) & 0 \\ T^{-1}(z_{t,2}^\pi, z_{t,1}^\pi) & T^{-1}(z_{t,2}^\pi, z_{t,2}^\pi)(z_{t,1}^\pi, z_{t,2}^\pi)^{-1}(z_{t,1}^\pi, z_{t,2}^\pi) & 0 \\ 0 & 0 & (z_{t,3}^\pi, y_{t,2}^\pi) \hat{\Sigma}_{y_2,y_2}^{-1} (y_{t,2}^\pi, z_{t,3}^\pi) \end{bmatrix},$$

$$\Psi := \begin{bmatrix} T^{-1}(z_{t,1}^\pi, z_{t,1}^\pi) & T^{-1}(z_{t,1}^\pi, z_{t,2}^\pi) & 0 \\ T^{-1}(z_{t,2}^\pi, z_{t,1}^\pi) & T^{-1}(z_{t,2}^\pi, z_{t,2}^\pi) & 0 \\ 0 & 0 & (z_{t,3}^\pi, z_{t,3}^\pi) \end{bmatrix}.$$  

Here

$$\hat{\Sigma}_{y_2,y_2} := \langle \tilde{y}_{t,2}^\pi, \tilde{y}_{t,2}^\pi \rangle^{-1} \left[ \Omega_{u,z} \Delta_z \Delta_z^{-1} \Omega_{z,\Delta_z}^{-1} (\langle \Delta_z, \tilde{y}_{t,2}^\pi \rangle - \Delta_z \Delta_z \Delta_z^{-1} (\Omega_{u,z} \Delta_z \Delta_z^{-1} (\langle \Delta_z, \tilde{y}_{t,2}^\pi \rangle) - \Delta_z \Delta_z \Delta_z^{-1} (\Omega_{u,z} \Delta_z \Delta_z^{-1} (\langle \Delta_z, \tilde{y}_{t,2}^\pi \rangle) \right) \right] [0, I]^T,$$

such that $\hat{\Sigma}_{y_2,y_2} \to \Sigma_{y_2,y_2} := E \tilde{y}_{t,2}^H \tilde{y}_{t,2}.$

Hence the definition of $Q$ is adapted to the SVD occurring in the FM estimation. Also the (3, 3) entry of $\Phi$ is changed slightly. The reason for this is visible in the next Lemma A.11 which is the analogon to Lemma A.6 for the OLS case.

**Lemma A.11** Let the assumptions of Theorem 3.3 hold.

(I) Partition the matrices $Q, M, \Phi, \Psi$ according to the partitioning of $\tilde{z}_t$ denoting the various blocks using subscripts. Then:

$$\delta_{zz} := \hat{M} - \hat{\Psi} = \begin{bmatrix} 0 & 0 & O_P(T^{-1/2}) \\ 0 & 0 & O_P(T^{-1/2}) \\ O_P(T^{-1/2}) & O_P(T^{-1/2}) & 0 \end{bmatrix},$$

$$\delta_{yz} := \begin{bmatrix} T^{-1}(\tilde{y}_{t,1}^\pi, z_{t,1}^\pi) & T^{-1}(\tilde{y}_{t,1}^\pi, z_{t,2}^\pi) & T^{-1}(\tilde{y}_{t,1}^\pi, z_{t,2}^\pi) \\ T^{-1/2}(\tilde{y}_{t,1}^\pi, z_{t,1}^\pi) & T^{-1/2}(\tilde{y}_{t,2}^\pi, z_{t,2}^\pi) & T^{-1/2}(\tilde{y}_{t,2}^\pi, z_{t,2}^\pi) \end{bmatrix} + \hat{D}_y \hat{B}^+ \hat{D}_z.$$
\[
\begin{align*}
\delta_{yy} & := \tilde{D}_y \left( \langle \tilde{y}_{t,1}^\pi, \tilde{y}_{t,1}^\pi \rangle + \tilde{C}^+ - \begin{bmatrix} \langle \tilde{z}_{t,1}^\pi, \tilde{z}_{t,1}^\pi \rangle & 0 \\ 0 & \hat{\Sigma}_{y2,y2} \end{bmatrix} \right) \tilde{D}_y \\
& = \begin{bmatrix} O_P(T^{-1}) & O_P(T^{-1/2}) & O_P(T^{-1/2}) \\ O_P(T^{-1/2}) & O_P(T^{-1/2}) & o_P(1) \end{bmatrix}.
\end{align*}
\]

