Almost Periodic Solutions of Evolution Differential Equations with Impulsive Action

Viktor Tkachenko

Abstract In an abstract Banach space we study conditions for the existence of piecewise continuous, almost periodic solutions for semilinear impulsive differential equation with fixed and non-fixed moments of impulsive action.

1 Introduction

We consider the problem of the existence of piecewise continuous, almost periodic solutions for the nonlinear impulsive differential equation

\[
\frac{du}{dt} + (A + A_1(t))u = f(t,u), \quad t \neq \tau_j(u),
\]

where \(u : \mathbb{R} \to X\), \(X\) is a Banach space, \(A\) is a sectorial operator in \(X\), \(A_1(t)\) is some operator-value function, \(\{B_j\}\) is a sequence of some closed operators, and \(\{\tau_j(u)\}\) is an unbounded and strictly increasing sequence of real numbers for all \(u\) from some domain of space \(X\).

We use the concept of piecewise continuous almost periodic functions proposed in [7]. Points of discontinuities of these functions coincide to points of impulsive actions \(\{\tau_j\}\). We mention the remarkable paper [19], where a number of important statements about almost periodic pulse system was proved. Then these results were included in the well-known monograph [18]. Today there are many articles related to the study of almost periodic impulsive systems (see, for example, [1, 2, 3, 12, 13, 15, 21, 22, 24]). In the papers [8, 23, 27, 28] almost periodic solutions for abstract impulsive differential equations in the Banach space are investigated.
In this paper, we consider the semilinear abstract impulsive differential equation in a Banach space with sectorial operator in the linear part of the equation and some closed operators in linear parts of impulsive action. Using fractional powers of operator \( A \) and corresponding interpolation spaces allows us to consider strong or classical solutions. Note that such equations with periodic right-hand sides were first studied in [17]. In equations with nonfixed moments of impulsive action, points of discontinuity depend on solutions; that is, every solution has its own points of discontinuity. Moreover, a solution can intersect the surface of impulsive action several times or even an infinite number of times. This is the so-called pulsation or beating phenomenon. We will assume that solutions of (1), (2) don’t have beating at the surfaces \( t = \tau_j(u) \); in other words, solutions intersect each surface no more than once.

For impulsive systems in the finite-dimensional case, there are several sufficient conditions that allow us to exclude the phenomenon of pulsation (see, [18], [20]). In infinite dimensional case analogous conditions cannot easily be verified. In every concrete case one needs a separate investigation.

We assume that the corresponding linear homogeneous equation has an exponential dichotomy. The definition of exponential dichotomy for an impulsive evolution equation corresponds to the definition of exponential dichotomy for continuous evolution equations in an infinite-dimensional Banach space [5, 9, 16]. We require that only solutions of a linear system from an unstable manifold can be unambiguously extended to the negative semiaxis.

Robustness is an impotent property of the exponential dichotomy [5, 10, 16]. We mention the papers [4, 14, 25, 26] where the robustness of the exponential dichotomy for impulsive systems by small perturbations of right-hand sides is proved. In this chapter we prove robustness of the exponential dichotomy also by the small perturbation of points of impulsive action. We use a change of time in the system. Then approximation of the impulsive system by difference systems (see [9]) can be used. If a linear homogeneous equation is exponentially stable, we prove stability of the almost periodic solution of nonlinear equation (1), (2). Following [17], we use the generalized Gronwall inequality, taking into account singularities in integrals and impulsive influences.

This chapter is organized as follows. In Sect.7.2 we present some preliminary definitions and results. In Sect.7.3, we study an exponential dichotomy of impulsive linear equations. Section 7.4 is devoted to studying the existence and stability of almost periodic solutions in linear inhomogeneous equations with impulsive action and semilinear impulsive equations with fixed moments of impulsive action. In Sect.7.5 we consider impulsive evolution equations with nonfixed moments of impulsive action. In Sect.7.6 we discuss the case of unbounded operators \( B_j \) in linear parts of impulsive action.
2 Preliminaries

Let \((X, \|\cdot\|)\) be an abstract Banach space and \(R\) and \(Z\) be the sets of real and integer numbers, respectively.

We will consider the space \(\mathcal{P}(J,X)\), \(J \subset R\), of all piecewise continuous functions \(x: J \rightarrow X\) such that

i) the set \(\{\tau_j \in J : \tau_{j+1} > \tau_j, j \in Z\}\) of discontinuities of \(x\) has no finite limit points;

ii) \(x(t)\) is left-continuous \(x(\tau_j - 0) = x(\tau_j)\) and there exists \(\lim_{t\to\tau_j^-} x(t) = x(\tau_j + 0)\).

We will use the norm \(\|x\|_{PC} = \sup_{t \in J} \|x(t)\|\) in the space \(\mathcal{P}(J,X)\).

**Definition 1.** The integer \(p\) is called an \(\varepsilon\)-almost period of a sequence \(\{x_k\}\) if

\[\|x_{k+p} - x_k\| < \varepsilon\quad \text{for any } k \in Z.\]

The sequence \(\{x_k\}\) is almost periodic if for any \(\varepsilon > 0\) there exists a relatively dense set of its \(\varepsilon\)-almost periods.

**Definition 2.** The strictly increasing sequence \(\{\tau_k\}\) of real numbers has uniformly almost periodic sequences of differences if for any \(\varepsilon > 0\) there exists a relatively dense set of \(\varepsilon\)-almost periods common for all sequences \(\{\tau_k^j\}\), where \(\tau_k^j = \tau_{k+j} - \tau_k, j \in Z\).

By Samoilenko and Trofimchuk [21], the sequence \(\{\tau_k\}\) has uniformly almost periodic sequences of differences if and only if \(\tau_k = ak + c_k\), where \(\{c_k\}\) is an almost periodic sequence and \(a\) is a positive real number.

By Lemma 22 ([18], p. 192), for a sequence \(\{\tau_j\}\) with uniformly almost periodic sequences of differences there exists the limit

\[\lim_{T \to \infty} \frac{i(t,t+T)}{T} = p\]

uniformly with respect to \(t \in R\), where \(i(s, t)\) is the number of the points \(\tau_k\) lying in the interval \((s, t)\). Then for each \(q > 0\) there exists a positive integer \(N\) such that on each interval of length \(q\) there are no more then \(N\) elements of the sequence \(\{\tau_j\}\); that is, \(i(s, t) \leq N(t - s)/q + N\).

Also for sequence \(\{\tau_j\}\) with uniformly almost periodic sequences of differences there exists \(\Theta > 0\) such that \(\tau_{j+1} - \tau_j \leq \Theta, j \in Z\).

**Definition 3.** The function \(\varphi \in \mathcal{P}(R,X)\) is said to be \(W\)-almost periodic if

i) the strictly increasing sequence \(\{\tau_k\}\) of discontinuities of \(\varphi(t)\) has uniformly almost periodic sequences of differences;

ii) for any \(\varepsilon > 0\) there exists a positive number \(\delta = \delta(\varepsilon)\) such that if the points \(t'\) and \(t''\) belong to the same interval of continuity and \(|t' - t''| < \delta\) then \(\|\varphi(t') - \varphi(t'')\| < \varepsilon\);

iii) for any \(\varepsilon > 0\) there exists a relatively dense set \(\Gamma\) of \(\varepsilon\)-almost periods such that if \(\tau \in \Gamma\), then \(\|\varphi(t + \tau) - \varphi(t)\| < \varepsilon\) for all \(t \in R\) that satisfy the condition \(|t - u_k| \geq \varepsilon, k \in Z\).
We consider the impulsive equation \([\text{1}], \text{2}\) with the following assumptions:

(H1) \(A\) is a sectorial operator acting in \(X\) and \( \inf \{ \Re \mu : \mu \in \sigma(A) \} \geq \delta > 0 \), where \( \sigma(A) \) is the spectrum of \(A\). Consequently, the fractional powers of \(A\) are well defined, and one can consider the spaces \(X^\alpha = D(A^\alpha)\) for \(\alpha \geq 0\) endowed with the norms \(\|x\|_\alpha = \|A^\alpha x\|\).

(H2) The function \(A_1(t) : \mathbb{R} \to L(X^\alpha, X)\) is Bohr almost periodic and Hölder continuous, \(\alpha \geq 0\), \(L(X^\alpha, X)\) is the space of linear bounded operators \(X^\alpha \to X\).

(H3) We shall use the notation \(U_\alpha^\rho = \{x \in X^\alpha : \|x\|_\alpha \leq \rho \}\). Assume that the sequence \(\{\tau_j(u)\}\) of functions \(\tau_j : U_\rho^\alpha \to \mathbb{R}\) has uniformly almost periodic sequences of differences uniformly with respect to \(u \in U_\rho^\alpha\) and there exists \(\Theta > 0\) such that \(\inf u \tau_{j+1}(u) - \sup u \tau_j(u) \geq \Theta\) for all \(u \in U_\rho^\alpha\) and \(j \in \mathbb{Z}\). Also, there exists \(\Theta > 0\) such that \(\sup u \tau_{j+1}(u) - \inf u \tau_j(u) \leq \Theta\) for all \(j \in \mathbb{Z}\) and \(u \in U_\rho^\alpha\).

(H4) The sequence \(\{B_j\}\) of bounded operators is almost periodic and there exists \(b > 0\) such that \(\|B_j u\|_\alpha \leq b \|u\|_\alpha\) for \(j \in \mathbb{Z}, \alpha \geq 0\) and \(u \in X^\alpha\).

(H5) The function \(f(t, u) : \mathbb{R} \times U_\rho^\alpha \to X\) is continuous in \(u\) and is locally Hölder continuous and \(W\)-almost periodic in \(t\) uniformly with respect to \(u \in U_\rho^\alpha\).

(H6) The sequence \(\{g_j(u)\}\) of continuous functions \(U_\rho^\alpha \to X^\alpha\) is almost periodic uniformly with respect to \(u \in U_\rho^\alpha\).

Remark 1. Assumption (H4) is satisfied if, for example, \(B_j A = A B_j\) for all \(j \in \mathbb{Z}\). We assume that operators \(B_j\) are bounded. Many of our results are valid if the \(B_j\) are unbounded closed operators \(X^{\alpha+\gamma} \to X^\alpha\) for \(\alpha \geq 0\) and some \(\gamma > 0\). We discuss this case in the last section.

We use the following generalization of Lemma 7 from [7], p. 288 (also, see [6] and [19]):

**Lemma 1.** Assume that a sequence of real numbers \(\{\tau_j\}\) has uniformly almost periodic sequences of differences, the sequence \(\{B_j\}\), \(B_j \in X\), is almost periodic and the function \(f(t) : \mathbb{R} \to X\) is \(W\)-almost periodic. Then for any \(\varepsilon > 0\) there exists a such \(l = l(\varepsilon) > 0\) that for any interval \(J\) of length \(l\) there are such \(r \in J\) and an integer \(q\) that the following relations hold:

\[
|\tau_{i+q} - \tau_i - r| < \varepsilon, \|B_{i+q} - B_i\| < \varepsilon, i \in \mathbb{Z},
\]

\[
\|f(t + r) - f(t)\| < \varepsilon, t \in \mathbb{R}, |t - \tau_j| > \varepsilon, j \in \mathbb{Z}.
\]

If \(A\) is a sectorial operator then \((-A)\) is an infinitesimal generator of the analytical semigroup \(e^{-A t}\). For every \(x \in X^\alpha\) we get \(e^{-A t} A^\alpha x = A^\alpha e^{-A t} x\). Further, we shall use the inequalities (see [19])

\[
\|A^\alpha e^{-A t}\| \leq C_at^{-\alpha} e^{-\delta t}, t > 0, \alpha > 0,
\]

\[
\|(e^{-A t} - I) u\| \leq \frac{1}{\alpha} C_\alpha t^{-\alpha} \|A^\alpha u\|, t > 0, \alpha \in (0, 1], u \in X^\alpha,
\]

where \(C_\alpha \in \mathbb{R}\) is nonnegative and bounded as \(\alpha \to +0\).
Almost periodic evolution equations

**Definition 4.** The function \( u(t) : [t_0, t_1] \to X^\alpha \) is said to be a solution of the initial value problem \( u(t_0) = u_0 \in X^\alpha \) for Eq. (1), (2) on \([t_0, t_1]\) if

(i) it is continuous in \([t_0, \tau_k], (\tau_k, \tau_{k+1}], \ldots, (\tau_{k+s}, t_1]\) with the discontinuities of the first kind at the moments \( t = \tau_j \) of intersections with impulsive surfaces;

(ii) \( u(t) \) is continuously differentiable in each of the intervals \((t_0, \tau_k), (\tau_k, \tau_{k+1}), \ldots, (\tau_{k+s}, t_1)\) and satisfies Eqs. (1) and (2) if \( t \in (t_0, t_1), t \neq \tau_j, \) and \( t = \tau_j \), respectively;

(iii) the initial-value condition \( u(t_0) = u_0 \) is fulfilled.

We assume that solutions \( u(t) \) of (1), (2) are left-hand-side continuous, hence \( u(\tau_j) = u(\tau_j - 0) \) at all points of impulsive action.

Also we assume that in the domain \( U_{\beta}^\alpha \) solutions of (1) and (2) don’t have beating at the surfaces \( t = \tau_j(u) \); in other words, solutions intersect each surface no more then once.

### 3 Exponential Dichotomy

Together with Eq. (1), (2) we consider the corresponding linear homogeneous equation

\[
\frac{du}{dt} + (A + A_1(t))u = 0, \quad t \neq \tau_j, \tag{4}
\]
\[
\Delta u|_{t=\tau_j} = u(\tau_j + 0) - u(\tau_j) = B_j u(\tau_j), \quad j \in \mathbb{Z}, \tag{5}
\]

where \( \tau_j = \tau_j(0) \). Denote by \( V(t, s) \) the evolution operator of the linear equation without impulses (4). It satisfies \( V(\tau, \tau) = I \), \( V(t, s)V(s, \tau) = V(t, \tau), \) \( t \geq s \geq \tau \).

By Theorem 7.1.3 ([9], p.190), \( V(t, \tau) \) is strongly continuous with values in \( L(X^\beta) \) for any \( 0 \leq \beta < 1 \) and

\[
||V(t, \tau)x||_\beta \leq L_Q(t - \tau)^{(\gamma - \beta)_{-}}||x||_{\gamma}, \tag{6}
\]

where \((\gamma - \beta)_{-} = \min(\gamma - \beta, 0), t - \tau \leq Q, L_Q = L_Q(Q)\). Moreover,

\[
||V(t, \tau)x - x||_\beta \leq L_Q(t - \tau)^{\nu}||x||_{\beta + \nu}, \quad \nu > 0, \beta + \nu \leq 1. \tag{7}
\]

Using the proof of Lemma 7.1.1 from [9], p. 188, one can verify the following generalized Gronwall inequality

**Lemma 2.** Suppose \( 0 \leq \alpha, \beta < 1, a_1 \geq 0, a_2 \geq 0, b \geq 0, 0 < Q < \infty \) and \( y(t) \) is non-negative function locally integrable on \( 0 \leq t < Q \) with

\[
y(t) \leq a_1 + a_2 t^{-\alpha} + b \int_0^t (t - s)^{\alpha - \beta} y(s) ds
\]
on this interval; then there is a constant \( \tilde{C} = \tilde{C}(\beta, b, Q) < \infty \) such that
\[
y(t) \leq \left( a_1 + \frac{a_2}{(1-\alpha)^\alpha} \right) \tilde{C}(\beta, b, Q).
\]  
(8)

Note that inequality (8) can be rewritten as

\[
y(t) \leq \left( a_1 + \frac{a_2}{\alpha} \right) \tilde{C}_1, \quad \tilde{C}_1 = \frac{\tilde{C}(\beta, b, Q)}{1-\alpha}.
\]  
(9)

We will use the following perturbation lemma.

