Phenotypic Determination of Biofilm Formation and Acquired Resistance Profile of Clinically-Derived Bacterial Isolates

Muhammad M. Ibrahim, Abubakar Shettima, Ibrahim Y. Ngoshe, Musa Ibn Abbas, Hauwa S. Bello, Askira M. Umoru, and Isyaka M. Tom

ABSTRACT

Infections caused by biofilm forming bacteria is of major public health concern because of its association with multi-resistance to antimicrobial drugs and host defenses, leading to chronic and recurrent infections. Here, using Congo red agar method, Kirby-bauer disk diffusion technique and the consensus criteria of the European Centre for Disease Control (ECDC) and Centre for Disease Control (CDC), we determined the acquired resistance profile of biofilm producing phenotypes of clinically derived bacteria, classified as Multidrug resistant (MDR), extensively drug resistant (XDR) and Pandrug resistant (PDR). Fifty (50) de-identified bacterial isolates, comprising of five different species (Staphylococcus aureus, Escherichia coli, Proteus spp, Klebsiella pneumoniae and Pseudomonas aeruginosa) were sampled for this study. 64.0% of these isolates were observed to produce biofilms. Isolates recovered from urine samples (50.0%) were the most significant biofilm producers, chief among which was Staphylococcus aureus (15.6%) ($X^2=0.52; p<.05; P=0.9714$). 78.0% of the biofilm producing phenotypes were at least multidrug resistant (31.4% MDR; 31.4% XDR; 15.7% PDR) ($f=0.40678; df=3; p<.05; P=0.7502$). Extreme forms of acquired resistance (XDR and PDR) were more common among biofilm producing strains than the non-biofilm producing strains and was statistically significant ($f=5.54; p=0.026336; df=14; p<.05$). All Staphylococcus aureus and Pseudomonas aeruginosa isolates were at least multidrug resistant, with the biofilm producing strains of the latter being completely resistant to Gentamicin and Ciprofloxacin. As such, it can be deduced that resistance to multiple antimicrobial drugs is more pronounced among biofilm producing phenotypes of clinically derived bacterial isolates.

Keywords: Antimicrobial resistance, Biofilm, Clinical Bacteria, Multidrug resistance.

I. INTRODUCTION

Microbial biofilm is an accretion of bacterial cells enclosed in a matrix of extracellular polymeric substances (EPS) produced by bacterial cells and are attached to biotic or abiotic surfaces. A phenomenon pervasive among a diverse spectrum of bacteria, biofilm formation can be thought of as a survival strategy devised against hostile tendencies and an effective means of dispersal/settlement in a particular niche. It puts into question the notion that pathogens are evenly distributed (planktonic mode of growth) during an infectious disease episode and therefore, evenly susceptible to the antagonistic effects of the host immune response and antibiotics. The opposite has been observed to be the case as bacterial pathogens growing in the form of biofilms are restricted to a surface or exist as an infectious embolus with a highly reduced susceptibility to antibiotics, and the effects of the host immune response [1].

A plethora of infectious diseases (80% of infectious diseases in human) have been linked to biofilm aetiology, with device-related infections being the earliest [2]. Devices such as intravenous catheters, prosthetic heart valves, and endotracheal tubes come with an inherent risk of surface associated infections and the adhesion of bacterial cells to the surface of these devices is aided, to certain extent, by host inflammatory molecules [1]. Bacteria frequently associated with device-related infections include Staphylococcus epidermidis, Staphylococcus aureus, Pseudomonas aeruginosa [1], Enterococcus faecalis, Streptococcus viridans, Klebsiella pneumoniae and Proteus mirabilis [3]. Pseudomonas aeruginosa has been observed to grow within the lungs of Cystic Fibrosis patients [4], [5] where they form clusters of cells enclosed in a dense matrix [6], [7].

Biofilm producing bacteria have been shown to be resistant to multiple antimicrobial drugs [8]. Such extensive resistance has been attributed to factors such as the protective covering afforded by the EPS matrix [9], reduced growth rate due to nutrient limitation within the biofilm matrix [10], embolus size [11], presence of MDR efflux pumps [12], persister cells [13], acquired resistance [14] or the combination of two or more of these factors. The aim here is to investigate the pervasiveness of acquired drug resistance among biofilm...

producing clinical bacterial isolates. This experiment is also geared towards uncovering the difference or otherwise, in resistance rate between biofilm producing and biofilm non-producing clinical bacterial isolates.

