LOCAL COMPARISONS OF HOMOLOGICAL AND HOMOTOPICAL MIXED HODGE POLYNOMIALS

SHOJI YOKURA

Abstract. For a simply connected complex algebraic variety $X$, by the mixed Hodge structures $(W_\bullet, F^\bullet)$ and $(\tilde{W}_\bullet, \tilde{F}^\bullet)$ of the homology group $H_\ast(X;\mathbb{Q})$ and the homotopy groups $\pi_\ast(X) \otimes \mathbb{Q}$ respectively, we have the following mixed Hodge polynomials

$$MH_X(t, u, v) := \sum_{k,p,q} \dim \left( \text{Gr}^p_F \text{Gr}^W_{p+q} H_k(X; \mathbb{C}) \right) t^k u^{-p} v^{-q},$$

$$MH_X^\pi(t, u, v) := \sum_{k,p,q} \dim \left( \text{Gr}^p_F \text{Gr}^\tilde{W}_{p+q}(\pi_k(X) \otimes \mathbb{C}) \right) t^k u^{-p} v^{-q},$$

which are respectively called the homological mixed Hodge polynomial and the homotopical mixed Hodge polynomial. In this paper we discuss some inequalities concerning these two mixed Hodge polynomials.

1. Introduction

For a complex algebraic variety $X$ there exists a mixed Hodge structure $(W_\bullet, F^\bullet)$ on the homology group $H_\ast(X;\mathbb{Q})$ ([2], [3]). In [10] J. W. Morgan first put mixed Hodge structures on the rational homotopy groups in the smooth case. Then, Morgan’s results were extended to singular varieties by R. M. Hain ([7], cf. [5]) and V. Navarro-Aznar ([11]) independently (e.g., see [12], p.234, Historical Remarks).

Then as defined in the abstract we can define the following polynomials of three variables $t, u, v$ (see Remark 1.1 below):

$$MH_X(t, u, v) := \sum_{k,p,q} \dim \left( \text{Gr}^p_F \text{Gr}^W_{p+q} H_k(X; \mathbb{C}) \right) t^k u^{-p} v^{-q},$$

$$MH_X^\pi(t, u, v) := \sum_{k,p,q} \dim \left( \text{Gr}^p_F \text{Gr}^\tilde{W}_{p+q}(\pi_k(X) \otimes \mathbb{C}) \right) t^k u^{-p} v^{-q}.$$
Remark 1.2. In order to get the mixed Hodge structure on the homotopy groups, in fact it suffices that the algebraic variety is nilpotent in the sense that $\pi_1$ is nilpotent and acting nilpotently on higher homotopy groups (e.g., see [12 Remark 8.12]). Simply connected is then a particular case.

The first polynomial is well-known, usually called the mixed Hodge polynomial and has been studied very well. The second one is a homotopical analogue, defined by the mixed Hodge structure on the homotopy groups $\pi_*(X)$. So, we call these two polynomials respectively the homological mixed Hodge polynomial and the homotopical mixed Hodge polynomial. Here we observe the following for the special values $(u, v) = (1, 1)$:

$$P_X(t) = MH_X(t, 1, 1) = \sum_{k \geq 0} \dim H_k(X; \mathbb{C}) t^k = 1 + \sum_{k \geq 1} \dim H_k(X; \mathbb{C}) t^k,$$

$$P^\pi_X(t) = MH^\pi_X(t, 1, 1) = \sum_{k \geq 2} \dim(\pi_k(X) \otimes \mathbb{C}) t^k = \sum_{k \geq 2} \dim(\pi_k(X) \otimes \mathbb{Q}) t^k.$$

The first polynomial is the usual Poincaré polynomial and the second one is its homotopical analogue, called the homotopical Poincaré polynomial.

In this note we discuss some inequalities concerning these two mixed Hodge polynomials $MH_X(t, u, v)$ and $MH^\pi_X(t, u, v)$. More details will appear elsewhere.