**Lemma 3.** Let us consider the perturbed equation

\[
\frac{du}{dt} + (\gamma A + A_2(t))u = 0,
\]  
(10)

where \( \gamma = \text{Const} > 0, A_2(t) : R \to L(X^\alpha, X) \).

Then for \( Q > 0 \), there exists \( \varepsilon_0 > 0 \) such that for all \( \varepsilon \leq \varepsilon_0 \) and \( |\gamma - 1| \leq \varepsilon \), \( \sup_{t} \|A_1(t) - A_2(t)\|_{L(X^\alpha, X)} \leq \varepsilon \) the evolution operators \( V(t, s) \) of (11) and \( V_1(t, s) \) of (10) satisfy

\[
\|V(t, s) - V_1(t, s)\|_a \leq R_1(\varepsilon), \quad t - s \leq Q,
\]  
(11)

with \( R_1(\varepsilon) \) depends on \( Q, \alpha \), and \( R_1(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

**Proof.** For definiteness let \( \gamma > 1 \). Solutions \( x(t) \) and \( y(t) \) of Eqs. (4) and (10) satisfy the following integral equations

\[
x(t) = e^{-A(t-t_0)}x_0 + \int_{t_0}^{t} e^{-A(t-s)}A_1(s)x(s)ds
\]

and

\[
y(t) = e^{-\gamma A(t-t_0)}x_0 + \int_{t_0}^{t} e^{-\gamma A(t-s)}A_2(s)y(s)ds.
\]

Then

\[
\|x(t) - y(t)\|_\alpha \leq \|\left(I - e^{-A(\gamma - 1)(t-t_0)}\right)A^\alpha e^{-A(t-t_0)}x_0\|
\]

\[
+ \int_{t_0}^{t} \|\left(I - e^{-A(\gamma - 1)(t-s)}\right)A^\alpha e^{-A(t-s)}A_1(s)x(s)\|ds
\]

\[
+ \int_{t_0}^{t} A^\alpha e^{-\gamma A(t-s)}(A_1(s) - A_2(s))x(s)\|ds
\]

\[
+ \int_{t_0}^{t} A^\alpha e^{-\gamma A(t-s)}A_2(s)(x(s) - y(s))\|ds
\]

\[
\leq a_1(\varepsilon)\|x_0\|_\alpha + a_2 \int_{t_0}^{t} (t-s)^{-\alpha}\|x(s) - y(s)\|_\alpha ds,
\]

where \( a_2 = C_\alpha \sup_{t} \|A_1(s)\|_{L(X^\alpha, X)} \) and \( a_1(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \). By Lemma 2, there exists positive constant \( K_1 \) depending on \( \alpha \) and \( Q \) such that
\[ \| x(t) - y(t) \|_{\alpha} \leq K_1 a_1(\varepsilon) \| x_0 \|_{\alpha} = R_2(\varepsilon) \| x_0 \|_{\alpha}. \]

**Lemma 4.** Let us consider Eq. (4) and
\[ \frac{dv}{dt} + (A + A_2(t))v = 0, \quad (12) \]
such that \( A_2 : R \to L(X^\alpha, X) \) is a bounded and Hölder continuous function.
Then for \( Q > 0 \), there exists \( \varepsilon_0 > 0 \) such that for all \( \varepsilon \leq \varepsilon_0 \) and
\[ \sup_t \| A_1(t) - A_2(t) \|_{L(X^\alpha, X)} \leq \varepsilon \]
the evolution operators \( V(t, s) \) of (4) and \( V_1(t, s) \) of (12) satisfy
\[ \| (V(t, s) - V_1(t, s))u \|_{\alpha} \leq R_3(\varepsilon) \| t - t_0 \|^{1-2\alpha + \delta} \| u \|_{\delta}, \quad t - s \leq Q, \quad (13) \]
with \( R_3(\varepsilon) = R_3(\varepsilon, Q, \alpha) \) and \( R_3(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

**Proof.** Denote by \( u(t) \) and \( v(t) \) solutions of (4) and (12) with initial value \( u(t_0) = v(t_0) = u_0 \). They satisfy inequalities
\[
\begin{align*}
& \| u(t) - v(t) \|_{\alpha} \leq \int_{t_0}^{t} \| A^\alpha e^{-A(t-s)}(A_1(s) - A_2(s))u(s) \| ds \\
& \quad + \int_{t_0}^{t} \| A^\alpha e^{-A(t-s)}A_2(s)(u(s) - v(s)) \| ds \\
& \leq C_a Q \| u_0 \|_{\delta} \int_{t_0}^{t} \frac{ds}{(t-s)^\alpha (s-t_0)^{\alpha-\delta}} + C_a \| A_1 \|_{L} \int_{t_0}^{t} \frac{\| u(s) - v(s) \|_{\alpha} ds}{(t-s)^\alpha} \\
& \leq \varepsilon \| u_0 \|_{\delta} R_4 + C_a \| A_1 \|_{L} \int_{t_0}^{t} \frac{\| u(s) - v(s) \|_{\alpha} ds}{(t-s)^\alpha}. \quad (14)
\end{align*}
\]

Applying Lemma 2 to (14), we obtain (13).

We define the evolution operator for equation (4), (5) as
\[ U(t, s) = V(t, s) \text{ if } \tau_k < s \leq \tau_{k+1} \]
and
\[ U(t, s) = V(t, \tau_k) (I + B_k)V(\tau_k, \tau_{k-1}) \ldots (I + B_m)V(\tau_m, s), \quad (15) \]
if \( \tau_{m-1} < s \leq \tau_m < \tau_{m+1} < \ldots < \tau_k < t \leq \tau_{k+1} \).

It is easy to verify that for fixed \( t > s \) the operator \( U(t, s) \) is bounded in the space \( X^\alpha \).

**Definition 5.** We say that the equation (4)–(5) has an exponential dichotomy on \( R \) with exponent \( \beta > 0 \) and bound \( M \geq 1 \) (with respect to the space \( X^\alpha \)) if there exist projections \( P(t), t \in R \), such that
(i) \( U(t,s)P(s) = P(t)U(t,s) , \ t \geq s ; \)

(ii) \( U(t,s)_{|_{\text{Im}(P(s))}} \) for \( t \geq s \) is an isomorphism on \( \text{Im}(P(s)) \), and then \( U(s,t) \) is defined as an inverse map from \( \text{Im}(P(t)) \) to \( \text{Im}(P(s)) \);

(iii) \( \| U(t,s)(1 - P(s))u \|_{\alpha} \leq M e^{-B(t-s)} \| u \|_{\alpha} , \ t \geq s , \ u \in X_{\alpha} ; \)

(iv) \( \| U(t,s)P(s) \|_{\alpha} \leq Me^{B(t-s)} \| u \|_{\alpha} , \ t \leq s , \ u \in X_{\alpha} . \)

If Eq. (4)–(5) has an exponential dichotomy on \( R \), then the nonhomogeneous equation

\[
\frac{du}{dt} + (A + A_{1}(t))u = f(t) , \quad t \neq \tau_{j} ,
\]

\[
\Delta u|_{t=\tau_{j}} = u(\tau_{j} + 0) - u(\tau_{j}) = B_{j}u(\tau_{j}) + g_{j} , \quad j \in Z ,
\]

has a unique solution bounded on \( R \)

\[
u_{0}(t) = \int_{-\infty}^{t} G(t,s)f(s)ds + \sum_{j \in \mathbb{Z}} G(t,\tau_{j} + 0)g_{j} ,
\]

where

\[
G(t,s) = \begin{cases} U(t,s)(I - P(s)) , & t \geq s , \\
-U(t,s)P(s) , & t < s , 
\end{cases}
\]

is the Green function such that

\[
\| G(t,s)u \|_{\alpha} \leq M e^{-B(t-s)} \| u \|_{\alpha} , \ t , s \in R .
\]

Analogous to [9], p.250, it can be proven that a function \( u(t) \) is a bounded solution of \( (16) , (17) \) on the semiaxis \( [t_{0},+\infty) \) if and only if \( u(t) = \)

\[
U(t,t_{0})(I - P(t_{0}))u(t_{0}) + \int_{t_{0}}^{t_{0}+\infty} G(t,s)f(s)ds + \sum_{t_{0} \leq \tau_{j}} G(t,\tau_{j} + 0)g_{j} , \ t \geq t_{0} .
\]

A function \( u(t) \) is bounded solution on the semiaxis \( (-\infty,t_{0}) \) if and only if

\[
u(t) = U(t,t_{0})P(t_{0})u(t_{0}) + \int_{-\infty}^{t_{0}} G(t,s)f(s)ds + \sum_{t_{0} \geq \tau_{j}} G(t,\tau_{j} + 0)g_{j} , \ t \leq t_{0} .
\]

Now we estimate \( \| G(t,s)u \|_{\alpha} \) for \( u \in X \). Let \( t > s \) and \( \tau_{m-1} < s \leq \tau_{m} , \ \tau_{k} < t \leq \tau_{k+1} \). Then

\[
\| G(t,s)u \|_{\alpha} = \| U(t,s)(I - P(s))u \|_{\alpha}
\leq \| U(t,\tau_{m})(I - P(\tau_{m})) \|_{\alpha} \| U(\tau_{m},s)u \|_{\alpha}
\leq Me^{-B(t-s)}L_{\Theta}(\tau_{m} - s)^{-\alpha} \| u \| \leq M e^{-B(t-s)} |\tau_{m} - s|^{-\alpha} \| u \|
\]

and
Almost periodic evolution equations

\[ \| G(s,t)u \|_a = \| U(s,t)P(t)u \|_a \]
\[ \leq \| U(s,t + 1)P(t + 1) \|_a A^{\alpha}U(t + 1,t)u \| \leq \bar{M} e^{-\bar{\beta}(t-s)} \| u \|. \]  \( (21) \)

If \( t_1 \) and \( t_2 \) belong to the same interval of continuity, then
\[ \| P(t_1)u - P(t_2)u \|_\gamma \leq \bar{M}_1 \| t_1 - t_2 \|^\gamma \| u \| \]  \( (22) \)

since as in \( [9] \), p.247,
\[ \| P(t + h)u - P(t)u \|_\gamma \leq \| P(t)u - V(t + h,t)P(t)u \|_\gamma \]
\[ + \| V(t + h,t)P(t)u - P(t + h)u \|_\gamma \]
\[ \leq \| (I - V(t + h,t))P(t)u \|_\gamma + \| P(t + h)(V(t + h,t)u - u) \|_\gamma. \]

**Lemma 5.** Let the impulsive equation \( (2), (3) \) is exponentially dichotomous with positive constants \( \bar{\beta} \) and \( M \). Then there exists \( \varepsilon > 0 \) such that the perturbed equations

\[ \frac{du}{dt} + (A + \bar{A}(t))u = 0, \quad t \neq \bar{\tau}_j, \]  \( (23) \)
\[ \Delta u_{\mid t = \bar{\tau}_j} = u(\bar{\tau}_j + 0) - u(\bar{\tau}_j) = \bar{B}_j u(\bar{\tau}_j), \quad j \in \mathbb{Z}, \]  \( (24) \)

with \( \sup_j |\tau_j - \bar{\tau}_j| \leq \varepsilon, \sup_j \|B_j - \bar{B}_j\| \leq \varepsilon, \sup_j \|A_1(t) - \bar{A}(t)\|_{L\left(\mathbb{R}^N, \mathbb{R}^N\right)} \leq \varepsilon \), are also exponentially dichotomous with some constants \( \beta_1 \leq \bar{\beta} \) and \( M_1 \geq M \).

**Proof.** In Eq. \( (4), (5) \), we introduce the change of time \( t = \vartheta(t') \) such that \( \tau_j = \vartheta(\bar{\tau}_j), j \in \mathbb{Z} \), and the function \( \vartheta \) is continuously differentiable and monotonic on each interval \( \left( \bar{\tau}_j, \bar{\tau}_{j+1} \right) \).

The function \( \vartheta \) can be chosen in piecewise linear form
\[ t = a_j t' + b_j, \quad a_j = \frac{\tau_{j+1} - \bar{\tau}_j}{\bar{\tau}_{j+1} - \bar{\tau}_j}, \quad b_j = \frac{\tau_j \bar{\tau}_{j+1} - \tau_{j+1} \bar{\tau}_j}{\bar{\tau}_{j+1} - \bar{\tau}_j} \quad \text{if} \quad t' \in (\bar{\tau}_j, \bar{\tau}_{j+1}). \]  \( (25) \)

The function \( \vartheta(t') \) satisfies the conditions
\[ |\vartheta(t') - t'| \leq \varepsilon, \quad \left| \frac{d \vartheta(t')}{dt'} - 1 \right| \leq 2\varepsilon / \vartheta. \]

The equation \( (4), (5) \) in the new coordinates \( v(t') = u(\vartheta(t')) \) has the form
\[ \frac{dv}{dt'} + \frac{d \vartheta(t')}{dt'} (A + A_1(\vartheta(t'))) v = 0, \quad t \neq \bar{\tau}_j, \]  \( (26) \)
\[ \Delta v_{\mid t = \bar{\tau}_j} = v(\bar{\tau}_j + 0) - v(\bar{\tau}_j) = B_j v(\bar{\tau}_j), \quad j \in \mathbb{Z}. \]  \( (27) \)

Eq. \( (26), (27) \) has the evolution operator \( U_1(t', t) = U(\vartheta(t'), \vartheta(t)) \). If Eq. \( (4), (5) \) has an exponential dichotomy with projector \( P(t) \) at point \( t \), then Eq. \( (26), (27) \) has an exponential dichotomy with projector \( P_1(t') = P(\vartheta(t')) \) at point \( t' \). Really,
The inequality for an unstable manifold is proved analogously.

The linear equations (26), (27) and (23), (24) have the same points of impulsive actions \( \tilde{t}_j, j \in \mathbb{Z} \), and

\[
\| \frac{d}{dt} \tilde{t} \| \leq \| \frac{d}{dt} \nu \| \leq \| \frac{d}{dt} \tilde{t} \| - \tilde{A}(t') \| \leq \| \nu - \tilde{A}(t') \| \leq K_2(\epsilon),
\]

where \( K_2(\epsilon) \to 0 \) as \( \epsilon \to 0 \).

Let \( \tilde{U}(t', s') \) be the evolution operator for Eq. (23), (24). To show that for sufficiently small \( \delta_0 > 0 \), Eq. (23), (24) is exponentially dichotomous, we use the following variant of Theorem 7.6.10, [9]:

Assume that the evolution operator \( U_1(t', s') \) has an exponential dichotomy on \( R \) and satisfies

\[
\sup_{0 \leq t' - s' \leq \delta} \| U_1(t', s') \| \alpha < \infty
\]

for some positive \( \delta \). Then there exists \( \eta > 0 \) such that

\[
\| \tilde{U}(t', s') - U_1(t', s') \| \alpha < \eta, \text{ whenever } t - s \leq \delta;
\]

the evolution operator \( \tilde{U}(t', s') \) also has an exponential dichotomy on \( R \) with some constants \( \beta_1 \leq \beta, M_1 \geq M \).