II. MATERIALS AND METHODS

A. Study Area

This is a cross-sectional qualitative study that was conducted at the laboratory of the Department of Microbiology, University of Maiduguri, Northeastern Nigeria.

B. Collection and Characterization of Bacterial Isolates

Fifty (50) de-identified clinical bacterial isolates comprising of *Staphylococcus aureus* (10), *Klebsiella pneumoniae* (10), *Proteus* spp (10), *Escherichia coli* (10), and *Pseudomonas aeruginosa* (10) (isolated from Urine, Swab and Sputum) were randomly collected onto nutrient agar slants in Cryovials, from the laboratory of the Department of Medical Microbiology, University of Maiduguri Teaching Hospital and transferred to the laboratory of the Department of Microbiology, University of Maiduguri, where they were sub-cultured and confirmed using standard microbiological procedure [15].

C. Biofilm Formation Test

Detection of biofilm was done according to the method described by [16]. It is a qualitative method for the detection of biofilm production using Congo Red Agar (CRA). CRA is prepared by adding Congo red stain to an autoclaved brain heart infusion agar with sucrose at 55°C. It is poured into culture plates and allowed to cool. It is then inoculated with the test organism and incubated at 37°C for 18-24 hours aerobically. The plates were examined for the production of black colonies which is indicative of biofilm formation.

D. Antibiotic Susceptibility Test

Antibiotic susceptibility test was done using the Kirby Bauer disc diffusion method according to the recommendations of the Clinical Laboratory Standard Institute [17]. Each disc is impregnated with a particular antibiotic of defined concentration. Isolates were streaked onto Mueller Hinton agar plates and the antibiotic-infiltrated discs were aseptically placed on it. It is then incubated at 37°C for 18-24 hours. The diameter of the zone of inhibition were measured to the nearest millimeter. Based on the zone sizes, isolates were designated as either sensitive or resistant in accordance with the interpretation chart as provided by the Clinical Laboratory Standard Institute [17]. The bacterial isolates were tested against the following commonly prescribed antimicrobial drugs: Sulphamethoxazole-Trimethoprim (SXT:30µg), Chloramphenicol (CHL:30µg), Sparfloxacin (SPX:10µg), Ciprofloxacin (CIP:30µg), Amoxicillin (AMX:30µg), Amoxiclav (AMC:30µg), Gentamicin (GEN:10µg), Peflacin (PEF:30µg), Ofloxacin (OFLX:10µg), Streptomycin (STR:30µg), Cefuroxime (CXM:20µg), Ceftriaxone (CRO:25µg), and Erythromycin (E:10µg).

E. Determination of Acquired Resistance Profile of Bacterial Isolates

This was determined according to the criteria jointly recommended by the European Centre for Disease Control (ECDC) and Centre for Disease Control (CDC) and they are as follows:

i. Multi-Drug resistance (MDR): Non-susceptibility to at least one antimicrobial agent in three or more antimicrobial categories.

ii. Extensively Drug-resistance (XDR): Non-susceptibility to at least one antimicrobial agent in all but two or fewer antimicrobial categories (bacterial isolates remain susceptible to only one or two categories).

iii. Pandrug-resistance (PDR): Non-susceptibility to all antimicrobial agents in all antimicrobial categories [18].

F. Data Analysis

Data were collected and grouped into frequencies and percentages, and presented in the form of tables and figures. Chi-square test of association and One-way ANOVA were used to determine the relationship between variables at 95% (p<0.05) level of significance.

III. RESULTS

Out of 50 clinical bacterial isolates examined, 64% (32/50) tested positive to biofilm formation test. 40 (80.0%) were found to be resistant to at least three (3) or more antimicrobial drugs tested. Of this, 22 (44.0%) were MDR, 11 (22.0%) were XDR while 7 (14.0%) were PDR. Difference in acquired resistance among isolates was statistically significant (X² = 12.3409; P= 0.00209; p<.05) (Fig. 1).