2. Homological mixed Hodge polynomial and homotopical mixed Hodge polynomial

The most important and fundamental topological invariant in geometry and topology is the Euler–Poincaré characteristic $\chi(X)$, which is defined to be the alternating sum of the Betti numbers $\beta_i(X) := \dim_{\mathbb{Q}} H_i(X; \mathbb{Q}) = \dim_{\mathbb{C}} H_i(X; \mathbb{C})$:

$$\chi(X) := \sum_{i \geq 0} (-1)^i \beta_i(X),$$

provided that each $\beta_i(X)$ and $\chi(X)$ are both finite. Similarly, for a topological space whose fundamental group is an Abelian group one can define the homotopical Betti number $\beta^\pi_i(X) := \dim(\pi_i(X) \otimes \mathbb{Q})$ where $i \geq 1$ and the homotopical Euler–Poincaré characteristic:

$$\chi^\pi(X) := \sum_{i \geq 1} (-1)^i \beta^\pi_i(X),$$

provided that each $\beta^\pi_i(X)$ and $\chi^\pi(X)$ are both finite. The Euler–Poincaré characteristic is the special value of the Poincaré polynomial $P_X(t)$ at $t = -1$ and the homotopical Euler–Poincaré characteristic is the special value of the homotopical Poincaré polynomial $P^\pi_X(t)$ at $t = -1$:

$$P_X(t) := \sum_{i \geq 0} t^i \beta_i(X), \quad \chi(X) = P_X(-1),$$

$$P^\pi_X(t) := \sum_{i \geq 1} t^i \beta^\pi_i(X), \quad \chi^\pi(X) = P^\pi_X(-1).$$

The Poincaré polynomial $P_X(t)$ is multiplicative in the following sense:

$$P_{X \times Y}(t) = P_X(t) \times P_Y(t),$$
which follows from the Künneth Formula:
\[ H_n(X \times Y; \mathbb{Q}) = \sum_{i+j=n} H_i(X; \mathbb{Q}) \otimes H_j(Y; \mathbb{Q}). \]

The homotopical Poincaré polynomial \( P^\pi_X(t) \) is additive in the following sense:
\[ P^\pi_{X \times Y}(t) = P^\pi_X(t) + P^\pi_Y(t), \]
which follows from
\[ \pi_*(X \times Y) = \pi_*(X) \times \pi_*(Y) = \pi_*(X) \oplus \pi_*(Y) \]
and \((A \oplus B) \otimes \mathbb{Q} = (A \otimes \mathbb{Q}) \oplus (B \otimes \mathbb{Q})\).

Here we note that
\[ P_X(t) = MH_X(t, 1, 1) \quad P^\pi_X(t) = MH^\pi_X(t, 1, 1). \]

In fact the homological mixed Hodge polynomial is also multiplicative just like the Poincaré polynomial \( P_X(t) \)
\[ MH_{X \times Y}(t, u, v) = MH_X(t, u, v) \times MH_Y(t, u, v) \]
which follows from the fact that the mixed Hodge structure is compatible with the tensor product (e.g., see [12 §3.1, Examples 3.2].) As to the homotopical mixed Hodge polynomial, it is additive just like the homotopical Poincaré polynomial \( P^\pi_X(t) \)
\[ MH^\pi_{X \times Y}(t, u, v) = MH^\pi_X(t, u, v) + MH^\pi_Y(t, u, v) \]
since \( \pi_*(X \times Y) = \pi_*(X) \oplus \pi_*(Y) \) and the category of mixed Hodge structures is abelian and the direct sum of a mixed Hodge structure is also a mixed Hodge structure.