To prove this statement, we set for \( n \in \mathbb{Z} \)

\[
t_n = s' + dn, \quad T_n = U_1(s' + d(n + 1), s' + dn + 0), \quad \tilde{T}_n = \tilde{U}(s' + d(n + 1), s' + dn + 0).
\]

If the evolution operator \( U_1(t, s) \) has an exponential dichotomy, then \( \{ T_n \} \) has a discrete dichotomy in the sense of [9] Definition 7.6.4.

According to Henry [9], Theorem 7.6.7, there exists \( \eta > 0 \) such that \( \{ \tilde{T}_n \} \) with

\[
\sup_{n} \| T_n - \tilde{T}_n \| \alpha \leq \eta \text{ has a discrete dichotomy.}
\]

Now we are in the conditions of [9], Exercise 10, p. 229–230 (see also a more general statement [5], Theorem 4.1), what finishes the proof.

Let us estimate the difference \( \| \tilde{T}_k - T_k \| \alpha \). There exists a positive integer \( N \) such that each interval of length \( d \) contains no more then \( N \) elements of sequence \( \{ \tau_j \} \).

Let the interval \( (\zeta_m, \zeta_{m+1}] \) contains points of impulses \( \tilde{\tau}_m, \ldots, \tilde{\tau}_k \) where \( k - m \leq N \). Denote by \( V_1(t, s) \) and \( \tilde{V}(t, s) \) the evolution operators of equations without impulses (26) and (23), respectively. Then

\[
\| T_n - \tilde{T}_n \| \alpha = \| U_1(\xi_{n+1}, \xi_n) - \tilde{U}(\xi_{n+1}, \xi_n) \| \alpha
\]

\[
\leq \| V_1(\xi_{n+1}, \tilde{\xi}_n) - \tilde{V}(\xi_{n+1}, \tilde{\xi}_n)(I + B_k)V_1(\xi_{n+1}, \tilde{\xi}_n) - (I + B_m)V_1(\xi_{n+1}, \tilde{\xi}_n) \| \alpha
\]

\[
+ \| \tilde{V}(\xi_{n+1}, \tilde{\xi}_n)(B_k - B_m)V_1(\xi_{n+1}, \tilde{\xi}_n) - (I + B_m)V_1(\tilde{\xi}_n, \tilde{\xi}_n) \| \alpha + ...
\]
Almost periodic evolution equations

\[ + \|V(\xi_{k+1}, \xi_k)(I + B_k)V(\xi_k, \xi_{k-1}) \ldots (I + B_m)(V(\xi_m, \xi_n) - V(\xi_n, \xi_n))\|_\alpha. \] (29)

Using (11), we get that

\[ \sup \| T_n - \tilde{T}_n \|_\alpha \leq K_3(\varepsilon) \]

with \( K_3(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

The exponentially dichotomous equation (23), (24) has Green’s function

\[ \tilde{G}(t, s) = \begin{cases} \tilde{U}(t, s)(I - \tilde{P}(s)), & t \geq s, \\ -\tilde{U}(t, s)\tilde{P}(s), & t < s, \end{cases} \]

such that

\[ \| \tilde{G}(t, s)u \|_\alpha \leq M_1 e^{-\beta_1|t-s|} \| u \|_\alpha, \quad t, s \in \mathbb{R}, \quad u \in X^\alpha. \]

The sequence of bounded operators \( T_n : X^\alpha \to X^\alpha \) defines the difference equation

\[ u_{n+1} = T_n u_n, \quad n \in \mathbb{Z}, \] (30)

with evolution operator \( T_{n,m} = T_{n-1} \ldots T_m, \ n \geq m, \ T_{m,m} = I \). It is exponentially dichotomous with Green’s function

\[ G_{n,m} = \begin{cases} T_{n,m}(I - P_m), & n \geq m, \\ -T_{n,m}P_m, & n < m, \end{cases} \]

where \( P_m = P(\xi_m) \). The second difference equation

\[ u_{n+1} = \tilde{T}_n u_n, \quad n \in \mathbb{Z}, \] (31)

has evolution operator \( \tilde{T}_{n,m} = \tilde{T}_{n-1} \ldots \tilde{T}_m, \ n \geq m, \ \tilde{T}_{m,m} = I \).

By sufficiently small \( \sup \| T_n - \tilde{T}_n \|_\alpha \), Eq. (31) is exponentially dichotomous with Green’s function

\[ \tilde{G}_{n,m} = \begin{cases} \tilde{T}_{n,m}(I - \tilde{P}_m), & n \geq m, \\ -\tilde{T}_{n,m}\tilde{P}_m, & n < m, \end{cases} \]

According to Henry [9], p. 233, the difference between two Green’s functions satisfies equality

\[ \tilde{G}_{n,m} - G_{n,m} = \sum_{k \in \mathbb{Z}} G_{n,k+1}(\tilde{T}_k - T_k)\tilde{G}_{k,m} \] (32)

and estimation

\[ \| \tilde{G}_{n,m} - G_{n,m} \|_\alpha = M_2 e^{-\beta_2|n-m|} \sup_k \| \tilde{T}_k - T_k \|_\alpha, \quad n, m \in \mathbb{Z}, \] (33)

with some constants \( \beta_2 \leq \beta_1, M_2 \geq M_1 \).
Now we can consider the difference of two Green’s functions $G(t, s) - G_1(t, s)$. Let $t = s + nd + t_1, t_1 \in [0, d)$. Then
\[
\| \tilde{G}(t, s) - G_1(t, s) \|_\alpha \\
= \| \bar{U}(s + nd + t_1, s + nd)\bar{G}(s + nd, s) - U(s + nd + t_1, s + nd)G(s + nd, s) \|_\alpha \\
\leq \| (\bar{U}(s + nd + t_1, s + nd) - U(s + nd + t_1, s + nd))\bar{G}(s + nd, s) \|_\alpha \\
+ \| U(s + nd + t_1, s + nd)(\bar{G}(s + nd, s) - G(s + nd, s)) \|_\alpha.
\]

Using (33) and an estimation of the difference $\bar{U} - U_1$ at a bounded interval as is done in (29), we get
\[
\| \tilde{G}(t, \tau) - G_1(t, \tau) \|_\alpha \leq \bar{M}_2(\varepsilon)e^{-\beta_2|t-\tau|}, \quad t, \tau \in R, \tag{34}
\]
with $\bar{M}_2(\varepsilon) \to 0$ as $\varepsilon \to 0$.

By the definition of Green’s function, we have
\[
\| \bar{P}(t) - P_1(t) \|_\alpha \leq \bar{M}_2(\varepsilon) \quad \text{for all } \tau \in R. \tag{35}
\]

**Corollary 1.** Let the conditions of Lemma 5 be satisfied. Then for $t \in R, |t - \tau_j| \geq \varepsilon, j \in Z$, we have
\[
\| (P(t) - \tilde{P}(t))u\|_\alpha \leq \bar{M}_3(\varepsilon)\|u\|_{\alpha + \nu}, \tag{36}
\]
where $\nu > 0, \alpha + \nu < 1$, and $\bar{M}_3(\varepsilon) \to 0$ as $\varepsilon \to 0$.

**Proof.** Using (22) and (35), we get
\[
\| (P(t) - \tilde{P}(t))u\|_\alpha \leq \| (P(t) - P(\vartheta(t)))u\|_\alpha \\
+ \| (P(\vartheta(t)) - \bar{P}(\vartheta(t)))u\|_\alpha + \| (\bar{P}(\vartheta(t)) - \bar{P}(t))u\|_\alpha \leq \bar{M}_3(\varepsilon)\|u\|_{\alpha + \nu}.
\]

\[\]

**4 Almost Periodic Solutions of Equations with Fixed Moments of Impulsive Action**

Consider the linear inhomogeneous equation
\[
\frac{du}{dt} + (A + A_1(t))u = f(t), \quad t \neq \tau_j, \tag{37}
\]
\[
\Delta u|_{t=\tau_j} = u(\tau_j + 0) - u(\tau_j) = B_j \mu(\tau_j) + g_j, \quad j \in Z. \tag{38}
\]

We assume that

(H7) the function $f(t) : R \to X$ is $W$-almost periodic and locally Hölder continuous with points of discontinuity at moments $t = \tau_j, j \in Z$, at which it is continuous from the left;

(H8) the sequence $\{g_j\}$ of $g_j \in X^{\alpha_1}, \alpha_1 > \alpha > 0$, is almost periodic.
Almost periodic evolution equations

**Theorem 1.** Assume that Eq. \((37), (38)\) satisfy conditions \((H1) - (H3), (H7), and (H8)\) and that the corresponding homogeneous equation is exponentially dichotomous.

Then the equation has a unique \(W\)-almost periodic solution \(u_0(t) \in \mathcal{P} \subset (R, X^\alpha)\).

**Proof.** We show that an almost periodic solution is given by the formula \((38)\). For \(t \in (\tau, \tau + 1]\), it satisfies

\[
\|u_0(t)\|_\alpha \leq \int_{-\infty}^{t} \|A^\alpha U(t, s)(I - P(s))f(s)\|ds \\
+ \int_{t}^{\infty} \|A^\alpha U(t, s)P(s)f(s)\|ds + \sum_{j \in \mathbb{Z}} \|G(t, \tau_j + 0)g_j\|_\alpha \\
\leq \sum_{j \in \mathbb{Z}} \|G(t, \tau_j + 0)g_j\|_\alpha + \int_{t}^{\infty} \|A^\alpha V(t, s)(I - P(s))f(s)\|ds \\
+ \sum_{k \in \mathbb{Z}} \int_{\tau_k}^{\tau_{k+1}} \|U(t, \tau_{k+1})(I - P(\tau_{k+1}))\|_\alpha \|A^\alpha U(t, \tau_{k+1})f(s)\|ds \\
+ \int_{t}^{\tau_1} \|A^\alpha V(t, s)P(s)f(s)\|ds \leq \frac{2M}{1 - e^{-\theta \beta}} \frac{C_0 \Theta^{1-\alpha}}{1 - \alpha} \|f\|_{PC} \\
+ \frac{2M}{1 - e^{-\theta \beta}} \sup_j \|g_j\|_\alpha \leq \tilde{M}_0 \max\{\|f(t)\|_{PC}, \|g_j\|_\alpha\} \tag{39}
\]

with some constant \(\tilde{M}_0 > 0\).

Take an \(\varepsilon\)-almost period \(h\) for the right-hand side of the equation, which satisfies conditions of Lemma 1; that is, there exists a positive integer \(q\) such that \(\tau_j \in (s + h, t + h)\) if \(\tau_j \in (s, t)\) and \(|\tau_j + h - \tau_{j+q}| < \varepsilon, \|B_{j+q} - B_j\| < \varepsilon\).

Let \(t \in (\tau + \varepsilon, \tau_{i+1} - \varepsilon)\). We define points \(\eta_k = (\tau_k + \tau_{k+1})/2, k \in \mathbb{Z}\). Then

\[
\|u_0(t) - u_0(t)\|_\alpha \leq \sum_{j \in \mathbb{Z}} \|G(t + h, \tau_{j+q} + 0)g_{j+q} - G(t, \tau_j + 0)g_j\|_\alpha \\
+ \int_{-\infty}^{\infty} \|G(t + h, s + h)f(s + h) - G(t, s)f(s)\|_\alpha ds \\
\leq \int_{-\infty}^{\infty} \|G(t + h, s + h) - G(t, s)\|_\alpha ds \\
+ \int_{-\infty}^{\infty} \|G(t, s)(f(s + h) - f(s))\|_\alpha ds + \sum_{j \in \mathbb{Z}} \|G(t, \tau_j + 0)(g_{j+q} - g_j)\|_\alpha \\
+ \sum_{j \in \mathbb{Z}} \|G(t + h, \tau_{j+q} + 0) - G(t, \tau_j + 0)\|g_j\|_\alpha. \tag{40}
\]

Denote \(U_2(t) = U(t + h, s + h)\). If \(u(t) = U(t, s)u_0, u(s) = u_0\), is a solution of the impulsive equation \((4), (5)\), then \(u_2(t) = U(t + h, s + h)u_0, u_2(s) = u_0\), is a solution of the equation...
\[
\frac{du}{dt} + (A + A_1(t + h))u = 0, \quad t \neq \tau_j + q - h, \quad (41)
\]
\[
\Delta u|_{t = \tau_j + q} = u(\tau_j + q + 0) - u(\tau_j + q) = B_{j+q}u(\tau_j + q), \quad j \in \mathbb{Z}. \quad (42)
\]

We will use the notation \( V_2(t, s) = V(t, s + h) \) for the evolution operator of the equation without impulses \((41)\). Denote also \( \tilde{\tau}_n = \tau_{n+q} - h, \tilde{B}_n = B_{n+q}. \) Since Eq. \((4), (5)\) is exponentially dichotomous, Eq. \((41), (42)\) is exponentially dichotomous also with projector \( P_2(s) = P(s + h) \).

Let us consider all integrals in \((44)\) separately. By \((36)\) and \((13)\) we have

The first integral in \((40)\) is the sum of two integrals:

\[
\int_{-\infty}^{\infty} \|(G(t + r, s + r) - G(t, s))f(s + r)\|_A ds
\]
\[
= \int_{-\infty}^{t} \|(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)\|_A ds
\]
\[
+ \int_{t}^{\infty} \|(U_2(t, s)P_2(s) - U(t, s)P(s))f(s + r)\|_A ds. \quad (43)
\]

We estimate the first integral in \((43)\); the second integral is considered analogously.

\[
\int_{-\infty}^{t} \|(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)\|_A ds
\]
\[
\leq \int_{\tau_j + \epsilon}^{t} \|A^\alpha(V_2(t, s)(I - P_2(s)) - V(t, s)(I - P(s)))f(s + r)\| ds
\]
\[
+ \int_{\tau_j - \epsilon}^{\tau_j + \epsilon} \|A^\alpha(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)\| ds
\]
\[
+ \int_{\tau_j - \epsilon}^{\tau_j - \epsilon} \|A^\alpha(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)\| ds
\]
\[
+ \sum_{k=1}^{\infty} \int_{\tau_{k-1}}^{\tau_k} \|A^\alpha(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)\| ds. \quad (44)
\]

Let us consider all integrals in \((44)\) separately. By \((36)\) and \((13)\) we have

\[
I_{11} = \int_{\tau_j + \epsilon}^{t} \|A^\alpha(V_2(t, s)(I - P_2(s)) - V(t, s)(I - P(s)))f(s + r)\| ds
\]
\[
= \int_{\tau_j + \epsilon}^{t} \|A^\alpha((I - P_2(t))V_2(t, s) - (I - P(t))V(t, s))f(s + r)\| ds
\]
\[
\leq \int_{\tau_j + \epsilon}^{t} \|A^\alpha(P_2(t) - P(t))V_2(t, s)f(s + r)\| ds
\]
\[
+ \int_{\tau_j + \epsilon}^{t} \|A^\alpha(I - P(t))(V_2(t, s) - V(t, s))f(s + r)\| ds
\]
\[
\leq \left( \int_{\tau_j + \epsilon}^{t} \frac{M_4(\epsilon)\alpha ds}{(t - s)^{2\alpha - 1}} + \int_{\tau_j + \epsilon}^{t} \frac{R_3(\epsilon)ds}{(t - s)^{2\alpha - 1}} \right) \|f\|_{PC} \leq \Gamma_1(\epsilon)\|f\|_{PC}.
\]
Analogously, we have

\[ I_{12} = \int_{\tau_i - \varepsilon}^{\tau_i + \varepsilon} ||A^\alpha U(t, s)(I - P(s))f(s + h)|| ds \]

\[ \leq \int_{\tau_i}^{\tau_i + \varepsilon} ||A^\alpha(I - P(t))V(t, s)f(s + h)|| ds \]

\[ + \int_{\tau_i - \varepsilon}^{\tau_i} ||A^\alpha(I - P(t))V(t, \tau_i)(I + B_i)U(\tau_i, s)f(s + h)|| ds \]

\[ \leq \left( \int_{\tau_i}^{\tau_i + \varepsilon} \frac{C_\alpha ds}{(t-s)^{\alpha}} M ||I + B_i|| \int_{\tau_i - \varepsilon}^{\tau_i} \frac{C_\alpha ds}{(s-\tau_i)^{\alpha}} ||f||_{PC} \right) \leq \Gamma_2(\varepsilon) ||f||_{PC}. \]

Similarly, we get

\[ I_{13} = \int_{\tau_i - \varepsilon}^{\tau_i + \varepsilon} ||A^\alpha U_2(t, s)(I - P_2(s))f(s + h)|| ds \leq \Gamma_3(\varepsilon) ||f||_{PC}, \]

where \( \Gamma_j(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \), \( j = 1, 2, 3 \).