(II) Let \( J := \tilde{Q} - \tilde{\Phi} \). To simplify notation define \( Z_{ij} := T^{-1} \langle \tilde{z}_{t,i}^\pi, \tilde{z}_{t,j}^\pi \rangle, i, j = 1, 2 \). Then

\[
\begin{align*}
J_{i,j} &= \left[ \delta_{yy}^{21} - Z_{11}^{-1} \delta_{yy}^{11} \right] Z_{11}^{-1} Z_{1j} + Z_{i1} Z_{11}^{-1} \delta_{yy}^{1j} \\
&\quad + \left[ \delta_{yy}^{22} - Z_{11}^{-1} \delta_{yy}^{12} \right] \Sigma_{y2,y2} \left( \delta_{yy}^{11} - \delta_{yy}^{22} Z_{11}^{-1} Z_{1j} \right) + o_P(T^{-1}), \\
J_{3,i} &= \delta_{yy}^{33} Z_{11}^{-1} Z_{i1} + \langle \tilde{z}_{t,3}^\pi, \tilde{y}_{t,2}^\pi \rangle \Sigma_{y2,y2} \left( \delta_{yy}^{21} - \delta_{yy}^{32} Z_{11}^{-1} Z_{11} \right) + o_P(T^{-1}), \\
J_{3,3} &= \left[ \langle \tilde{z}_{t,3}^\pi, \tilde{y}_{t,2}^\pi \rangle \Sigma_{y2,y2} \delta_{yy}^{21} - \delta_{yy}^{33} \right] Z_{11}^{-1} \left[ \delta_{yy}^{12} \Sigma_{y2,y2} \left( \tilde{y}_{t,2}^\pi, \tilde{z}_{t,3}^\pi \right) - \delta_{yy}^{13} \right] + o_P(T^{-1})
\end{align*}
\]

for \( i, j = 1, 2 \) where expressions for the remaining blocks of \( J \) follow from symmetry. Hence \( J_{i,j} = O_P(T^{-1}) \) for \( i, j = 1, 2 \). Further \( J_{3,i} = O_P(T^{-1/2}) \) for \( i = 1, 2, 3 \). \( J_{3,3} = O_P(T^{-1}) \) and \( J_{3,3} = O(\log T)^3/T \) respectively.

(III) \( \delta G = O_P(T^{-1/2}) \).

**Proof:** (I) follows from Lemma A.10. Note that compared to the OLS case in the (3,3) entry of \( \tilde{\Phi} \) the matrix \( \langle \tilde{y}_{t,2}^\pi, \tilde{y}_{t,2}^\pi \rangle \) is replaced with \( \hat{\Sigma}_{y2,y2} = \langle \tilde{y}_{t,2}^\pi, \tilde{y}_{t,2}^\pi \rangle + o_P(T^{-1/2}) \) in order to obtain \( \delta_{yy}^{22} = 0 \) rather than \( o_P(T^{-1/2}) \). Only the in probability statements are used.

