Dark Matter - A Brief Review

What is known:

- A source of hidden mass/matter.
- Abundance: 84% of the matter density, 26% of the energy density.
- Non-relativistic.
- Very long lived, interacts with Standard Model very weakly, self-interactions are rare.
- Weakly Interacting Massive Particle (WIMP) is a common paradigm.

This says very little about its particle nature. Still do not know:

- Mass.
- Interactions with Standard Model matter.
  - So far have only observed its presence through gravitational interactions with SM particles.
  - May only interact gravitationally with the SM.
$\mathcal{L} = -\frac{1}{4} A'_{\mu \nu}^2 - \frac{1}{2} m_{A'}^2 A'_{\mu}^2 + \epsilon A'_\nu \partial_\mu F_{\mu \nu} + |(\partial_\mu - g_D A'_{\mu}) \chi|^2 - m_\chi^2 |\chi|^2 + \mathcal{L}_{h'}$

- Sub-GeV scalar DM candidate $\chi$ charged under $U(1)'$. The $A'$ (I will sometimes call it a $V$) is the gauge boson of $U(1)'$ symmetry.
- Four model parameters:
  - $m_{A'}$, $m_\chi$, $\epsilon$ and $\alpha_D$ (often labelled $\alpha'$)
- $A'$ can be produced through kinetic mixing with $\gamma$ at $O(\epsilon^2)$.
  - For $2m_\chi < m_{A'}$, $\text{Br}(A' \to \chi \bar{\chi}) \sim 1$ and $A'$ decay is prompt. For $2m_\chi > m_{A'}$, $\text{Br}(V \to \text{SM}) \sim 1$.
- We set $U(1)'$ coupling strength $\alpha_D = 0.5$.
  - Largest possible value without significant running in coupling [Davoudiasl’15, 1502.07383].
- Thermal relic.
  - $\sigma(\chi \bar{\chi} \to l\bar{l}) \propto \epsilon^2 \alpha_D \left(\frac{m_\chi}{m_{A'}}\right)^4$
Searching for Dark Matter

Collider

Build detectors deep underground and search for scatterings between cosmic dark matter and nuclei or electrons.

Direct

Indirect

Use earth and space based telescopes to search for signals (photons or cosmic rays) from cosmic dark matter decays and annihilations.

Produce dark matter in high energy collisions, search for missing energy.
Searching for Dark Matter

Collider

SM \rightarrow DM \rightarrow SM

Produce dark matter in high energy collisions, search for missing energy.

Direct

DM \rightarrow DM \rightarrow SM

Build detectors deep underground and search for scatterings between cosmic dark matter and nuclei or electrons.
Production of Dark Matter at a CEνNS experiments

Combine **Collider** (production) and **Direct** (detection) search strategies to find light dark matter at FTNEs.

- Production of dark matter could occur through many channels. Relevant channels at low energies include:
  - Radiative decays of $\pi^0 \rightarrow \gamma A'\ast$.
  - Radiative $\pi^-$ capture: $p + N \rightarrow \pi^-, \pi^- + p \rightarrow n + A'\ast$.
    - BR $\sim$40% on protons, but drops to a few % for larger nuclei.

See [Pospelov, Tsai, 1706.00424] and [Chiang '89].
Production of Dark Matter at CEνNS experiments

Combine **Collider** (production) and **Direct** (detection) search strategies to find light dark matter at FTNEs.

- **Timing** provides an important handle on the hidden sector signal:
  - Dark matter production is prompt, so it can benefit from any timing structure in the beam.
  - Dark matter arrives at the detector before delayed neutrino signals or other backgrounds.
  - Significant advantage to short bunches.

\[
\begin{align*}
\pi^- + p &\rightarrow p + A' \rightarrow p + \chi\bar{\chi} \\
\pi^0 &\rightarrow \gamma A' \rightarrow \gamma\chi\bar{\chi}
\end{align*}
\]
We can search for hidden sector dark matter through its interactions with nucleons or electrons.

Dark matter scattering signature resembles NCE (neutral current elastic) $\nu$ scattering.