Using (13) and (36), we get

\[ I_{14} = \int_{\eta_i}^{\tau_i - \varepsilon} ||A^\alpha(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)|| ds \]

\[ = \int_{\eta_i}^{\tau_i - \varepsilon} \left\| \left( (I - P_2(t))V_2(t, \tau_i)(I + B_i)V_1(\tau_i, s) - (I - P(t))V(t, \tau_i)(I + B_i)V_2(\tau_i, s) \right) f(s + h) \right\|_{ad} ds \]

\[ \leq \int_{\eta_i}^{\tau_i - \varepsilon} \left\| (P_2(t) - P(t))V_2(t, \tau_i)(I + B_i)V_2(\tau_i, s) f(s + h) \right\|_{ad} ds \]

\[ + \int_{\eta_i}^{\tau_i - \varepsilon} \left\| (I - P(t))(V_2(t, \tau_i) - V(t, \tau_i))(I + B_i)V_2(\tau_i, s) f(s + h) \right\|_{ad} ds \]

\[ + \int_{\eta_i}^{\tau_i - \varepsilon} \left\| (I - P(t))V(t, \tau_i)(B_i - B_i)V_2(\tau_i, s) f(s + h) \right\|_{ad} ds \]

\[ + \int_{\eta_i}^{\tau_i - \varepsilon} \left\| (I - P(t))(V(t, \tau_i) - V(\tau_i))(I - B_i)V_2(\tau_i, s) - V(\tau_i, s) f(s + h) \right\|_{ad} ds \]

\[ \leq \Gamma_4(\varepsilon) ||f||_{PC}. \]

where \( \Gamma_4(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

The last sum in (44) is transformed as follows:

\[ I_{15} = \sum_{k=1}^{\infty} \int_{\eta_i - k}^{\eta_i - k + 1} ||A^\alpha(U_2(t, s)(I - P_2(s)) - U(t, s)(I - P(s)))f(s + r)|| ds \]

\[ = \sum_{k=1}^{\infty} \int_{\eta_i - k}^{\eta_i - k + 1} \left\| (U(t, \eta_i - k))(I - P(\eta_i - k + 1))U(\eta_i - k + 1, s) - U_2(t, \eta_i - k + 1)U_2(\eta_i - k + 1, s) f(s + h) \right\|_{ad} ds \]
and Green's functions with corresponding evolution operators

\[ G_n = \sum_{k=1}^{\infty} \int_{\eta_{n-k}}^{\eta_n} \left\| \left( U(t, \eta_i) - U_2(t, \eta_i) \right) (I - P(\eta_i)) U(\eta_i, \eta_{i+k}) U(\eta_{i+k-1}, s) + U_2(t, \eta_i) (I - P(\eta_i)) U(\eta_i, \eta_{i+k}) - (I - P_2(\eta_i)) U_2(\eta_i, \eta_{i+k}) U(\eta_{i+k-1}, s) + U_2(t, \eta_i) (I - P_2(\eta_i)) (U(\eta_{i+k-1}, s) - U_2(\eta_{i+k-1}, s)) \right\| \, ds. \]

As in the proof of Lemma 5, we construct in space \( X^\alpha \) two sequences of bounded operators

\[ S_n = U(\eta_{n+1}, \eta_n), \quad \tilde{S}_n = U_2(\eta_{n+1}, \eta_n), \quad n \in \mathbb{Z}, \]

and corresponding difference equations

\[ u_{n+1} = S_n u_n, \quad v_{n+1} = \tilde{S}_n v_n, \quad n \in \mathbb{Z}. \]

Per our assumption, these difference equations are exponentially dichotomous with corresponding evolution operators

\[ S_{n,m} = S_{n-1} \cdots S_m, \quad \tilde{S}_{n,m} = \tilde{S}_{n-1} \cdots \tilde{S}_m, \quad n \geq m, \]

and Green's functions

\[ G_{n,m} = \begin{cases} S_{n,m}(I - P_m), & n \geq m, \\ -S_{n,m} P_m, & n < m, \end{cases} \quad \tilde{G}_{n,m} = \begin{cases} \tilde{S}_{n,m}(I - \tilde{P}_m), & n \geq m, \\ -\tilde{S}_{n,m} \tilde{P}_m, & n < m, \end{cases} \]

where \( P_m = P(\eta_m), \tilde{P}_m = P_2(\eta_m) \).

Analogous to (32) and (33), we obtain

\[ \tilde{G}_{n,m} - G_{n,m} = \sum_{k=1}^{n-m} G_{n,k+1}(\tilde{S}_k - S_k) G_{k,m} \]

and

\[ \| \tilde{G}_{n,m} - G_{n,m} \|_\alpha = M_1 e^{-\beta_1 |n-m|} \sup_k \| \tilde{S}_k - S_k \|_\alpha, \quad n, m \in \mathbb{Z} \quad (45) \]

with some constants \( \beta_1 \leq \beta, M_1 \geq M \).

\[ \| S_n - \tilde{S}_n \|_\alpha = \| U(\eta_{n+1}, \eta_n) - U_2(\eta_{n+1}, \eta_n) \|_\alpha \]

\[ = \| V(\eta_{n+1}, \tau_n)(I + B_n) V(\tau_n, \eta_n) - V_2(\eta_{n+1}, \tilde{\tau}_n)(I + \tilde{B}_n) V_2(\tilde{\tau}_n, \eta_n) \|_\alpha \]

\[ \leq \| V(\eta_{n+1}, \tau_n) - V_2(\eta_{n+1}, \tilde{\tau}_n) \|_\alpha \| (I + B_n) V(\tau_n, \eta_n) \|_\alpha \]

\[ + \| V_2(\eta_{n+1}, \tilde{\tau}_n)(I + \tilde{B}_n) V(\tau_n, \eta_n) \|_\alpha \]

\[ + \| V_2(\eta_{n+1}, \tilde{\tau}_n)(I + \tilde{B}_n)(V(\tau_n, \eta_n) - V_2(\tilde{\tau}_n, \eta_n)) \|_\alpha. \]

Here we assume for definiteness that \( \tilde{\tau}_n \geq \tau_n \). We have

\[ \| V(\eta_{n+1}, \tau_n) - V_2(\eta_{n+1}, \tilde{\tau}_n) \|_\alpha \leq \| V(\eta_{n+1}, \tilde{\tau}_n) V(\tilde{\tau}_n, \tau_n) - I \|_\alpha \]

\[ + \| V(\eta_{n+1}, \tilde{\tau}_n) - V_2(\eta_{n+1}, \tilde{\tau}_n) \|_\alpha. \]
\[ \leq \Gamma_3(\varepsilon) \| y \|_\alpha \]

and

\[
\| (V_2(\tau_n, \eta_n) - V(\tau_n, \eta_n))y \|_\alpha \leq \| (V_2(\tau_n, \tau_n) - I)V_2(\tau_n, \eta_n)y \|_\alpha \\
+ \| V_2(\tau_n, \eta_n) - V(\tau_n, \eta_n)y \|_\alpha \leq \Gamma_6(\varepsilon) \| y \|_\alpha
\]

where \( \Gamma_3(\varepsilon) \to 0 \) and \( \Gamma_6(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

Now we get

\[
\| S_n - S_n \|_\alpha \leq \Gamma_3(\varepsilon) \| I + B_n \| \| U(\tau_n, \eta_n) \|_\alpha \\
+ \varepsilon \| U_2(\eta_n, \tau_n) \|_\alpha \| U(\tau_n, \eta_n) \|_\alpha + \Gamma_6(\varepsilon) \| U_2(\eta_{n+1}, \tilde{\eta}) \|_\alpha \| I + \tilde{B}_n \| \leq \Gamma_7(\varepsilon)
\]

by (45)

\[
\| U(\eta_n, \eta_{i-k}) - U_2(\eta_i, \eta_{i-k}) \|_\alpha \leq M_1 \varepsilon^{-\beta_i \delta_k} \Gamma_7(\varepsilon),
\]

where \( \Gamma_7(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

Continuing to evaluate \( I_{15} \), we can obtain the inequalities

\[
\| U_2(t, \eta_i)g \|_\alpha \leq M_2 \| g \|_\alpha, \\
\| (U(t, \eta_i) - U_2(t, \eta_i))g \|_\alpha \leq \Gamma_3(\varepsilon) \| g \|_\alpha, \\
\int_{\eta_{i-k+1}}^{\eta_{i-k+1}} \| (U(\eta_{i-k+1}, s) - U_2(\eta_{i-k+1}, s))f(s+h) \|_\alpha ds \leq \Gamma_6(\varepsilon) \| f \|_{PC},
\]

where \( \Gamma_3(\varepsilon) \to 0 \) and \( \Gamma_6(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \), \( M_2 \) is some positive constant. Note that as earlier, \( t \in (\tau_i + \varepsilon, \tau_{i+1} - \varepsilon) \).

Taking into account the last inequalities, we conclude that series \( I_{15} \) is convergent and there exists \( \Gamma_{10}(\varepsilon) \) such that \( I_{15} \leq \Gamma_{10}(\varepsilon) \| f \|_{PC} \) and \( \Gamma_{10}(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

Using estimations for \( I_{11}, ..., I_{15} \), we get that there exists \( \Gamma_{11}(\varepsilon) \) such that

\[
\int_0^\infty \| (G(t + r, s + r) - G(t, s))f(s + r) \|_\alpha ds \leq \Gamma_{11}(\varepsilon) \| f \|_{PC}
\]

and \( \Gamma_{11}(\varepsilon) \to 0 \) as \( \varepsilon \to 0 \).

By Lemma [1] \( |\tau_{i+q} - \tau_j - h| < \varepsilon \); therefore, \( \tau_j + h + \varepsilon > \tau_{i+q} \) (we assume that \( h > 0 \) for definiteness). The difference \( G(t, \tau_j + 0) - G(t + h, \tau_{i+q} + 0) \) is estimated as follows. Let \( t - \tau_j \geq \varepsilon \). Then

\[
\| (G(t, \tau_j + 0) - G(t + h, \tau_{i+q} + 0))g_{j+q} \|_\alpha \\
= \| (U(t, \tau_j + 0)(I - P(\tau_j + 0)) - U(t + h, \tau_{i+q} + 0)(I - P(\tau_{i+q} + 0)))g_{j+q} \|_\alpha \\
\leq \| (U(t, \tau_j + 0)(I - P(\tau_j + 0)) - U(t, \tau_j + \varepsilon)(I - P(\tau_j + \varepsilon)))g_{j+q} \|_\alpha \\
+ \| (U(t, \tau_j + \varepsilon)(I - P(\tau_j + \varepsilon)) - U(t + h, \tau_j + \varepsilon + h) \\
\times (I - P(\tau_j + \varepsilon + h)))g_{j+q} \|_\alpha + \| (U(t + h, \tau_{i+q} + 0)(I - P(\tau_{i+q} + 0)) \\
- U(t + h, \tau_j + \varepsilon + h)(I - P(\tau_j + \varepsilon + h)))g_{j+q} \|_\alpha.
\]
The first and third differences are small due to the continuity of function $U(t,s)$ at intervals between impulse points:

$$\begin{align*}
&\|U(t,\tau_j+0)(I-P(\tau_j+0))-U(t,\tau_j+\epsilon)(I-P(\tau_j+\epsilon))g_{j+q}\|_\alpha \\
&\leq \|U(t,\tau_j+\epsilon)(I-P(\tau_j+\epsilon))(U(\tau_j+\epsilon,\tau_j+0)-I)g_{j+q}\|_\alpha \\
&\leq \|U(t,\tau_j+\epsilon)(I-P(t))(U(\tau_j+\epsilon,\tau_j+0)-I)g_{j+q}\|_\alpha \\
&\leq Me^{-\beta(t-\tau_j-\epsilon)}\frac{1}{\alpha_1-\alpha}C_1\epsilon^{\alpha_1-\alpha}\|g_{j+q}\|_\alpha,
\end{align*}$$

$$\begin{align*}
&\|U(t+h,\tau_j+\epsilon+h)(I-P(\tau_j+\epsilon+h))
-U(t+h,\tau_j+\epsilon+h)(I-P(\tau_j+\epsilon+h))g_{j+q}\|_\alpha \\
&= \|U(t,\eta_j)(I-P(\eta_j))U(\eta_j,\eta_{j+1})U(\tau_j+\epsilon) \\
&\quad -U_2(t,\eta_j)(I-P(\eta_j))U_2(\eta_j,\eta_{j+1})U_2(\tau_j+\epsilon)||\alpha \\
&\leq \|U(t,\eta_j)-U_2(t,\eta_j)(I-P(\eta_j))U(\eta_j,\eta_{j+1})U(\tau_j+\epsilon)||\alpha \\
&+\|U_1(t,\eta_j)(P(\eta_j))U(\eta_j,\eta_{j+1})-P_2(\eta_j)U_2(\eta_j,\eta_{j+1})U(\tau_j+\epsilon)||\alpha \\
&\quad +\|U_2(t,\eta_j)P_2(\eta_j)U_2(\eta_j,\eta_{j+1})U(\tau_j+\epsilon)-U_2(\eta_j,\tau_j+\epsilon)||\alpha. \\
\end{align*}$$

The second difference in (48) is estimated using inequality (46) and the following transformation:

$$\begin{align*}
&\|U(t,\tau_j+\epsilon)(I-P(\tau_j+\epsilon))-U(t+h,\tau_j+\epsilon+h)(I-P(\tau_j+\epsilon+h))\|_\alpha \\
&= \|U(t,\eta_j)(I-P(\eta_j))U(\eta_j,\eta_{j+1})U(\tau_j+\epsilon) \\
&+U_2(t,\eta_j)(I-P(\eta_j))U_2(\eta_j,\eta_{j+1})U_2(\tau_j+\epsilon)||\alpha \\
&\leq \|U(t,\eta_j)-U_2(t,\eta_j)(I-P(\eta_j))U(\eta_j,\eta_{j+1})||\alpha \\
&+\|U_1(t,\eta_j)(P(\eta_j))U(\eta_j,\eta_{j+1})-P_2(\eta_j)U_2(\eta_j,\eta_{j+1})||\alpha \\
&\quad +\|U_2(t,\eta_j)P_2(\eta_j)U_2(\eta_j,\eta_{j+1})||\alpha. \\
\end{align*}$$

Therefore,

$$\sum_{j\in\mathbb{Z}}\|G(t+h,\tau_{j+q}+0)-G(t,\tau_j+0)\|_\alpha \leq \Gamma_1(\epsilon)||g_{j+q}\|_\alpha, \quad (49)$$

where $\Gamma_1(\epsilon)\to 0$ as $\epsilon\to 0$.