The proof of (II) then is unchanged except that \( \delta_{yy}^{23} = o_P(T^{-1/2}) \) needs to be taken into account. (III) is then immediate. \( \square \)

Next the proof of Lemma A.7 uses only the results of Lemma A.6 and equation (12) in combination with the following limit results:

\[
\sqrt{T} \left( \delta_{yy}^{21} - \delta_{yy}^{11} \right) \langle \tilde{y}_{t,2}^\pi, \tilde{y}_{t,2}^\pi \rangle^{-1} = \Xi + o(1),
\]

\[
\sqrt{T} \left[ J_{3,1} - \delta_{zz}^{31} \right] = E \tilde{\Xi}_{t,2}^\Pi \langle \tilde{y}_{t,2}^\pi \rangle^\prime \Xi^\prime + o_P(1),
\]

\[
T \langle \tilde{z}_{t,2,1}^\pi, \tilde{z}_{t,2,1}^\pi \rangle^{-1} J_{2,1,1} = \left( T^{-1} \langle \tilde{z}_{t,2,1}^\pi, \tilde{z}_{t,2,1}^\pi \rangle \right)^{-1} \left( \langle \tilde{z}_{t,2,1}^\pi, \tilde{\epsilon}_{t,1,2} \rangle + \tilde{B}_{1,2,1} + \tilde{B}_{2,2,1} \tilde{\Xi}^\prime \right) + o_P(1),
\]

\[
\sqrt{T} \left( \tilde{z}_{t,2,1}^\pi - \tilde{z}_{t,2,1}^\pi \right)^{-1} J_{2,1,3} = \left( \langle \tilde{z}_{t,2,1}^\pi, \tilde{y}_{t,2}^\pi \rangle + \tilde{B}_{1,2,1} \right)^\prime \Sigma_{y2,y2} \tilde{O}_{t,3} \tilde{Z}_{3,3} + o_P(1).
\]

where again \( \Xi := -E \tilde{\epsilon}_{t,1} \tilde{y}_{t,2}^\pi \Sigma_{y2,y2} \tilde{\epsilon}_{t,1,2} \) and \( \tilde{\epsilon}_{t,1,2} = \tilde{\epsilon}_{t,1} + \Xi \tilde{y}_{t,2}^\pi \). Further (\( \tilde{B}^+ \) denoting the transformed quantity \( \tilde{B}^+ \))

\[
\tilde{B}_{1,2,1} = [I, 0] \tilde{B}^+ [-Z_{21} \tilde{Z}_{11}^{-1}, I, 0]^\prime, \quad \tilde{B}_{2,2,1} = [0, I] \tilde{B}^+ [-Z_{21} \tilde{Z}_{11}^{-1}, I, 0]^\prime.
\]
Here the first statement follows from Lemma A.10. The second from the fact that the (1,3) block of $\Sigma_{y,z}$ is of order $o_p(T^{-1/2})$ relating to a stationary component of the regressors. The remaining statements follow straightforwardly from the definition of $J$.

Lemma A.12 Let the assumptions of Theorem 3.3 hold.

(I) Then

$$T_y(\hat{\beta}_{RRR} - b_r)T_z^{-1}D_z^{-1} = \sqrt{T} \left[ \langle \hat{\varepsilon}_t, \hat{z}_t^\pi \rangle + \hat{B}^+ \right] \tilde{D}_2 \tilde{\Gamma}^\dagger + \begin{bmatrix} T I & 0 \\ 0 & \sqrt{T} O \end{bmatrix} \delta G'(I - \tilde{M} \tilde{G}^\dagger)$$

$$+ \begin{bmatrix} 0 & 0 \\ 0 & \sqrt{T} \tilde{Z}_{23} \tilde{D}_2 \tilde{\Gamma}^\dagger \delta G_3^\dagger \tilde{Z}_{32} \tilde{\Gamma}^\dagger \delta G_3^\dagger \end{bmatrix} + o_p(1)$$

where

$$\tilde{Z}_{23} = \langle \hat{y}_{t,2}^\pi, \hat{z}_{t,3}^\pi \rangle \tilde{\Gamma}_{3,2} \tilde{\Gamma}_{3,2}^\dagger = \tilde{O}_2 \tilde{\Gamma}_{3,2} \tilde{O}_2 \tilde{\Gamma}_{3,2} = \tilde{b}_{2,3}$$

denotes the solution to the subproblem of the problem (b) corresponding to the stationary components. $\tilde{\Gamma}_{3,2} := (\tilde{\Gamma}_{3,2}^\dagger \langle \hat{z}_{t,3}^\pi, \hat{z}_{t,3}^\pi \rangle \tilde{\Gamma}_{3,2})^{-1} \tilde{\Gamma}_{3,2}^\dagger$.