*Escherichia coli* and *Staphylococcus aureus* recorded the highest biofilm formation rate (14.0% respectively). Association between sample type and bacteria isolated in relation to biofilm formation revealed that *Staphylococcus aureus* was the most significant biofilm producer identified from urine samples (10.0%); *Klebsiella pneumoniae*, *Proteus* spp and *Staphylococcus aureus* were the most significant biofilm producer identified from swab samples (4.0% respectively), whereas *Escherichia coli* was the most
significant biofilm producer identified from sputum samples (8.0%) (Table I).

In total, isolates identified from Urine samples yielded the highest percentage of biofilm-producing strains (32.0%) while those identified from Swab samples recorded the least (14.0%) (Table II).

### TABLE I: BIOFILM FORMATION IN RELATION TO DIFFERENCE IN SAMPLE OF ORIGIN AND BACTERIAL SPECIES ISOLATED

| Bacterial spp        | Sample of Origin | Biofilm Formation Test | Total (%) | X²/p-value |
|----------------------|------------------|------------------------|-----------|------------|
|                      |                  | Positive (%)           | Negative (%) |            |
|                      |                  | 5 (10.0)               | 1 (2.0)    | 6 (12.0)   |
| Staphylococcus aureus| Urine            | 2 (4.0)                | 2 (4.0)    | 4 (8.0)    |
|                      | Swab             | 0 (0.0)                | 0 (0.0)    | 0 (0.0)    |
|                      | Sputum           | 1 (2.0)                | 1 (2.0)    | 2 (4.0)    |
|                      |                  |                        |            |            |
| Klebsiella pneumoniae| Swab             | 2 (4.0)                | 2 (4.0)    | 4 (8.0)    |
|                      | Sputum           | 3 (6.0)                | 1 (2.0)    | 4 (8.0)    |
|                      | Urine            | 3 (6.0)                | 2 (4.0)    | 5 (10.0)   |
| Escherichia coli     | Swab             | 0 (0.0)                | 0 (0.0)    | 0 (0.0)    |
|                      | Sputum           | 4 (8.0)                | 1 (2.0)    | 5 (10.0)   |
|                      | Urine            | 3 (6.0)                | 1 (2.0)    | 4 (8.0)    |
| Pseudomonas aeruginosa| Swab            | 1 (2.0)                | 3 (6.0)    | 4 (8.0)    |
|                      | Sputum           | 2 (4.0)                | 0 (0.0)    | 2 (4.0)    |
|                      | Urine            | 4 (8.0)                | 3 (6.0)    | 7 (14.0)   |

|                      | Sputum           | 0 (0.0)                | 0 (0.0)    | 0 (0.0)    |
| Total (%)            |                  | 32 (64.0)              | 18 (36.0)  | 50 (100)   |

X²=0.5208; p<.05

### TABLE II: BIOFILM FORMATION BASED ON SAMPLE TYPE FROM WHICH ISOLATES WERE IDENTIFIED

| Biofilm Formation Test | Sample | Urine (%) | Swab (%) | Sputum (%) | Total (%) |
|-----------------------|--------|-----------|----------|------------|-----------|
| Positive              |        | 16 (32.0) | 7 (14.0) | 9 (18.0)   | 32 (64.0) |
| Negative              |        | 8 (16.0)  | 8 (16.0) | 2 (4.0)    | 18 (36.0) |
| Total (%)             |        | 24 (48.0) | 15 (30.0)| 11 (22.0)  | 50 (100)  |

Table III shows the comparative acquired resistance profile of biofilm-producing and non-biofilm producing isolates. 80.0% of the isolates were at least multidrug resistant. It was observed that acquired resistance was more pronounced among biofilm producing isolates compared to non-biofilm producing isolates. Multidrug resistance was most significant among non-biofilm producers (24.0%) than biofilm producers (20.0%). Extensively-Drug resistance and Pandrug resistance were more pronounced among biofilm-producing isolates (20.0% and 10.0% respectively) than the non-biofilm producers (2.0% and 4.0% respectively). Relationship between biofilm formation and multiple drug resistance among isolates was statistically significant (f=5.0; p=.026336; p>.05).