The second integral and first sum in (40) are estimated as in (39):

$$\int_{-\infty}^{\infty}\|G(t,s))(f(s+h)-f(s))\|_\alpha ds + \sum_{j\in\mathbb{Z}}\|U(t,\tau_j+0)(g_{j+q}-g_j)\|_\alpha \leq M_3\epsilon$$

since $h$ is $\epsilon$-almost period of the right-hand side of the equation.

As a result of these evaluations, we get

$$\|u_0(t+h)-u_0(t)\|_\alpha \leq \Gamma(\epsilon) \quad \text{for} \quad t\in\mathbb{R}, \quad |t-\tau_j|>\epsilon, \quad j\in\mathbb{Z},$$

with $\Gamma(\epsilon)\to 0$ as $\epsilon\to 0$. The last inequality implies that the function $u_0(t)$ is $\mathcal{W}$-almost periodic as function $R\to X^\alpha$. 
Corollary 2. Assume that Eq. (50), (51) satisfies the following:

i) conditions (H1) – (H3), (H7);
ii) the sequence \( \{g_j\} \) of \( g_j \in X^\alpha \) is almost periodic;
iii) the corresponding homogeneous equation is exponentially dichotomous.

Then the equation has a unique W-almost periodic solution \( u_0(t) \in \mathcal{P} \mathcal{C}(\mathbb{R},X^\gamma) \) with \( \gamma < \alpha \).

Now we consider a nonlinear equation with fixed moments of impulsive action:

\[
\begin{align*}
\frac{du}{dt} + (A + A_1(t))u &= f(t,u), \quad t \neq \tau_j, \\
\Delta u|_{t=\tau_j} &= u(\tau_j + 0) - u(\tau_j) = B_j u(\tau_j) + g_j(u(\tau_j)), \quad j \in \mathbb{Z},
\end{align*}
\]

Theorem 2. Let us consider Eq. (50), (51) in some domain \( U_\rho^\alpha = \{ x \in X^\alpha : \|x\|_\alpha \leq \rho \} \) of space \( X^\alpha \). Assume that

1) the equation satisfies assumptions (H1) – (H4), \( \tau_j = \tau_j(0) \);
2) the corresponding linear equation is exponentially dichotomous on constants \( \beta > 0 \) and \( M \geq 1 \);
3) the function \( f(t,u) : \mathbb{R} \times U_\rho^\alpha \rightarrow X \) is continuous in \( u \), W-almost periodic and
   locally Hölder continuous in \( t \) uniformly with respect to \( u \in U_\rho^\alpha \) and there exist constants \( N_1 > 0 \) and \( \nu > 0 \) such that
   \[
   \|f(t_1,u_1) - f(t_2,u_2)\| \leq N_1 (|t_1 - t_2|^\nu + \|u_1 - u_2\|_\alpha)
   \]
   if \( u_1, u_2 \in U_\rho^\alpha \), and points \( t_1 \) and \( t_2 \) belong to the same interval of continuity;
4) the sequence \( \{g_j(u)\} \) of continuous functions \( U_\rho^\alpha \rightarrow X^{\alpha_1} \) is almost periodic uniformly with respect to \( u \in U_\rho^\alpha \) and
   \[
   \|g_j(u_1) - g_j(u_2)\|_{\alpha_1} \leq N_1 \|u_1 - u_2\|_{\alpha_1}, \quad j \in \mathbb{Z}.
   \]
   Also \( \|g_j(u_1) - g_j(u_2)\|_{\alpha_1} \leq N_1 \|u_1 - u_2\|_{\alpha_1} \) for \( j \in \mathbb{Z} \) and \( u \in U_\rho^\alpha \cap X^{\alpha_1} \) with some \( \alpha_1 > \alpha \);
5) the functions \( \|f(t,0)\|_{\alpha} \) and \( \|g_j(0)\|_{\alpha_1} \) are uniformly bounded for \( t \in \mathbb{R}, j \in \mathbb{Z} \);
6) \( N_1 M_\rho < 1 \) and \( \rho \geq M_\rho M_*/(1 - N_1 M_\rho) \), where
   \[
   M_* = \frac{M_1}{1 - e^{-\beta_1/\alpha}} \left( 1 + \frac{C_\alpha G^{1-\alpha}}{1 - \alpha} \right)
   \]
   and constants \( \beta_1 \) and \( M_1 \) are defined by Lemma 5.

Then in domain \( U_\rho^\alpha \) for sufficiently small \( N_1 > 0 \) there exists a unique W-almost periodic solution \( u_0(t) \) of Eq. (50), (51).

Proof. Denote by \( \mathcal{M}_\rho \) the set of all W-almost periodic functions \( \varphi : \mathbb{R} \rightarrow X^\alpha \) with discontinuity points \( \tau_j, j \in \mathbb{Z} \), satisfying the inequality \( \|\varphi\|_{\mathcal{P} \mathcal{C}} \leq \rho \). In \( \mathcal{M}_\rho \), we define the operator

\[
(\mathcal{F} \varphi)[t] = \int_{-\infty}^{\infty} G(t,s)f(s,\varphi(s))ds + \sum_{j \in \mathbb{Z}} G(t,\tau_j + 0)g_j(\varphi(\tau_j)).
\]
Proceeding in the same way as in the proof of Theorem 11, we prove that \((\mathcal{F} \varphi)(t)\) is a W-almost periodic function and \(\mathcal{F} : \mathcal{M}_\rho \to \mathcal{M}_\rho\) for \(\rho > 0\) satisfying Condition 6.

Next, \(\mathcal{F}\) is a contracting operator in \(\mathcal{M}_\rho\) by sufficiently small \(N_1 > 0\).

Hence, there exists \(\varphi_0 \in \mathcal{M}_\rho\) such that
\[
\varphi_0(t) = \int_{-\infty}^{\infty} G(t, s)f(s, \varphi_0(s))ds + \sum_{j \in \mathbb{Z}} G(t, \tau_j + 0)g_j(\varphi_0(\tau_j)).
\]

The function \(\varphi_0(t)\) is locally Hölder continuous on every interval \((\tau_j, \tau_{j+1}), j \in \mathbb{Z}\). Actually,
\[
\varphi_0(t + \delta) - \varphi_0(t) = \int_{-\infty}^{\infty} G(t + \delta, s)f(s, \varphi_0(s))ds - \int_{-\infty}^{\infty} G(t, s)f(s, \varphi_0(s))ds
+ \sum_{j \in \mathbb{Z}} G(t + \delta, \tau_j + 0)g_j(\varphi_0(\tau_j)) - \sum_{j \in \mathbb{Z}} G(t, \tau_j + 0)g_j(\varphi_0(\tau_j))
= \int_{-\infty}^{\infty} (V(t + \delta, t) - I)U(t, s)(I - P(s))f(s, \varphi_0(s))ds
- \int_{t+\delta}^{\infty} (V(t + \delta, t) - I)U(t, s)P(s)f(s, \varphi_0(s))ds
+ \sum_{\tau_j \leq t} (V(t + \delta, t) - I)U(t, \tau_j)P(\tau_j + 0)g_j(\varphi_0(\tau_j))
+ \sum_{\tau_j > t} (V(t + \delta, t) - I)U(t, \tau_j + 0)P(\tau_j + 0)g_j(\varphi_0(\tau_j)).
\]

Applying (11), (20), (21), and (39), we conclude that for every interval \(t \in (t', t'')\) not containing impulse points \(\tau_j\), there exists positive constant \(C\) such that
\[
\|\varphi_0(t + \delta) - \varphi_0(t)\|_{\alpha} \leq C\delta^\alpha - \alpha.
\]

The local Hölder continuity of \(f(t, \varphi_0(t))\) follows from
\[
\|f(t, \varphi_0(t)) - f(s, \varphi_0(s))\| \leq N_1 (|t - s|^\nu + \|\varphi_0(t) - \varphi_0(s)\|_{\alpha})
\leq C_1 (|t - s|^\nu + |t - s|^{\alpha - \alpha}) .
\]

By Lemma 37, (13), p. 214, if \(\varphi_0(t)\) is W-almost periodic and \(\inf_k (\tau_{k+1} - \tau_k) > 0\), then \(\{\varphi_0(\tau_k)\}\) is an almost periodic sequence.

The linear inhomogeneous equation
\[
\frac{du}{dt} + (A + A_1(t))u = f(t, \varphi_0(t)), \quad t \neq \tau_j, \tag{52}
\]
\[
\Delta u|_{t=\tau_j} = u(\tau_j + 0) - u(\tau_j) = B_ju(\tau_j) + g_j(\varphi_0(\tau_j)), \quad j \in \mathbb{Z}, \tag{53}
\]
has a unique W-almost periodic solution in the sense of Definition 4. Due to the uniqueness, it coincides with \(\varphi_0(t)\).
Hence, the W-almost periodic function \( q_0(t) : R \rightarrow X^\alpha \) satisfies Eq. (50) for \( t \in (\tau_j, \tau_{j+1}) \) and difference equation (51) for \( t = \tau_j \).

Now we study the stability of the almost periodic solution assuming exponential stability of the linear equation. First, using ideas in [17], we prove following generalized Gronwall inequality for impulsive systems.

**Lemma 6.** Assume that \( \{t_j\} \) is an increasing sequence of real numbers such that \( Q \geq t_{j+1} - t_j \geq \theta > 0 \) for all \( j, M_1, M_2, \) and \( M_3 \) are positive constants, and \( \alpha \in (0, 1) \). Then there exists a positive constant \( \tilde{C} \) such that positive piecewise continuous function \( u : [0, t) \rightarrow R \) satisfying

\[
\begin{align*}
    z(t) &\leq M_1 z_0 + M_2 \sum_{j=1}^{m} \int_{t_{j-1}}^{t_{j}} (t_j - s)^{-\alpha} z(s) ds + \int_{t_{m}}^{t} (t - s)^{-\alpha} z(s) ds + M_3 \sum_{j=1}^{m} z(t_j) \\
    &\quad + M_3 \sum_{j=1}^{m} z(t_j) \quad \text{for} \quad t \in (t_m, t_{m+1}] 
\end{align*}
\]

also satisfies

\[
    z(t) \leq M_1 z_0 \tilde{C} \left( 1 + M_2 \tilde{C} \frac{Q^{1-\alpha}}{1 - \alpha} + M_3 \tilde{C} \right)^m. \tag{55}
\]

**Proof.** We apply the method of mathematical induction. At the interval \( t \in [0, t_1] \) the inequality (54) has the form

\[
    z(t) \leq M_1 z_0 + M_2 \int_{0}^{t_1} (t_1 - s)^{-\alpha} z(s) ds.
\]

By Lemma 3 there exists \( \tilde{C} \) such that

\[
    0 \leq z(t) \leq M_1 z_0 \tilde{C}, \quad t \in [0, t_1], \quad \tilde{C} = \tilde{C}(M_1, M_2, Q).
\]

Hence, (55) is true for \( t \in [0, t_1] \). Assume (55) is true for \( t \in [0, t_n] \) and prove it for \( t \in (t_n, t_{n+1}] \). Hence, for \( t \in (t_n, t_{n+1}] \) we have

\[
\begin{align*}
    z(t) &\leq M_1 z_0 + M_2 \int_{t_n}^{t_1} (t_1 - s)^{-\alpha} z(s) ds + M_3 \sum_{j=1}^{n} z(t_j) + M_2 \int_{t_n}^{t} (t - s)^{-\alpha} z(s) ds \\
    &\quad + M_3 \sum_{j=2}^{n} z(t_j) \\
    &\leq M_1 z_0 + M_2 \frac{Q^{1-\alpha}}{1 - \alpha} M_1 z_0 \tilde{C} + M_3 M_1 z_0 \tilde{C} + M_2 \int_{t_n}^{t} (t - s)^{-\alpha} z(s) ds \\
    &\quad + \sum_{j=2}^{n} \left( 1 + M_2 \tilde{C} \frac{Q^{1-\alpha}}{1 - \alpha} + M_3 \tilde{C} \right) \left( M_2 \tilde{C} \frac{Q^{1-\alpha}}{1 - \alpha} + M_3 \tilde{C} \right)^{j-1} M_1 z_0 \\
    &\quad = M_1 z_0 + M_2 \frac{Q^{1-\alpha}}{1 - \alpha} M_1 z_0 \tilde{C} + M_3 M_1 z_0 \tilde{C} + M_2 \int_{t_n}^{t} (t - s)^{-\alpha} z(s) ds
\end{align*}
\]
sponding linear equation be exponentially stable.

Theorem 3. Let Eq. (50), (51) satisfy assumptions of Theorem 2 and let the corresponding linear equation be exponentially stable.

Then for sufficiently small $N_1 > 0$, the equation has a unique W-almost periodic solution $u_0(t)$, and this solution is exponentially stable.

Proof. The existence and uniqueness of the W-almost periodic solution $u_0(t)$ follows from Theorem 2. We prove its asymptotic stability. Let $u(t)$ be an arbitrary solution of the equation satisfying $\|u(t_0) - u_0(t_0)\|_\alpha \leq \delta$, where $\delta$ is small positive number.

Then by $t \geq t_0$ the difference of these solutions satisfies

$$
u(t) - u_0(t) = U(t, t_0)(u(t_0) - u_0(t_0)) + \int_{t_0}^{t} U(t, s) \left( f(s, u(s)) - f(s, u_0(s)) \right) ds + \sum_{t_0 \leq \tau_k \leq t} U(t, \tau_k + 0) \left( g_k(u(\tau_k)) - g_k(u_0(\tau_k)) \right).$$

Then for $t_0 \in (\tau_0, \tau_1)$ and $t \in (\tau_j, \tau_{j+1}]$ we have

$$
\|\nu(t) - u_0(t)\|_\alpha \leq \|U(t, t_0)(u(t_0) - u_0(t_0))\|_\alpha + \int_{t_0}^{t_1} \|U(t, \tau_k + 0)\|_\alpha \|V(\tau_k, s)(f(s, u(s)) - f(s, u_0(s)))\|_\alpha ds + \ldots
+ \int_{t_0}^{t_{j+1}} \|U(t, \tau_k + 0)\|_\alpha \|V(\tau_k, s)(f(s, u(s)) - f(s, u_0(s)))\|_\alpha ds + \ldots
+ \sum_{t_0 \leq \tau_k \leq t} \|U(t, \tau_k + 0)\|_\alpha \|g_k(u(\tau_k)) - g_k(u_0(\tau_k))\|_\alpha
\leq Me^{-\beta(t-t_0)} \|u(t_0) - u_0(t_0)\|_\alpha + Me^{-\beta(t-\tau_1)} \int_{t_0}^{\tau_1} \frac{L_0N_1}{(\tau_1 - s)^\alpha} \|u(s) - u_0(s)\|_\alpha ds + \ldots + Me^{-\beta(t-\tau_j)} \int_{\tau_{j-1}}^{\tau_j} \frac{L_0N_1}{(\tau_j - s)^\alpha} \|u(s) - u_0(s)\|_\alpha ds
$$
Almost periodic evolution equations

\[ + \int_{\tau_j}^{t} L_{0}N_{1} |u(s) - u_{0}(s)|_{\alpha} ds + \sum_{t_{0} \leq \tau_{k} \leq t} M e^{-\beta(t - \tau_{k})} N_{1} |u(\tau_{k}) - u_{0}(\tau_{k})|_{\alpha} \]

Denote \( v(t) = e^{\beta t} \|u(t) - u_{0}(t)\|_{\alpha} \), \( M_{2} = e^{\beta M L_{0} N_{1}} \), \( M_{3} = MN_{1} \). Then

\[ v(t) \leq M v(t_{0}) + M_{2} \int_{t_{0}}^{t_{1}} \frac{v(s)ds}{(\tau_{1} - s)^{\alpha}} + \ldots + M_{2} \int_{t_{j}}^{t} \frac{v(s)ds}{(\tau_{j} - s)^{\alpha}} + M_{3} \sum_{i=1}^{j} v(\tau_{k}). \]

Then by Lemma 6 we get

\[ \|u(t) - u_{0}(t)\|_{\alpha} \leq M \tilde{C} e^{-\beta(t - t_{0})} \left( 1 + M_{2} \tilde{C} \frac{Q^{1 - \alpha}}{1 - \alpha} + M_{3} \tilde{C} \right)^{j(t - t_{0})} \|u(t_{0}) - u_{0}(t_{0})\|_{\alpha} \]

Therefore, if

\[ \beta > p \ln \left( 1 + M_{2} \tilde{C} \frac{Q^{1 - \alpha}}{1 - \alpha} + M_{3} \tilde{C} \right), \]

where \( p \) is defined by (3), then W-almost periodic solution \( u_{0}(t) \) of Eq. (50), (51) is asymptotically stable. This can be achieved by sufficiently small \( N_{1} \).