3. Local comparisons of these two mixed Hodge polynomials

By the above definition, we have \( 0 = P_X^\pi(0) = MH^\pi_X(0, 1, 1) < MH_X(0, 1, 1) = P_X(0) = 1. \) Hence we get the following strict inequality:\(^1\)

**Corollary 3.1.**
\[ MH^\pi_X(t, u, v) < MH_X(t, u, v) \]
for \( |t| \ll 1, |u - 1| \ll 1, |v - 1| \ll 1. \)

When \( t = -1 \), \( MH_X(-1, 1, 1) = P_X(-1) = \chi(X) \) is the Euler–Poincaré characteristic and \( MH^\pi_X(-1, 1, 1) = P^\pi_X(-1) = \chi^\pi(X) \) is the homotopical Euler–Poincaré characteristic. In this case we do have the following theorem due to Félix–Halperin–Thomas [31 Proposition 32.16]:

**Theorem 3.2.** We have \( \chi^\pi(X) < \chi(X), \) namely \( MH^\pi_X(-1, 1, 1) < MH_X(-1, 1, 1). \)

Hence we get the following strict inequality:

**Corollary 3.3.**
\[ MH^\pi_X(t, u, v) < MH_X(t, u, v) \]
for \( |t + 1| \ll 1, |u - 1| \ll 1, |v - 1| \ll 1. \)

---

\(^1\)We note that given two real valued polynomial (therefore, continuous) functions \( f(x, y, z) \) and \( g(x, y, z) \), a strict inequality \( f(a, b, c) < g(a, b, c) \) at a special value \( (a, b, c) \) implies a local strict inequality \( f(x, y, z) < g(x, y, z) \) for \( |x - a| \ll 1, |y - b| \ll 1, |z - c| \ll 1 \).
As to the case when \((t, u, v) = (1, 1, 1)\), we have
\[
MH_X(1, 1, 1) = P_X(1) = \sum_{k \geq 0} \dim H_k(X; \mathbb{C}) = 1 + \sum_{k \geq 1} \dim H_k(X; \mathbb{C}),
\]
\[
MH^\pi_X(1, 1, 1) = P^\pi_X(1) = \sum_{k \geq 2} \dim(\pi_k(X) \otimes \mathbb{C}).
\]

For these integers we do have the following Hilali conjecture \[7\], which has been solved affirmatively for many spaces such as smooth complex projective varieties and symplectic manifolds (e.g. see \[1\] [8] [9]), but still open:

**Conjecture 3.4** (Hilali conjecture).

\[
P^\pi_X(1) \leq P_X(1),
\]
i.e., \(MH^\pi_X(1, 1, 1) \leq MH_X(1, 1, 1)\).

**Remark 3.5.** The inequality \(\leq\) in the Hilali conjecture cannot be replaced by the strict inequality \(<\). It follows from the minimal model of the de Rham algebra of \(\mathbb{P}^n\) that we have (see \[12\] Example 9.9)
\[
\pi_k(\mathbb{P}^n) \otimes \mathbb{Q} = \begin{cases}
0 & k \neq 2, 2n + 1 \\
\mathbb{Q} & k = 2, 2n + 1.
\end{cases}
\]

In particular, in the case when \(n = 1\), we have
\[
MH^\pi_{\mathbb{P}^1}(t, u, v) = t^2uv + t^3u^2v^2, \quad MH_{\mathbb{P}^1}(t, u, v) = 1 + t^2uv.
\]
So we have that \(MH^\pi_{\mathbb{P}^1}(1, 1, 1) = MH_X(1, 1, 1) = 2\), i.e. \(P^\pi_X(1) = P_X(1) = 2\). We also remark that in the case of (non-strict) inequality \(MH^\pi_X(1, 1, 1) \leq MH_X(1, 1, 1)\), unlike Corollary 3.1 and Corollary 3.3 we cannot expect the following local inequality
\[
MH^\pi_X(t, u, v) \leq MH_X(t, u, v)
\]
for \(|t - 1| \ll 1, |u - 1| \ll 1, |v - 1| \ll 1\). Indeed, clearly the following does not hold:
\[
MH^\pi_{\mathbb{P}^1}(t, 1, 1) = t^2 + t^3 \leq 1 + t^2 = MH_{\mathbb{P}^1}(t, 1, 1)
\]
for \(|t - 1| \ll 1\).