A simple counting experiment is possible, but may fail to generate a significant signal above the neutrino signal and other backgrounds without very large POT.

$$\sigma_{\chi N,e \rightarrow \chi N,e} \propto \epsilon^2 \alpha' \alpha$$
Detecting Low Mass Dark Matter - Coherent Scattering

- Example plots made with 800 MeV proton beam, scattering on Argon.
- $\sigma_{\chi Z \rightarrow \chi Z} \propto Z^2 F_{\text{Helm}}(q^2)$.
- High-recoil tail of scattering distribution grows with the mass of the dark matter.
- Decline in overall event rate due in large part to decline in scattering cross section with increasing mass rather than production rate.
- Switch to incoherent scattering for $q^2 > (50 \text{ MeV})^2$. 
Experimental Constraints

Cosmological:

- **Big Bang Nucleosynthesis** - So long as $m_{DM} > 1 - 2$ MeV, freeze-out occurs before BBN [Serpico & Raffelt '04, Jedamzik & Pospelov '09].

- **Cosmic Microwave Background** - Annihilation through p-wave, has little effect [Padmanabhan & Finkbeiner et al '05; Slatyer et al '08].

Particle Physics:

- $A' \rightarrow l^+l^-$ - Weak so long as $\text{Br}(A' \rightarrow 2\chi) \sim 1$, holds for most of parameter space of interest. [Bjorken et al. '09; Batell et al '09; Reece & Wang '09; MAMI '11, APEX '11, BaBar'12, ...]

Direct Dark Matter Detection:

- DAMIC, LUX, (Super)CDMS(lite), CRESST-II, CRESST-III, XENON10/100/1T...

- DM-electron scattering can reach lower dark matter masses [Essig'17, arXiv:1703.00910]
Experimental Constraints

COHERENT 29kg LAr Engineering Run

- Detector located 28.3 meters from target at large angle.
- Predicted $112 \pm 30$ background events, observed $126 \pm 15$
- Placed a $1\sigma$ upper limit of 7.4 coherent neutrino-nucleus scattering events.
- Plotted 7.4 events from light dark matter scenario.

[COHERENT arXiv:1909.05913]
Looking only at Hadronic Couplings...

Baryophilic, Pseudo–Dirac, $m_\chi = 10$ MeV

$R = m_{A'/m_\chi}$

$y = e^2 \alpha_D (m_\chi/m_{A'})^4$

[Caveat: Models without lepton-couplings tend to have many other strong constraints (see arXiv:1705.06726), may not be a good thermal relic, plot generated for easy rescaling.]

[A. Berlin, PDN, P. Schuster, A. Ritz, N. Toro arXiv:1911.XXXXX]
COHERENT 1T

- Scaling up to a possible 1T detector.
- Would require reduction in background, but does have significant potential reach.
- COHERENT may be able to take significantly more than $10^{23}$ POT, which would dramatically improve its potential reach.
Coherent CAPTAIN-Mills (CCM)

- 7 tons of Liquid Argon with 3 tons of veto.
- Located at Los Alamos National Laboratory.
  - 800 MeV proton beam.
- As with COHERENT, located $> 90^\circ$ off-axis.
- See Edward Dunton’s talk on Sunday for more details.
Dark Matter at CCM

- Simulation performed for 10T LAr located 20 meters from stopped pion source.
- Shielding is still being assembled, backgrounds not yet well known.
- Timing is an excellent tool for reducing background, but may be challenging.
Summary

- Thermal relic particles with a sub-GeV mass and interactions mediated by a light $U(1)'$ vector boson provides a viable dark matter candidate.
- This candidate escapes many of the best limits imposed by standard direct, indirect and collider searches.
- Counting experiment with LSND and MiniBooNE’s DM-Electron scattering analysis provide strong constraints, though now surpassed by NA64.
- Proposed CEνNS experiments like COHERENT and CCM are well placed to search for $\mathcal{O}(10\text{ MeV})$ dark matter candidates.
- Simple variations on the benchmark scenario, such as a leptophobic or inelastic dark matter, possess different sets of constraints, and can also be targeted by proton beam experiments.