(II) Letting $\delta G_{3,1}$ and $\delta G_{3,2}$ denote the first and second block column of $\delta G$ it holds that

$$T \delta G_{3,1}^\dagger (I - \tilde{M} \tilde{G}^\dagger) = \begin{bmatrix} -T \delta H' Z_{21} Z_{11}^{-1} & T \delta H' & T \delta G_{3,1} \tilde{P} \end{bmatrix} + o_p(1), \quad (26)$$

$$\sqrt{T} \delta G_{3,2}^\dagger (I - \tilde{M} \tilde{G}^\dagger) = \sqrt{T} \delta G_{3,2}^\dagger \begin{bmatrix} -Z_{21} Z_{11}^{-1} & I & 0 \end{bmatrix} + o_p(1) \quad (27)$$

where $\delta H = \delta G_{2,1} - \delta G_{2,2} (\tilde{\Gamma}_{3,2}^\dagger \langle \hat{z}_{t,3}^\pi, \hat{z}_{t,3}^\pi \rangle \tilde{\Gamma}_{3,2}) \delta G_{3,1}$ and $\tilde{P} = I - Z_{33} \tilde{\Gamma}_{3,2} \tilde{\Gamma}_{3,2}^\dagger$.

The only change in the proof consists in exchanging the estimation error for the OLS estimator by the estimation error for the FM estimator in (I). The rest of the proof is analogously to the OLS case and hence omitted. Primarily the orders of convergence derived above are used.

It remains to analyze the asymptotic distribution of the various terms. This is done in the analogon to Lemma A.9:

Lemma A.13 With $\hat{\varepsilon}_t = (\hat{\varepsilon}_t^2 (\tilde{y}_{t,2}^\pi (\hat{y}_{t,2}^\pi))^{-1} \hat{O}_2 (\tilde{y}_{t,2}^\pi (\hat{y}_{t,2}^\pi))^{-1}$ we have

$$\langle \hat{\varepsilon}_t, \hat{z}_{t,3}^\pi \rangle d \rightarrow f \left( T_y \Lambda B, W_{z,1}, 0 \right),$$

$$\sqrt{T} \langle \hat{\varepsilon}_t, \hat{z}_{t,3}^\pi \rangle d \rightarrow \mathcal{N}(0, V),$$

$$\sqrt{T} \delta G_{2,2} = Z_{22,1}^{-1} \langle \hat{\varepsilon}_{t,2}, \hat{z}_{2,2}^\pi \rangle + \hat{B}_{2,2,1} (\hat{O}_2) + o_p(1) d \rightarrow M_{2,+}' (\hat{O}_2)'.$$
\[ T \bar{P} \delta G_{3,1} = Z_{33}^{-1} P' \sqrt{T} \langle \tilde{z}_{t,3}, \tilde{e}_{t,1,2} \rangle + Z_{33}^{-1} \sqrt{T} (P' - P') \mathbb{E} \tilde{z}_{t,3} (\hat{\theta}_{t,2})' \Xi' + o_P(1) \rightarrow \tilde{R}', \]

\[ T \delta H = Z_{22,1}^{-1} \left[ \langle \tilde{z}_{t,2,1}, \tilde{e}_{t,1} \rangle + B_{1,2,1} + \left( \langle \tilde{z}_{t,2,1}, \tilde{e}_{t,2} \rangle + B_{2,2,1} \right) (I - \tilde{O}_2 \tilde{O}_2') \right] + o_P(1), \]