Furthermore, biofilm-producing strains of *Staphylococcus aureus* and *Pseudomonas aeruginosa* were predominantly XDR (8.0% and 10.0% respectively), biofilm producing strains of *Escherichia coli* were predominantly PDR, and that of *K. pneumoniae* and *Proteus* Spp were mostly MDR respectively.
Overall resistance pattern of isolates against the antimicrobial drugs tested has shown that the highest resistance rate was against Gentamicin and Streptomycin. *Staphylococcus aureus* were highly resistant to STR and CIP, *K. pneumoniae* were resistant against GEN, SXT, AMP, OFX; *E. coli* were resistant against GEN, STR, SXT, PEF, OFX; *P. aeruginosa* were resistant against GEN, STR, CIP, SPX, CHL; and *Proteus* spp were resistant against GEN, PEF, AMC, CHL (Fig. 2).

Acquired resistance profile of biofilm-producing isolates has shown that 31.25% were MDR and XDR respectively, while 15.625% were PDR (Table IV).

Resistivity pattern of biofilm-producing isolates has shown that *Staphylococcus aureus* were observed to be highly resistant to Ciprofloxacin (85.7%), *Klebsiella pneumoniae* were highly resistant to Ofloxacin and Sparfloxacin (83.3% respectively), *Escherichia coli* were completely resistant to Ofloxacin (100%), *Pseudomonas aeruginosa* were completely resistant to Gentamicin, Streptomycin, Ciprofloxacin and Chloramphenicol (100%), and *Proteus* spp were highly resistant to Amoxiclav, Gentamicin, Pefloxacin, Ofloxacin, Chloramphenicol and Sparfloxacin (83.3% respectively) (Table V).

### Table III: Acquired Resistance Profile of Biofilm Producing and Non-Biofilm Producing Clinical Bacterial Isolates Examined

| Bacterial isolates          | Biofilm producing Acquired Resistance | Biofilm producing (%) | Non-biofilm producing (%) | Total (%) |
|-----------------------------|---------------------------------------|-----------------------|---------------------------|-----------|
|                             | MDR | XDR | PDR | MDR | XDR | PDR |                  |
| *Staphylococcus aureus*     | 3 (6.0) | 4 (8.0) | 0 (0.0) | 3 (6.0) | 0 (0.0) | 0 (0.0) | 10 (20.0) |
| *Klebsiella pneumoniae*     | 3 (6.0) | 0 (0.0) | 0 (0.0) | 4 (8.0) | 0 (0.0) | 0 (0.0) | 7 (14.0) |
| *Escherichia coli*          | 0 (0.0) | 1 (2.0) | 3 (6.0) | 0 (0.0) | 1 (2.0) | 1 (2.0) | 6 (12.0) |
| *Pseudomonas aeruginosa*    | 1 (2.0) | 5 (10.0) | 0 (0.0) | 4 (8.0) | 0 (0.0) | 0 (0.0) | 10 (20.0) |
| *Proteus* spp               | 3 (6.0) | 0 (0.0) | 2 (4.0) | 1 (2.0) | 0 (0.0) | 1 (2.0) | 7 (14.0) |
| **Total (%)**               | 10 (20.0) | 10 (20.0) | 5 (10.0) | 12 (24.0) | 1 (2.0) | 2 (4.0) | 40 (80.0) |

**Fig. 2. Resistivity profile of the clinical bacterial isolates examined.** Isolates were highly resistant to Streptomycin and Gentamicin. *S. aureus* isolates were highly resistant to GEN and CIP, and so were *Pseudomonas aeruginosa* isolates.
IV. DISCUSSION

Antimicrobial resistance renders antibiotics that were once a breakthrough in the treatment of infectious diseases, ineffective and diseases that were once treatable have become difficult to treat. More so, clinical bacterial isolates have now developed the capacity to become resistant to multiple antibiotics of different classes. In this study, four-fifth of the clinical bacterial isolates examined were resistant to at least three antimicrobial drugs of different classes, giving rise to typical multidrug resistant strains. A similar pattern was observed by [19] in a research conducted in Ethiopia. While trying to look at the possible cause of multiple resistance, they found out that more than 50% of the gram-negative bacteria isolated harboured extended-spectrum beta-lactamases (ESBL) and/or AmpC.