5 Almost Periodic Solutions of Equations with Nonfixed Moments of Impulsive Action

We consider the following equation with points of impulsive action depending on solution

\[ \frac{du}{dt} + Au = f(t, u), \quad t \neq \tau_{j}(u), \quad (57) \]

\[ u(\tau_{j}(u) + 0) - u(\tau_{j}(u)) = B_{j} u + g_{j}(u), \quad j \in Z. \quad (58) \]

**Definition 6.** (11). A solution \( u_{0}(t) \) of Eq. (57), (58) defined for all \( t \geq t_{0} \), is called Lyapunov stable in space \( X^{\alpha} \) if, for an arbitrary \( \varepsilon > 0 \) and \( \eta > 0 \), there exists such a number \( \delta = \delta(\varepsilon, \eta) \) that, for any other solution \( u(t) \) of system, \( \|u_{0}(t_{0}) - u(t_{0})\|_{\alpha} < \delta \) implies that \( \|u_{0}(t) - u(t)\|_{\alpha} < \varepsilon \) for all \( t \geq t_{0} \) such that \( |t - \tau_{0}^{0}| > \eta \), where \( \tau_{0}^{0} \) are the times at which the solution \( u_{0}(t) \) intersects the surfaces \( t = \tau_{j}(u), j \in Z \).

A solution \( u_{0}(t) \) is said to be attractive, if for each \( \varepsilon > 0, \eta > 0, \) and \( t_{0} \in R \), there exist \( \delta_{0} = \delta_{0}(t_{0}) \) and \( T = T(\delta_{0}, \varepsilon, \eta) > 0 \) such that for any other solution \( u(t) \) of the system, \( \|u_{0}(t_{0}) - u(t)\|_{\alpha} < \delta \) implies \( \|u_{0}(t) - u(t)\|_{\alpha} < \varepsilon \) for \( t \geq t_{0} + T \) and \( |t - \tau_{k}^{0}| > \eta \).

A solution \( u_{0}(t) \) is called asymptotically stable if it is stable and attractive.

**Theorem 4.** Assume that in domain \( U_{\rho}^{\alpha} = \{ u \in X^{\alpha}, \|u\|_{\alpha} \leq \rho \} \), Eq. (57), (58) satisfies conditions (H1), (H3) – (H6), and
1) all solutions in domain $U^a$ intersect each surface $t = \tau_j(u)$ no more then once;
2) $\|f(t_1, u) - f(t_2, u)\| \leq H_1|t_1 - t_2|$, $H_1 > 0$;
3) $\|f(t, u_1) - f(t, u_2)\| + \|g_j(u_1) - g_j(u_2)\|_\alpha + |\tau_j(u_1) - \tau_j(u_2)| \leq N_1||u_1 - u_2||_\alpha$, uniformly in $t \in R, u \in U^a$, $j \in Z$.
4) $AB_j = B_jA$ and $\|f(t, 0)\| \leq M_0, \|g_j(0)\|_1 \leq M_0$ for all $j \in Z$;
5) the linear homogeneous equation

$$\frac{du}{dt} + Au = 0, \quad t \neq \tau_j,$$  
$$\Delta u|_{t=\tau_j} = u(\tau_j + 0) - u(\tau_j) = B_ju(\tau_j), \quad j \in Z,$$

is exponentially stable in space $X^a$

$$\|U(t, s)u\|_\alpha \leq Me^{-\beta(t-s)}\|u\|_\alpha, \quad t \geq s, u \in X^a,$$

where $\tau_j = \tau_j(0), \beta > 0$ and $M \geq 1$;

6) $N_1M_s < 1$ and $\rho \geq M_0M_s/(1 - N_1M_s)$, where

$$M_s = \frac{M_1}{1 - e^{-\beta_1\theta}} \left(1 + \frac{C\rho^{1-\alpha}}{1 - \alpha}\right),$$

where constants $\beta_1$ and $M_1$ are defined by Lemma 9.

Then for sufficiently small values of Lipschitz constant $N_1$, Eq. (57), (58) has in $U^a$ a unique W-almost periodic solution and this solution is exponentially stable.

**Proof.** 1. First, using the method proposed in [6], we proof the existence of the W-almost periodic solution. Let $y = \{y_j\}$ be an almost periodic sequence of elements $y \in X^a, \|y\|_\alpha \leq \rho$. We consider the equation with fixed moments of impulsive action

$$\frac{du}{dt} + Au = f(t, u), \quad t \neq \tau_j(y),$$  
$$u(\tau_j(y_j) + 0) - u(\tau_j(y_j)) = B_ju(\tau_j(y_j)) + g_j(y_j), \quad j \in Z.$$

By Lemma 9 if a constant $N_1$ sufficiently small, then corresponding to (61) and (62), the linear impulsive equation (if $f \equiv 0, g_j(y_j) \equiv 0, j \in Z$) is exponentially stable. Its evolution operator $U(t, \tau, y)$ satisfies estimate

$$\|U(t, \tau, y)u\|_\alpha \leq M_1e^{-\beta_1(t-\tau)}\|u\|_\alpha, \quad t \geq \tau,$$

with some positive constants $M_1 \geq M, \beta_1 \leq \beta$.

The equation (61), (62) has a unique solution bounded on the axis which satisfies the integral equation

$$u(t, y) = \int_{-\infty}^{t} U(t, \tau, y)f(\tau, u(\tau, y))d\tau + \sum_{\tau_j(y_j) \leq t} U(t, \tau_j(y_j) + 0, y)g_j(y_j).$$
Almost periodic evolution equations

We choose \( u_0(t,y) \equiv 0 \) and construct the sequence of W-almost periodic functions \( u_{n+1}(t,y) = \)

\[
= \int_{-\infty}^{t} U(t, \tau, y)f(\tau, u_n(\tau,y))d\tau + \sum_{\tau_j(y_j) \leq t} U(t, \tau_j(y_j) + 0, y)g_j(y_j), \quad n = 0, 1, \ldots
\]

The proof of the W-almost periodicity of \( u_{n+1}(t,y) \) in space \( X^\alpha \) is similar to the proof of Theorem 1.

One can verify that for sufficiently small \( N_1 > 0 \) the sequence \( \{u_n(t,y)\} \) converges to the W-almost periodic solution \( u^*(t,y) : R \to X^\alpha \) of Eq. (63). As in the proof to Theorem 2, we prove that \( u^*(t,y) \) is the W-almost periodic solution of impulsive equation (61), (62).

Let \( t \in (\tilde{\tau}, \tilde{\tau}+1) \), where \( \tilde{\tau} = \tau(y_i) \). As in (39), we obtain

\[
\|u^*(t,y)\|_\alpha \leq \int_{-\infty}^{t} \|A^\alpha U(t, s,y)(f(s,0) + f(s,u^*(s,y)) - f(s,0))\|ds \\
+ \sum_{\tau_j(y_j) \leq t} \|U(t, \tau_j + 0, y)(g_j(0) + g_j(y_j) - g_j(0))\|_\alpha \\
\leq \frac{M_1}{1 - e^{-\beta t}} \left( \frac{C_\alpha q_1 - \alpha}{1 - \alpha} \left( M_0 + N_1 \sup \|u^*(t,y)\|_\alpha \right) + M_0 + N_1 \sup \|y_j\|_\alpha \right).
\]

Hence, \( \sup \|u^*(t,y)\| \leq \rho \), where \( \rho \) satisfies Condition 6.

If we choose the almost periodic sequence \( y^* = \{y_j^*\}, \ y_j^* \in X^\alpha \), such that

\[
u^*(\tau_j(y_j^*), y^*) = y_j^*
\]

for all \( j \in Z \), then the function \( u^*(t,y^*) \) will be exactly the W-almost period solution of Eq. (67), (68).

We consider the space \( \mathcal{N} \) of sequences \( y = \{y_j\} \), \( y_j \in X^\alpha \), with norm \( \|y\|_S = \sup_j \|y_j\|_\alpha \) and map \( S : \mathcal{N} \to \mathcal{N} \),

\[S(y) = \{u^*(\tau_j(y_j), y)\}_{j \in Z}.
\]

\( S \) maps the domain \( \mathcal{N}_0 = \{y \in \mathcal{N}, \|y\|_S \leq \rho \} \) into itself.

Now we prove that \( S \) is a contraction. Let, for definiteness, \( \tilde{\tau}_j = \tau_j(y_j) < \tilde{\tau}_j^2 = \tau_j(\tilde{z}_j) \). Then

\[
\|S(y_j) - S(z_j)\|_\alpha = \|u^*(\tau_j(y_j), y) - u^*(\tau_j(z_j), z)\|_\alpha \\
\leq \|u^*(\tilde{\tau}_j^1, y) - u^*(\tilde{\tau}_j^1, z)\|_\alpha + \|u^*(\tilde{\tau}_j^2, z) - u^*(\tilde{\tau}_j^2, z)\|_\alpha,
\]

Denote

\[
\mathcal{J} = \cup_j \mathcal{J}_j, \quad \mathcal{J}_j = (\max\{\tilde{\tau}_{j-1}, \tilde{\tau}_{j-1}^2\}, \min\{\tilde{\tau}_j, \tilde{\tau}_j^2\}) = (\tau_j^*, \tau_j^*).
\]

Denote also \( \xi_j = (\tau_j + \tau_j^*/2), \quad j \in Z \).
To estimate the difference \( \| u^*(\xi^1, y) - u^*(\xi^2, z) \|_\alpha \), we apply iteration on \( n \). Put \( u_0(t, y) = u_0(t, z) = 0 \). Then for \( t \in (\xi^0, \xi^+_1) \) we get

\[
\| u_k(t, y) - u_1(t, z) \|_\alpha = \| \sum_{k \leq i} A^\alpha U(t, \xi^1_k + 0, y) g_k(y_k) - \sum_{k \leq i} A^\alpha U(t, \xi^2_k + 0, z) g_k(z_k) \| \\
+ I_0 \leq I_0 + \sum_{k \leq i} \| A^\alpha U(t, \xi^1_k + 0, y) (g_k(y_k) - g_k(z_k)) \| + \| A^\alpha U(t, \xi^1) + 0, y) \| \\
- U(t, \xi^2_k + 0, z) g_k(z_k) \| + \sum_{k \leq i} \| A^\alpha (U(t, \xi^1_k + 0, y) - U(t, \xi^2_k + 0, z)) g_k(z_k) \| \\
\leq I_0 + \sum_{k \leq i} M_k e^{-\theta t - \xi^1_k} \| N \| \| z_k \|_\alpha + \| A^\alpha e^{-A(t - \xi^1)} (e^{-A(t - \xi^2)} - I) g_k(z_k) \| \\
+ \sum_{k \leq i} \| U(t, \xi^1_k) (U(\xi^1_k + 0, y) U(\xi^1_k + 0, y) g_k(z_k) \|_\alpha \\
- U(t, \xi^2_k) (U(\xi^2_k + 0, z) U(\xi^2_k + 0, z) g_k(z_k) \| \\
\leq I_0 + \frac{M_k \| N \| \| z_k \|_S + C_0 C_1 (t - \xi^1 \| \xi^2 \|_\alpha \| z_k \|_\alpha}{1 - e^{-\theta t}} + \| A^\alpha e^{-A(t - \xi^1)} (e^{-A(t - \xi^2)} - I) g_k(z_k) \| \\
+ \sum_{k \leq i} \| A^\alpha (U(t, \xi^1_k) - U(t, \xi^2_k)) U(\xi^1_k, \xi^2_k + 0, z) g_k(z_k) \| \\
+ \sum_{k \leq i} \| A^\alpha (U(t, \xi^1_k) - U(t, \xi^2_k)) U(\xi^1_k, \xi^2_k + 0, y) g_k(z_k) \| \\
+ \sum_{k \leq i} \| A^\alpha (U(t, \xi^2_k + 0, y) - U(\xi^2_k + 0, z)) g_k(z_k) \|, \quad (65)
\]

where

\[
I_0 = \int_{-\infty}^t \| A^\alpha (U(t, s, y) - U(t, s, z)) f(s, 0) \| ds.
\]

To evaluate the difference \( U(\xi^1_n + 0, y) - U(\xi^2_n + 0, z) \), we construct two sequences of bounded operators \( X^\alpha \rightarrow X^\alpha \) defined by

\[
T_n = U(\xi^2_n + 0, y), \quad \tilde{T}_n = U(\xi^2_n + 0, z), \quad n \in Z.
\]

The corresponding difference equations \( u_{n+1} = T_n u_n \) and \( u_{n+1} = \tilde{T}_n u_n \) are exponentially stable. Their evolution operators

\[
T_{n,m} = T_{n-1} \cdots T_m, \quad n, m, \tilde{T}_{n,m} = I,
\]

and

\[
\tilde{T}_{n,m} = \tilde{T}_{n-1} \cdots \tilde{T}_m, \quad n, m, \tilde{\tilde{T}}_{n,m} = I,
\]

satisfies equality

\[
\tilde{T}_{n,m} - T_{n,m} = \sum_{k \leq n} T_{n,k+1} (\tilde{T}_k - T_k) \tilde{T}_{k,m}, \quad n \geq m.
\]

Analogous to (32) and (33), we obtain
Almost periodic evolution equations

\[ \| T_{n,m} - T_{n,m} \|_\alpha \leq M_2 e^{-\beta_2 (n-m)} \sup_k \| T_k - T_k \|_\alpha, \; n \geq m, \]  

(66)

with some $\beta_2 \leq \beta_1, M_2 \geq M_1$.