\[ \sqrt{T} [\bar{\beta}_{2,3} - \hat{\beta}_{2,3}] P = \tilde{O}_2 \tilde{O}_2' \sqrt{T} \langle \tilde{e}_{t,2}, \tilde{z}_{t,3} \rangle (\mathbb{E} \tilde{z}_{t,3} (\hat{\theta}_{t,3})')^{-1} P + o_P(1), \]

where \( P = (I - \mathbb{E} \tilde{z}_{t,3} (\hat{\theta}_{t,3})' \Gamma_{3,2} \Gamma_{3,2}') \). Here \( M_{2,1} = f([0, I] T_B W_{z,2} - Y_{21} Y_{11}^{-1} W_{z,1}, 0) \) and \( N_+ = f([I, 0] + \Xi (I - O_2 O_2') [0, I] T_B W_{z,2} - Y_{21} Y_{11}^{-1} W_{z,1}, 0). \)

\( T \bar{P} \delta G_{3,1} \) and \( \sqrt{T} [\bar{\beta}_{2,3} - \beta] P \) converge in distribution to Gaussian random variables with mean zero.

The proof follows analogously to the OLS case. The remaining steps of the proof are analogous to the proof for Theorem 3.2 and hence omitted.
B Collection of notation

In this section the notation is presented in order to make reference easier. The general concept is to use lower case letters for processes (where $y$ is reserved for the dependent variable, $z$ denotes regressors and $v, w, u$ is reserved for stationary processes, $\varepsilon, \eta$ denote white noise). Processes built using a number of coordinates of other processes are indicated using sub- or superscripts. Regression residuals are indicated using a superscript $\pi$ (where the regressors are clear from the context) and their corresponding limits with a superscript $\Pi$ (this notation is only used, if limits exist).

Upper case letters are used for matrices. Matrices that transform the basis of processes are indicated using $T$ where the transformed process is indicated as a subscript. Scaling matrices that are introduced in order to ensure the convergence of matrices are denoted using $D$ with subscripts denoting the processes to which they are applied.

Estimates in the original basis are denoted using $\hat{\cdot}$, in the transformed basis (see Theorem 3.1) with $\tilde{\cdot}$ and in the transformed basis with appropriate scaling ensuring convergence with $\bar{\cdot}$ or $\check{\cdot}$ respectively.

B.1 Processes

Below $a_t, b_t$ are used to denote arbitrary processes, where the notation applies to a number of different processes.

\[
y_t = b_r z_t^r + b_u z_t^u + L \varepsilon_t,
\]
\[
z_t = \begin{bmatrix} z_t^r \\ z_t^u \end{bmatrix}, \quad \text{diag}(\Delta, I) H'_p z_t^r = v_t, \quad \text{diag}(\Delta, I) H'_u z_t^u = w_t,
\]
\[
\nu_t = \begin{bmatrix} v_t \\ w_t \end{bmatrix} = c(z) \varepsilon_t, \quad c(0) = 0, \quad \det c(1) \neq 0,
\]
\[
\langle a_t, b_t \rangle = T^{-1} \sum_{t=1}^T a_t b_t^t,
\]
\[
a_t^\pi = a_t - \langle a_t, z_t^u \rangle (z_t^u, z_t^u)^{-1} z_t^u (\rightarrow a_t^{\Pi}(\text{if convergent})) ,
\]
\[
\tilde{y}_t = T_y(y_t - b_u z_t^u) = \tilde{b}_r \tilde{z}_t + \tilde{\varepsilon}_t = \begin{bmatrix} I & 0 & 0 \\ 0 & 0 & \tilde{b}_{2,3} \end{bmatrix} \begin{bmatrix} \tilde{z}_{t,1} \\ \tilde{z}_{t,2} \\ \tilde{z}_{t,3} \end{bmatrix} + \begin{bmatrix} \tilde{\varepsilon}_{t,1} \\ \tilde{\varepsilon}_{t,2} \end{bmatrix},
\]
\[
\tilde{z}_t = T_{z,r} z_t^r = \begin{bmatrix} \tilde{z}_{t,1} \\ \tilde{z}_{t,2} \\ \tilde{z}_{t,3} \end{bmatrix},
\]
\[
\Delta \tilde{z}_{t,1} = \tilde{c}_{z,1}(z) \varepsilon_t, \quad \Delta \tilde{z}_{t,2} = \tilde{c}_{z,2}(z) \varepsilon_t, \quad \tilde{z}_{t,3} = \tilde{c}_{z,3}(z) \varepsilon_t \quad \text{stationary}
\]
\[ \bar{z}_t^u = T_{z,u} \tilde{z}_t^u = \begin{bmatrix} \bar{z}_t^1 \\ \bar{z}_t^2 \end{bmatrix}, \]
\[ \Delta \bar{z}_{t,1}^u = \tilde{c}_{u,1}(z) \varepsilon_t, \quad \bar{z}_{t,2}^u = \tilde{c}_{u,2}(z) \varepsilon_t \quad \text{stationary,} \]
\[ \begin{bmatrix} \tilde{c}_{z,1}(1) \\ \tilde{c}_{z,2}(1) \\ \tilde{c}_{u,1}(1) \end{bmatrix} \quad \text{is of full row rank.} \]