However, using the multiplicativity of the Poincaré polynomial \(P_X(t)\) and the additivity of the homotopical Poincaré polynomial \(P^\pi_X(t)\), we can get the following theorem, which kind of says that the Hilali conjecture holds “modulo product” \[13\]:

**Theorem 3.6.** There exists a positive integer \(n_0\) such that for \(\forall n \geq n_0\) the following strict inequality holds:
\[
P^\pi_X(n)(1) < P_X(n)(1).
\]

Hence, since \(P^\pi_X(n)(1) < P_X(n)(1)\) means \(MH^\pi_X(n, 1, 1, 1) < MH_X(n, 1, 1, 1)\), we have that
\[
MH^\pi_X(n, 1, 1, 1) < MH_X(n, 1, 1, 1) \quad \text{for } \forall n \geq n_0
\]
In fact we can get the following strict inequality, which, should be noted, does not follow straightforwardly from the above strict inequality \[3.7\] and requires a bit of work:

**Corollary 3.8.** There exists a positive integer \(n_0\) such that for \(\forall n \geq n_0\)
\[
MH^\pi_X(n, t, u, v) < MH_X(n, t, u, v)
\]
for \(|t - 1| \ll 1, |u - 1| \ll 1, |v - 1| \ll 1\).
In fact, in a similar way, using the multiplicativity of the mixed Hodge polynomial, i.e., (2.1) and the additivity of the homotopical mixed Hodge polynomial, i.e., (2.2), we can show the following theorem. Let $\mathbb{R}_{>0}$ be the set of positive real numbers.

**Theorem 3.9.** Let $(s, a, b) \in (\mathbb{R}_{>0})^3$. Then there exists a positive integer $n_{(s, a, b)}$ such that for $\forall n \geq n_{(s, a, b)}$ the following strict inequality holds

$$MH^\pi_X n(t, u, v) < MH^n_X (t, u, v).$$

for $|t - s| \ll 1, |u - a| \ll 1, |v - b| \ll 1$.

The following theorem follows from the above theorem and the compactness of the following compact cube $\mathcal{C}_{\varepsilon, r}$.

**Theorem 3.10.** Let $\varepsilon, r$ be positive real numbers such that $0 < \varepsilon \ll 1$ and $\varepsilon < r$ and $\mathcal{C}_{\varepsilon, r} := [\varepsilon, r] \times [\varepsilon, r] \times [\varepsilon, r] \subset (\mathbb{R}_{>0})^3$ be a cube. Then there exists a positive integer $n_{\varepsilon, r}$ such that for $\forall n \geq n_{\varepsilon, r}$ the following strict inequality holds

$$MH^\pi_X n(t, u, v) < MH^n_X (t, u, v)$$

for $\forall (t, u, v) \in \mathcal{C}_{\varepsilon, r}$.

We would like to pose the following conjecture:

**Conjecture 3.11.** Let $\varepsilon$ be a positive real number such that $0 < \varepsilon \ll 1$. There exist a positive integer $n_0$ such that for $\forall n \geq n_0$ the following strict inequality holds

$$MH^\pi_X n(t, u, v) < MH^n_X (t, u, v)$$

for $\forall (t, u, v) \in [\varepsilon, \infty)^3 \subset (\mathbb{R}_{>0})^3$.

In the case when $u = v = 1$, i.e., in the case of $P^\pi_X(t)$ and $P_X(t)$, we do have the following “half-global” version of Theorem 3.6.

**Theorem 3.12.** Let $\varepsilon$ be a positive real number such that $0 < \varepsilon \ll 1$. There exists a positive integer $n_0$ such that for $\forall n \geq n_0$ the following strict inequality holds:

$$P^\pi_X n(t) < P^n_X (t) \quad (\forall t \in [\varepsilon, \infty)).$$

**Acknowledgements:** The author would like to thank the anonymous referee for his/her very useful comments and suggestions. The author also would like to thank Anatoly Libgober for his interest in this work and various comments and suggestions on an earlier version of the paper. Their comments and suggestions improved the paper. In fact, a joint paper with A. Libgober is in preparation and will contain detailed proofs of results of the present paper as well as calculations and further information about mixed Hodge polynomials of elliptic spaces. This work is supported by JSPS KAKENHI Grant Number JP19K03468.