Now we estimate the difference $\| T_n - T_n \|_\alpha$:

\[
\| T_n - \tilde{T}_n \|_\alpha = \| U(\xi_{n+1}, \xi_n, y) - U(\xi_{n+1}, \xi_n, z) \|_\alpha \\
\leq \| A^\alpha (e^{-A(\xi_{n+1}-\xi_n)}(I + B_n) e^{-A(\tilde{\xi}_n - \xi_n)} - e^{-A(\xi_{n+1}-\tilde{\xi}_n)}(I + B_n) e^{-A(\xi_n - \tilde{\xi}_n)}) \|_\alpha \\
\leq \| A^\alpha e^{-A(\xi_{n+1} - \xi_n)}(I + B_n) e^{-A(\tilde{\xi}_n - \xi_n)} - e^{-A(\xi_{n+1} - \tilde{\xi}_n)}) \|
\]

Therefore, 

\[
\| (T_{n,m} - T_{n,m})u \|_\alpha = \| (U(\xi_{n+1}, \xi_n, y) - U(\xi_{n+1}, \xi_n, z))u \|_\alpha \\
\leq 2M_2 e^{-\beta_2 (n-m)} C_\alpha C_1 (\theta/2)^{-1-\alpha} (1 + b) \sup_j \| \xi_j^1 - \tilde{\xi}_j^1 \| u \|_\alpha, \; n \geq m. \]  

(67)

To finish the estimation of (65), we consider the following two differences 

\[
\| (U(t, \xi, y) - U(t, \tilde{\xi}, z))u \|_\alpha \leq \| A^\alpha (e^{-A(t - \xi')} (I + B_t) e^{-A(t' - \tilde{\xi}_n)} - e^{-A(t' - \xi_n)}) \|_\alpha \leq \| \xi_n - \tilde{\xi}_n \|_\alpha \| u \|_\alpha. \]  

(68)

\[
\| (U(t, \xi, \tilde{\xi}_n^1 + 0, y) - U(t, \xi_n, \tilde{\xi}_n^2 + 0, z))u \|_\alpha \leq \| A^\alpha (I - e^{-A(t - \tilde{\xi}_n^1)}) e^{-A(\xi_n - \tilde{\xi}_n^2)} \|_\alpha \leq 4C_\alpha C_1 (\theta/2)^{-1-\alpha} |\tilde{\xi}_n^1 - \tilde{\xi}_n^2| \| u \|_\alpha. \]  

(69)

Taking into account (66), (68) and (69), by (65) we obtain for $t \in (\tau_i', \tau_{i+1}']$

\[
\| u_1(t, y) - u_1(t, z) \|_\alpha \leq N_1 \| y - z \|_S (K_1' + K_2''(t - \tau_i')^{-\alpha}) + I_0, \]  

(70)

where the positive constants $K_1'$ and $K_2''$ don’t depend on $i$.

Now we consider the $(n + 1)$st iteration

\[
\| u_{n+1}(t, y) - u_{n+1}(t, z) \|_\alpha = \| \int_{-\infty}^t A^\alpha U(t, \tau, y) f(\tau, u_n(\tau, y)) d\tau + \sum_{k \leq i} A^\alpha U(t, \tilde{\xi}_k^1 + 0, y) g_k(y_k) \\
- \int_{-\infty}^t A^\alpha U(t, \tau, z) f(\tau, u_n(\tau, z)) d\tau + \sum_{k \leq i} A^\alpha U(t, \tilde{\xi}_k^2 + 0, z) g_k(z_k) \|
\]

\[
\leq \int_{-\infty}^t \| A^\alpha U(t, \tau, y) (f(\tau, u_n(\tau, y)) - f(\tau, u_n(\tau, z))) \| d\tau \\
+ \int_{-\infty}^t \| A^\alpha (U(t, \tau, y) - U(t, \tau, z)) f(\tau, u_n(\tau, z)) \| d\tau.
\]
\[ + \sum_{k<i} \| A^\alpha U(t, \bar{\tau}_k^l + 0, y) (g_k(y_k) - g_k(z_k)) \| \]
\[ + \sum_{k<i} \| A^\alpha (U(t, \bar{\tau}_k^l + 0, y) - U(t, \bar{\tau}_k^l + 0, z)) g_k(z_k) \|. \] (71)

Similar to (39), we get
\[ \int_{\tau}^{t} \| A^{\alpha} e^{-A(t-\tau)} (f(\tau, u_n(\tau, y)) - f(\tau, u_n(\tau, z))) \| d\tau \]
\[ + \sum_{k<i} \int_{\tau}^{\bar{\tau}_k^l} \| A^\alpha U(t, \tau, y) (f(\tau, u_n(\tau, y)) - f(\tau, u_n(\tau, z))) \| d\tau \leq \frac{M_1}{1 - e^{-\beta_1 N_1}} \sup_{\tau \in [\tau, t]} \| u_n(\tau, y) - u_n(\tau, z) \|, \]
\[ \sum_{k<i} \| A^\alpha U(t, \bar{\tau}_k^l + 0, y) (g_k(y_k) - g_k(z_k)) \| \leq \frac{M_1}{1 - e^{-\beta_1 N_1}} N_1 \| y - z \|, \]

If \( \| u_n(\tau, y) \| \leq \rho \) and \( \| u_n(\tau, z) \| \leq \rho \), then for \( t \in (\tau', \tau_{i+1}'] \)
\[ \sum_{k<i} \int_{\tau}^{\bar{\tau}_k^l} \| A^\alpha U(t, s, y) (f(s, u_n(s, y)) - f(s, u_n(s, z))) \| ds \]
\[ \leq \sum_{k<i} \int_{\tau}^{\bar{\tau}_k^l} \| U(t, s, y) f(s, u_n(s, y)) \| ds + \sum_{k<i} \int_{\tau}^{\bar{\tau}_k^l} \| U(t, s, y) f(s, u_n(s, z)) \| ds \]
\[ \leq 2 \sum_{k<i} M_1 e^{-\beta_1 |t - \bar{\tau}_k^l|} (M_0 + N_1 \rho) + 2 \int_{\tau}^{\bar{\tau}_k^l} \| A^\alpha U(t, s, y) \| (M_0 + N_1 \rho) ds \]
\[ \leq \left( \frac{2M_1}{1 - e^{-\beta_1 N_1}} + \frac{2M_1}{1 - \alpha} (t - \bar{\tau}_k^l)^{-\alpha} \right) (M_0 + N_1 \rho) N_1 \| y - z \|, \] (72)

since for \( t > \tau_2 > \tau_1 \)
\[ \int_{\tau_1}^{\tau_2} \frac{ds}{(t - s)^\alpha} \leq \frac{\tau_2 - \tau_1}{(1 - \alpha)(t - \tau_2)^\alpha} \]

The second integral in (71) satisfies the following inequality:
\[ I_2 = \int_{-\infty}^{t} \| A^\alpha (U(t, s, y) - U(t, s, z)) f(s, u_n(s, z)) \| ds \leq \int_{\tau_1}^{t} \| A^\alpha (e^{-A(t-s)} - e^{-A(t-\tau_1)} f(s, u_n(s, z)) \| ds \]
\[ + \int_{\tau_1}^{t} \| A^\alpha (U(t, s, y) - U(t, s, z)) f(s, u_n(s, z)) \| ds \]
We consider all integrals in (73) separately.

\[
I_{21} = \int_{\xi_i}^{\xi} ||A^\alpha(U(t,s,y) - U(t,s,z))f(s,u_n(s,z))|| ds \leq \frac{C_\alpha(1 + b)(M_0 + N_1\rho)}{(1 - \alpha)(t - \xi)\alpha} ||\tau'' - \tau'||, \\
I_{22} = \int_{\xi_i}^{\xi} ||A^\alpha U(t,s,z)f(s,u_n(s,z))|| ds \leq \frac{C_\alpha(1 + b)(M_0 + N_1\rho)}{(1 - \alpha)(t - \xi)\alpha} ||\tau'' - \tau'||, \\
I_{23} = \int_{\xi_i}^{\xi} ||A^\alpha(U(t,s,y) - U(t,s,z))f(s,u_n(s,z))|| ds \\
= \int_{\xi_i}^{\xi} ||A^\alpha(U(t,\xi_1^2,y)U(\xi_1^2,\xi,\xi) - U(t,\xi_2^1,z)U(\xi_2^1,\xi,z) + \xi) f(s,u_n(s,z))|| ds \\
\leq \int_{\xi_i}^{\xi} ||A^\alpha((e^{-A(t-\xi)} - e^{-A(t-\xi_1^2)})(I + B_1)e^{-A(t-\xi)} - A^\alpha e^{-A(t-\xi_2^1)}(I + B_1)(e^{-A(t-\xi_1^2)} - e^{-A(t-\xi_2^1)}) f(s,u_n(s,z))|| ds \\
\leq \frac{2C_\alpha C_\alpha C_1 + \alpha - \alpha_1}{(1 + b)\alpha_1 - \alpha} (|\tau'' - \xi|, \quad \alpha_1 > \alpha).
\]

The last sum in (73) is transformed as follows:

\[
I_{24} = \sum_{k<i} \int_{\xi_k}^{\xi} ||A^\alpha(U(t,s,y) - U(t,s,z))f(s,u_n(s,z))|| ds \\
= \sum_{k<i} \int_{\xi_k}^{\xi} \left| \left| \left| (U(t,\xi_k,y)U(\xi_k,\xi_{k+1},y) - \xi_k) f(s,u_n(s,z)) \right| \right|_\alpha ds \\
\leq \sum_{k<i} \int_{\xi_k}^{\xi} \left| \left| (U(t,\xi_k,y) - U(t,\xi_k,z))U(\xi_k,\xi_{k+1},y) f(s,u_n(s,z)) \right| \right|_\alpha \\
+ \left| \left| (U(t,\xi_k,z)U(\xi_k,\xi_{k+1},y) - U(t,\xi_k,z)U(\xi_k,\xi_{k+1},z) f(s,u_n(s,z)) \right| \right|_\alpha \\
+ \left| \left| (U(t,\xi_k,z)U(\xi_k,\xi_{k+1},z) - U(\xi_k,\xi_{k+1},z) f(s,u_n(s,z)) \right| \right|_\alpha \right) ds.
\]

To finish the estimation of integral \(I_{24}\) we use (67), (68), (69) and

\[
\int_{\xi_k}^{\xi} \left| \left| A^\alpha(U(\xi_{k+1},s,y) - U(\xi_{k+1},s,z)) f(s,u_n(s,z)) \right| \right|_\alpha ds \\
\leq \int_{\xi_k}^{\xi} \left| \left| A^\alpha(e^{-A(\xi_{k+1}-s)}) - e^{-A(\xi_{k+1}-s)}) f(s,u_n(s,z)) \right| \right|_\alpha ds.
\]
with some positive constant \( \bar{K} \) and \( \alpha_1 > \alpha \). Therefore,

\[
I_2 \leq N_1 \left( K'_3 + \frac{K''_3}{(t - \tau'_i)^{\alpha_1}} \right) \| y - z \|_S \tag{74}
\]

with \( \alpha_1 > \alpha \) and positive constants \( K'_3 \) and \( K''_3 \) independent on \( i, k \).

By (70), (73), and (74) we obtain for \( t \in (\tau'_i, \tau'_{i+1}] \)

\[
\| u_{n+1}(t, y) - u_{n+1}(t, z) \| \leq \sum_{k < i} \int_{\tau'_i}^{\tau'_{i+1}} \| A^{\alpha} U(t, \tau, y) (f(\tau, u_n(\tau, y))) - f(\tau, u_n(\tau, z)) \| d\tau + \int_{\tau'_i}^{t} \| A^{\alpha} U(t, \tau, y) (f(\tau, u_n(\tau, y))) \| d\tau + \left( K'_3 + \frac{K''_3}{(t - \tau'_i)^{\alpha_1}} \right) N_1 \| y - z \|_S, \tag{75}
\]

where the constants \( K'_3 \) and \( K''_3 \) don't depend on \( n \).

Let the \( n \)th iteration satisfies the inequality

\[
\| u_n(t, y) - u_n(t, z) \|_\alpha \leq \left( L'_{n'} + \frac{L''_{n'}}{(t - \tau'_i)^{\alpha_1}} \right) N_1 \| y - z \|_S, \quad t \in (\tau'_i, \tau'_{i+1}],
\]

with positive constants \( L'_{n'} \) and \( L''_{n'} \). We estimate the \((n+1)\)st iteration.

\[
\| u_{n+1}(t, y) - u_{n+1}(t, z) \|_\alpha \leq \left( K'_3 + \frac{K''_3}{(t - \tau'_i)^{\alpha_1}} \right) N_1 \| y - z \|_S
\]

\[
+ N_1^2 \| y - z \|_S \sum_{k < i} \int_{\tau'_i}^{\tau'_{i+1}} \| A^{\alpha} U(t, s) \| \left( L'_{n'} + \frac{L''_{n'}}{(s - \tau'_i)^{\alpha_1}} \right) ds
\]

\[
+ N_1^2 \| y - z \|_S \int_{\tau'_i}^{t} \| A^{\alpha} U(t, s) \| \left( L'_{n'} + \frac{L''_{n'}}{(s - \tau'_i)^{\alpha_1}} \right) ds
\]

\[
\leq N_1^2 \| y - z \|_S \left( \sum_{k < i} \int_{\tau'_i}^{\tau'_{i+1}} M_k e^{-B_i|t-s|} \left( L'_{n'} + \frac{L''_{n'}}{(s - \tau'_i)^{\alpha_1}} \right) ds + \frac{L'_{n'}}{(t - \tau'_i)^{\alpha_1}} N_1 \| y - z \|_S \right)
\]
formly bounded by some constants $u$ and $\tau$

Almost periodic evolution equations

By Theorem 3.5.2, [9], at the interval $[\tau_{j-1}, \tau_j]$ the derivative satisfies

$$\|d/ds u^*(s, z)\|_Y \leq \tilde{K}_1(s - \tau_{j-1})^{\alpha - \gamma - 1}$$

with some positive constant $\tilde{K}_1$ independent of $j$ and an initial value from $U^\alpha_p$. Then for $t \in (\bar{\tau}_j^1, \bar{\tau}_j^2)$

$$\|d/ds u^*(s, z)\|_Y \leq \tilde{K}_1 \left( \frac{\theta}{2} \right)^{\alpha - \gamma - 1} = \tilde{K}_2$$

and

$$\|u^*(\bar{\tau}_j^1, z) - u^*(\bar{\tau}_j^2, z)\|_Y \leq \tilde{K}_2|\bar{\tau}_j^1 - \bar{\tau}_j^2| \leq \tilde{K}_2 N_1 \|y - z\|_S.$$  \hspace{1cm} (78)

By (77) and (78) we have

$$\|u^*(\bar{\tau}_j^1, z) - u^*(\bar{\tau}_j^2, z)\|_Y = I_0 \|y - z\|_S.$$  \hspace{1cm} (79)
where \( T_0 < 1 \) uniformly for \( j \) and \( y, z \in \mathcal{N}_\rho \).

By (64), (77) and (79) we conclude that the map \( S : \mathcal{N}_\rho \to \mathcal{N}_\rho \) is a contraction. Therefore, there exists unique almost periodic sequence \( y^* = \{y^*_j\} \) such that 
\[
\begin{align*}
&u^*(\tau_j(y^*_j), y^*_j) = y^*_j \quad \text{for all } j \in \mathbb{Z}.
&\end{align*}
\]
The function \( u^*(t, y^*) \) is W-almost periodic solution of the equation (57), (58).

2. Now we proof the stability of the almost periodic solution. Fix arbitrary \( \varepsilon > 0 \) and \( \eta > 0 \). Let \( t_0 \in [z_0(0) + \eta, z_1(0) - \eta] \).