**B.2 Matrices**

\( b_r \in \mathbb{R}^{s \times m_r} \) coefficient matrix corresponding to \( z_t^r \)

\( b_u \in \mathbb{R}^{s \times m_u} \) coefficient matrix corresponding to \( z_t^u \)

\( b = [b_r, b_u] \) coefficient matrix corresponding to \( z_t \).

\( T_y \in \mathbb{R}^{s \times s} \) used to transform \( y_t \) into \( \tilde{y}_t \) separating stationary from nonstationary terms.

\( T_{z,r} \in \mathbb{R}^{m_r \times m_r} \) used to transform \( z_t^r \) into \( \tilde{z}_t \) separating stationary from nonstationary terms.

\( T_{z,u} \in \mathbb{R}^{m_u \times m_u} \) used to transform \( z_t^u \) into \( \tilde{z}_t^u \) separating stationary from nonstationary terms.

\( T_z = \text{diag}(T_{z,r}, T_{z,u}) \).

\( \tilde{b}_r = T_y b_r T_{z,r}^{-1} \).

\( \tilde{b}_u = T_y b_u T_{z,u}^{-1} \).

\( \hat{\beta}_{OLS} \) OLS estimator of \( \beta \).

\( \hat{\beta}_{OLS,r} \) OLS estimator of \( b_r \)

\( \hat{\beta}_{OLS,u} \) OLS estimator of \( b_u \)

\( \tilde{\beta}_{OLS} \) OLS estimator of \( \tilde{b} \).

\( \tilde{\beta}_{OLS,r} \) OLS estimator of \( \tilde{b}_r \)

\( \tilde{\beta}_{OLS,u} \) OLS estimator of \( \tilde{b}_u \)

\( \hat{\beta}_{RRR} \) RRR estimator of \( b \).

\( \hat{\beta}_{RRR,r} \) RRR estimator of \( b_r \)

\( \hat{\beta}_{RRR,u} \) RRR estimator of \( b_u \)
$\hat{\beta}_{RRR}$ RRR estimator of $\tilde{b}$.

$\hat{\beta}_{RRR,r}$ RRR estimator of $\tilde{b}_r$

$\hat{\beta}_{RRR,u}$ RRR estimator of $\tilde{b}_u$

$\hat{\Xi}_+ \in \mathbb{R}^{s \times s}$ weighting matrix.

$$\Xi = -\mathbb{E} \tilde{\varepsilon}_t \tilde{y}_t (\mathbb{E} \tilde{y}_t^\top \tilde{y}_t)^{-1}$$

$M_r = f(W_t, W^\Pi_t)$ where $W$ denotes the Brownian motion corresponding to $(\varepsilon_t)_{t \in \mathbb{N}}$, $W_z = \tilde{c}_{1,2}(1)W, W_u = \tilde{c}_{u,1}(1)W$, $W^\Pi_z = W_z - \int W_z W'_u (\int W_u W'_u)^{-1} W_u$. Further $f(W_1, W_2) = \int dW_1 W_2 (\int W_2 W'_2)^{-1}$.