A significant majority of clinical bacterial isolates examined in this study have been found to produce biofilms. It was observed to be more common among Staphylococcus aureus and Pseudomonas aeruginosa isolates. This is similar to the reports of [20]. They concluded that biofilm formation is a heterogeneous property amongst clinical strains and is associated with bacterial specie and certain clonal types.

Staphylococcus aureus biofilm is a multilayered biofilm embedded within a glycocalyx or slime layer of the glycocalyx as primarily composed of teichoic acids and Staphylococcal host proteins [21]. Staphylococcal infections that have demonstrated a biofilm component include Osteomyelitis (where S. aureus attaches to localized areas of trauma on the bone and divides by binary fission to form an early biofilm) [22], chronic wound infections such as diabetic foot ulcers, venous stasis ulcers and pressure sores [23] and polymicrobial biofilm infections, an example include S. aureus favorably binding to the hyphal form of C. albicans and develop biofilm [24].

It was also observed in this study, that isolates recovered from Urine samples exhibited the highest biofilm formation rate. This is an important finding in the understanding that biofilm formation has been associated with specific clonal types and sites of bacterial isolation [20]. A previous study conducted by [25] revealed similar findings after varying pH and Fe³⁺ concentration in relation to the site of bacterial isolation. They affirmed that biofilm formation among Streptococcus pneumoniae serotype 3 clinical isolates was determined by the site of isolation and is affected by changes in pH and Fe³⁺ concentration.

The presence of biofilm-producing bacteria in the urine has implications on the prognosis of a possible urinary tract infection. Such infection can lead to pyelonephritis [26] and/or chronic bacterial prostatitis. Diagnosis of the latter is quite difficult because the bacteria cannot be detected in the prostatic secretion or urine of patients [27] (possibly because they exist as biofilms and not in planktonic form). Catheter-associated urinary tract infections (CAUTIs) are also associated with biofilm-forming bacteria, where most infections have been observed to be monomicrobial [28]. Treatment of such diseases can pose a therapeutic challenge due to the ability of the pathogens to exist as biofilm, with marked resistance to antimicrobial drugs.

Analysis of acquired resistance profile of biofilm-producing isolates in this study revealed that a significant majority of the isolates were multidrug resistant (MDR) and extensively drug resistant (XDR), while the rest were Pandrug resistant (PDR). Biofilm-producing bacteria have been associated with a high rate of multiple drug resistance. That is why biofilm-based infections tend to be refractory, exceptionally difficult to treat and can lead to chronic infections with fatal consequences. This becomes more worrisome when such an infection occurs in immunocompromised individuals.

The scourge of multiple drug resistance is quite prevalent among a wide spectrum of pathogenic bacteria. Such multiple resistance is usually acquired and can be attributed, in most cases, to horizontal transfer of multiple resistance genes carried on plasmids. However, another factor that can contribute to such an extensive resistance capacity is the ability to form biofilm, as results of this study has demonstrated. So many explanations have been given with regards to why biofilm producing bacteria are more resistant than planktonic strains [9], [10], [11], [12], [13], [14]. However, further studies is required to examine the biofilm physiology with a view to unearth the mechanisms...
involved. Understanding such processes can serve as a guide towards drug design by identifying possible target site(s) for antimicrobial activity.

However, a limitation of this study is in the fact that biofilm formation was studied on a single-specie basis. In most cases, biofilm is a multispecie community where interactions can modulate the overall antimicrobial tolerance level. Such interactions are relevant in both biofilm and planktonic infections given the polymicrobial nature of most infections.

V. CONCLUSION

We found a high biofilm formation rate among clinical bacterial isolates. *Staphylococcus aureus* and *Pseudomonas aeruginosa* were observed to be the predominant biofilm producers. Isolates derived from Urine samples were the most significant biofilm producers. We also observed that biofilm-producing isolates have a highly reduced/non-susceptibility to multiple antimicrobial drugs. Extreme forms of multiple drug resistance (XDR and PDR) were found predominantly among biofilm producing strains of a bacterial specie.