$M_u = f(W_t, W_u)$.

$N_r = \int W_z W'_u (\int W_u W'_u)^{-1}$.

$M_{r,2} = f([0, 1]^T y_t W_t W^\Pi_{z,2} - Y_{21} Y_{11}^{-1} W^\Pi_{z,1})$.

$Y_{t1} = \int W^\Pi_{z,1} (W^\Pi_{z,1})'$.

$P = I - \mathbb{E} \tilde{z}^\Pi_{t,3} \tilde{z}^\Pi_t \Gamma_{3,2} \Gamma_{3,2}^\top, \Gamma_{3,2}^\top = (\Gamma_{3,2}' \mathbb{E} \tilde{z}^\Pi_{t,3} \tilde{z}^\Pi_t \Gamma_{3,2})^{-1} \Gamma_{3,2}$.

$\bar{P}_{3,3} = \langle \tilde{z}^\Pi_{t,3}, \tilde{z}^\Pi_t \rangle - \langle \tilde{z}^\Pi_{t,3}, \tilde{z}^\Pi_t \rangle \Gamma_{3,2} \Gamma_{3,2}^\top (\tilde{z}^\Pi_{t,3}, \tilde{z}^\Pi_t)$.

$D_y = \text{diag}(T^{-1} I_{c_y}, T^{-1/2})$ proper scaling for $\tilde{y}_t^\Pi$.

$D_{z,r} = \text{diag}(T^{-1} I_{c_r}, T^{-1/2})$ proper scaling for $\tilde{z}_t^\Pi$.

$D_{z,u} = \text{diag}(T^{-1} I_{c_u}, T^{-1/2})$ proper scaling for $\tilde{z}_t^\Pi$.

$D_z = \text{diag}(D_{z,r}, D_{z,u})$

$\tilde{D}_z = D_z T^{1/2} = \text{diag}(T^{-1/2} I, I), \quad \tilde{D}_y = D_y T^{1/2} = \text{diag}(T^{-1/2} I, I)$

$\tilde{G} = \tilde{D}_z^{-1} \tilde{G}$

$Q = \langle \tilde{D}_z \tilde{z}_t^\Pi, \tilde{D}_y \tilde{y}_t^\Pi \rangle \langle \tilde{D}_y \tilde{y}_t^\Pi, \tilde{D}_y \tilde{y}_t^\Pi \rangle^{-1} \langle \tilde{D}_y \tilde{y}_t^\Pi, \tilde{D}_z \tilde{z}_t^\Pi \rangle$

$\tilde{M} = \langle \tilde{D}_z \tilde{z}_t^\Pi, \tilde{D}_z \tilde{z}_t^\Pi \rangle$

$\tilde{\Phi} = \begin{bmatrix}
T^{-1} \langle \tilde{z}^\Pi_{t,1}, \tilde{z}^\Pi_{t,1} \rangle & T^{-1} \langle \tilde{z}^\Pi_{t,1}, \tilde{z}^\Pi_{t,2} \rangle & 0 \\
T^{-1} \langle \tilde{z}^\Pi_{t,2}, \tilde{z}^\Pi_{t,1} \rangle & T^{-1} \langle \tilde{z}^\Pi_{t,2}, \tilde{z}^\Pi_{t,2} \rangle & 0 \\
0 & 0 & \langle \tilde{z}^\Pi_{t,3}, \tilde{y}_{t,2} \rangle \langle \tilde{y}_{t,2}, \tilde{y}_{t,2} \rangle^{-1} \langle \tilde{y}_{t,2}, \tilde{z}^\Pi_{t,3} \rangle
\end{bmatrix}$
| Original Formula                                      | Transformed Formula Relations | Stationary subproblem Formula Relations |