The W-almost periodic solution \( u_0(t) \) satisfies the integral equation
\[
u_0(t) = U_0(t, t_0)u_0 + \int_{t_0}^{t} U_0(t, s)f(s, u_0(s))ds + \sum_{t_0 \leq \tau_j < t} U_0(t, \tau_j + 0)g_j(\tau_j),
\]
where \( \tau_j = \tau_j(u_0(\tau_j)) \) and \( U_0(t, s) \) is the evolution operator of the linear equation
\[
d\frac{du}{dt} + Au = 0, \quad u(\tau_j + 0) - u(\tau_j^0) = B_j u(\tau_j^0), \quad j = 1, 2, ...,
\]
Let \( u_1 \in X^\alpha \) such that \( \|u_0 - u_1\|_{\alpha} < \delta \). The solution \( u_1(t) \) with initial value \( u_1(t_0) = u_1 \) satisfies equation
\[
u_1(t) = U_1(t, t_0)u_1 + \int_{t_0}^{t} U_1(t, s)f(s, u_1(s))ds + \sum_{t_0 \leq \tau_j < t} U_1(t, \tau_j + 0)g_j(\tau_j),
\]
where \( \tau_j = \tau_j(u_1(\tau_j)) \) and \( U_1(t, s) \) is the evolution operator of the linear equation
\[
d\frac{du}{dt} + Au = 0, \quad u(\tau_j + 0) - u(\tau_j) = B_j u(\tau_j), \quad j = 1, 2, ...,
\]

By Lemma 5 for a sufficiently small Lipschitz constant \( N_1 \) the evolution operator \( U_1(t, s) \) satisfies the inequality
\[
\|U_1(t, s)u\|_{\alpha} \leq M_1 e^{-\beta_1(t-s)}\|u\|_{\alpha}, \quad t \geq s,
\]
with some positive constants \( \beta_1 \leq \beta, \quad M_1 \geq M \). Moreover, one can verify that for some domain \( U_0^{\alpha}, \rho \leq \rho \), and \( N_1 \leq N_0 \) the evolution operator \( U_1 \) satisfies
\[
\|U_1(t, s)u\|_{\alpha} \leq M_1 e^{-\beta_1(t-s)}\|u\|_{\alpha}, \quad t \geq s, \quad t, s \in [t_0, t_0 + T],
\]
if the values \( u_1(t) \) belong to \( U_0^{\alpha} \) for \( t \in [t_0, t_0 + T] \).

At the interval without impulses, the difference of solutions \( u_0(t) - u_1(t) \) satisfies the inequality
\[
\|u_1(t) - u_0(t)\|_{\alpha} \leq \|e^{-A(t-t_1)}(u_0(t_1) - u_1(t_1))\|_{\alpha}
+ \int_{t_1}^{t} \|A e^{-A(t-s)}(f(s, u_0(s)) - f(s, u_0(s)))\|ds
\]
Then by Lemma [2]

$$||u_1(t) - u_0(t)||_\alpha \leq M_1C e^{-\beta_1(t-t_1)}||u_1(t_1) - u_0(t_1)||_\alpha, \ t - t_1 \leq Q.$$  \hfill (82)

Hence, if initial values belong to the bounded domain from $X^\alpha$, then the corresponding solutions are uniformly bounded for $t$ from the bounded interval.

Assume for definiteness that $\tau^0_j \geq \tau^1_j$ and estimate $|\tau^j - \tau^0_j|$ by $(u_1(\tau^j_1) - u_0(\tau^j_1))$.

By [73]

$$||u_0(\tau^0_j) - u_0(\tau^1_j)||_\alpha \leq ||u_0(\tau^0_j) - u_0(\tau^1_j)||_\alpha + ||u_0(\tau^1_j) - u_1(\tau^1_j)||_\alpha$$

$$\leq \int_{\tau^0_j}^{\tau^1_j} \frac{d}{d\xi} u_0(\xi) d\xi \leq ||u_0(\tau^1_j) - u_1(\tau^1_j)||_\alpha$$

$$\leq \bar{K}_2|\tau^0_j - \tau^1_j| + ||u_0(\tau^1_j) - u_1(\tau^1_j)||_\alpha.$$  \hfill (83)

Hence,

$$|\tau^0_j - \tau^1_j| \leq N_1 ||u_0(\tau^0_j) - u_1(\tau^1_j)||_\alpha \leq \frac{N_1}{1 - \bar{K}_2N_1} ||u_0(\tau^1_j) - u_1(\tau^1_j)||_\alpha.$$  \hfill (84)

Denote $\tau^*_j = \min\{\tau^0_j, \tau^1_j\}$, $\tau^*_j = \max\{\tau^0_j, \tau^1_j\}$, $j = 1, 2, \ldots$. We assume that $t \in (\tau^*_j, \tau^{*+1}_j)$ and estimate the difference

$$||u_0(t) - u_1(t)||_\alpha = ||U_0(t,t_0)(u_0 - u_1)||_\alpha + ||U_0(t,t_0) - U_1(t,t_0)||u_1||_\alpha$$

$$+ \int_{t_0}^{t} \|U_0(t,s)f(s,u_0(s)) - U_1(t,s)f(s,u_1(s))\|_\alpha ds$$

$$+ \|\sum_{t_0 < \tau^*_j < t} U(t, \tau^*_j + 0)g_j(\tau^*_j) - \sum_{t_0 < \tau^*_j < t} U(t, \tau^*_j + 0)g_j(\tau^*_j)\|_\alpha$$

$$\leq ||U_0(t,t_0)(u_0 - u_1)||_\alpha + ||U_0(t,t_0) - U_1(t,t_0)||u_1||_\alpha$$

$$+ \int_{t_0}^{t} \|U_0(t,s)f(s,u_0(s)) - U_1(t,s)f(s,u_1(s))\|_\alpha ds$$

$$+ \sum_{j=1}^{i-1} \int_{\tau^*_j}^{\tau^{*+1}_j} \|U_0(t,s)f(s,u_0(s)) - U_1(t,s)f(s,u_1(s))\|_\alpha ds$$

$$+ \sum_{j=1}^{i-1} \int_{\tau^*_j}^{\tau^{*+1}_j} \|U_0(t,s)f(s,u_0(s)) - U_1(t,s)f(s,u_1(s))\|_\alpha ds$$

$$+ \int_{\tau^*_j}^{t} \|U_0(t,s)f(s,u_0(s)) - U_1(t,s)f(s,u_1(s))\|_\alpha ds$$

$$+ \sum_{j=1}^{i} \int_{\tau^*_j}^{\tau^*_j} \|U_0(t,s)f(s,u_0(s)) - U_1(t,s)f(s,u_1(s))\|_\alpha ds$$

$$+ \int_{\tau^*_j}^{t} ||u_0(t,s) - u_1(t,s)||f(s,u_1(s))|_\alpha ds$$

$$+ \int_{\tau^*_j}^{t} ||u_0(t,s) - u_1(t,s)||f(s,u_1(s))|_\alpha ds.$$
Hence, for 

\[ 34 \text{ Viktor Tkachenko} \]

that there exist positive constants \( M \) and \( \eta \). By (82), analogously to the proof of (70), (73), and (74), we conclude that there exist positive constants \( M_2 \) and \( P_1 \) independent of \( i \) such that for \( t \in \mathcal{J}_{i+1} \)

\[
v(t) \leq M_1 e^{-\beta_1(t-t_0)} v(t_0) + \int_{t_0}^t M_2 N_1 e^{-\beta_1(t-\tau_i')} v(s)ds \\
+ \sum_{j=2}^{i-1} \int_{\tau_{i-1}}^{\tau_i} M_2 N_1 e^{-\beta_1(t-\tau_j')} v(s)ds + \sum_{j=1}^{i-1} P_1 N_1 e^{-\beta_1(t-\tau_j')} v(\tau_j') \\
+ \frac{1}{(t-\tau_i')} \left( \int_{\tau_{i-1}}^{\tau_i} M_2 N_1 e^{-\beta_1(t-s)} v(s)ds + P_1 N_1 e^{-\beta_1(t-\tau_i')} v(\tau_i') \right) \\
+ \int_{\tau_i}^{t} M_2 N_1 e^{-\beta_1(t-s)} (t-s)^{-\alpha_1} v(s)ds, \quad \alpha_1 > \alpha. \tag{85}
\]

Denote \( \tilde{Q} = \max_j \{ 1, (\tau_{j+1}' - \tau_j') \} \), \( \tilde{\theta} = \min_j \{ 1, (\tau_{j+1}' - \tau_j') \} \), \( P_2 = P_1 e^{\beta_1 \sup_j |\tau_j' - \tau_j|} \), \( M_3 = M_2 e^{\beta_1 \tilde{Q}} \). By (82), at the interval \([t_0, \tau_i']\) the function \( v(t) \) satisfies

\[
v(t) \leq M_1 \tilde{C} e^{-\beta_1(t-t_0)} v(t_0), \quad t \in [t_0, \tau_i']. \tag{86}
\]

By (85) and (86), for \( t \in (\tau_i', \tau_2'] \) we get

\[
v(t) \leq M_1 e^{-\beta_1(t-t_0)} v(t_0) + \frac{1}{(t-\tau_i')} \int_{t_0}^t M_2 N_1 e^{-\beta_1(t-s)} v(s)ds \\
+ P_1 N_1 e^{-\beta_1(t-\tau_i')} (t-\tau_i')^{-\alpha_1} v(\tau_i') + \int_{\tau_i}^{t} M_2 N_1 e^{-\beta_1(t-s)} (t-s)^{-\alpha_1} v(s)ds.
\]

Hence, for \( v_1(t) = e^{\beta_1 t} v(t) \)

\[
v_1(t) \leq M_1 v_1(t_0) \left( 1 + \frac{N_1 \tilde{C} (M_2 \tilde{Q} + P_2)}{(t-\tau_i')^{\alpha_1}} \right) + \int_{\tau_i}^{t} M_2 N_1 (t-s)^{-\alpha_1} v_1(s)ds.
\]

By Lemma[2]

\[
v(t) \leq M_1 \tilde{C}_1 v(t_0) e^{-\beta_1(t-t_0)} \left( 1 + \frac{N_1 \tilde{C} (M_2 \tilde{Q} + P_2)}{(t-\tau_i')^{\alpha_1}} \right), \quad t \in (\tau_i', \tau_2'],
\]

where \( \tilde{C}_1 \) is defined by (2).

Let us prove that \( v(t) \leq \)}
Almost periodic evolution equations

\[ \leq M_1 \tilde{C}_1 v(t_0) e^{-\beta_1 (t-t_0)} \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(t - \tau_{n}^\prime)^{\bar{\alpha}_1}} \right) \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(1 - \bar{\alpha}_1) \theta^{\bar{\alpha}_1}} \right)^{(i-1)} \]  

\[ (87) \]

for \( t \in (\tau_{n}^\prime, \tau_{n+1}^\prime), \; i \geq 2 \). We apply the method of mathematical induction. Assume that \((87)\) is true for \( t \in (\tau_{n-1}^\prime, \tau_{n}^\prime) \) and prove it for \( t \in (\tau_{n}^\prime, \tau_{n+1}^\prime) \). Really, by \((85)\) for \( t \in (\tau_{n}^\prime, \tau_{n+1}^\prime) \) we have

\[ v(t) \leq M_1 e^{-\beta_1 (t-t_0)} v(t_0) \left( 1 + (M_2 \bar{Q} + P_2) N_1 \tilde{C}_1 \right) \]

\[ + \sum_{j=2}^{n-1} \mathcal{A}^j M_2 N_1 \tilde{C}_1 + \sum_{j=2}^{n-1} \mathcal{A}^{j-1} \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(1 - \bar{\alpha}_1) \theta^{\bar{\alpha}_1}} \right) N_1 P_2 \tilde{C}_1 \]

\[ + \mathcal{A}^{n-2} \left( N_1 M_2 \tilde{C}_1 \left( \tau_{n}^\prime - \tau_{n}^\prime \right) + N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2) \right) \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(1 - \bar{\alpha}_1) \theta^{\bar{\alpha}_1}} \right) \]

\[ + N_1 P_2 \tilde{C}_1 \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(1 - \bar{\alpha}_1) \theta^{\bar{\alpha}_1}} \right) + \mathcal{B}_n(t) \]

where

\[ \mathcal{A} = \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(1 - \bar{\alpha}_1) \theta^{\bar{\alpha}_1}} \right), \quad \mathcal{B}_n(t) = \int_{\tau_{n}^\prime}^{t} \frac{M_2 N_1}{(t - x)^{\bar{\alpha}_1}} e^{-\beta_1 (t-s)} v(s) ds. \]

Hence, for \( t \in (t_n, t_{n+1}) \), the function \( v_1(t) \) satisfies the inequality

\[ v_1(t) \leq \mathcal{A}^{n-1} \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{(1 - \bar{\alpha}_1) \theta^{\bar{\alpha}_1}} \right) + M_2 N_1 \int_{\tau_{n}^\prime}^{t} (t-s)^{-\bar{\alpha}_1} v_1(s) ds. \]

Applying Lemma\[2\] we obtain \((87)\).

Let \( N_1 > 0 \) be such that \( \mathcal{A}^{n-1} e^{-\beta_1 (t-t_0)} < e^{-\delta_1 (t-t_0)} \) for some positive \( \delta_1 \). For given \( \varepsilon > 0 \) and \( \eta > 0 \) we choose \( v(t_0) = v_0 \) such that

\[ M_1 \tilde{C}_1 v_0 \left( 1 + \frac{N_1 \tilde{C}_1 (M_2 \bar{Q} + P_2)}{\eta^{\bar{\alpha}_1}} \right) < \varepsilon. \]

This proves the asymptotic stability of solution \( u_0(t) \).

**Example 1.** Let us consider the parabolic equation with impulses in variable moments of time

\[ u_t = u_{xx} + a(t) u_x + b(t,x), \]

\[ (88) \]
\[ \Delta u \bigg|_{t = \tau_j(u)} = u(\tau_j(u) + 0, x) - u(\tau_j(u), x) = -a_j u(\tau_j(u), x), \quad (89) \]

with boundary conditions

\[ u(t, 0) = u(t, \pi) = 0, \quad (90) \]

where the sequence of real numbers \( \{ \tau_j \} \) is defined by

\[ \tau_j(u) = \theta_j + b_j \int_0^\pi u^2(\xi) d\xi, \quad j \in \mathbb{Z}, \]

where the sequence of real numbers \( \{ \theta_j \} \) has uniformly almost periodic sequences of differences and \( \theta_{j+1} - \theta_j \geq \theta \geq 1/2, \)

\( \{ a_j \} \) and \( \{ b_j \} \) are almost periodic sequences of positive numbers,

\( a(t) \) is a Bohr almost periodic function,

\( b(t, x) \) is a Bohr almost periodic function in \( t \) uniformly with respect to \( x \in [0, \pi] \)

and belongs to \( L_2(0, \pi) \) for all fixed \( t. \)

Denote

\[ X = L_2(0, \pi), \quad A = -\frac{\partial^2}{\partial x^2}, \quad X^1 = D(A) = H^2(0, \pi) \cap H^1_0(0, \pi). \]

The operator \( A \) is sectorial with simple eigenvalues \( \lambda_k = k^2 \) and corresponding eigenfunctions

\[ \varphi_k(x) = \left( \frac{2}{\pi} \right)^{1/2} \sin kx, \quad k = 1, 2, \ldots \]

The operator \( (-A) \) generates an analytic semigroup \( e^{-At}. \) Let \( u = \sum_{k=1}^\infty a_k \sin kx, a_k = \frac{1}{\pi} \int_0^\pi u(x) \sin kxdx. \) Then

\[ Au = \sum_{k=1}^\infty k^2 a_k \sin kx, \quad A^{\alpha} u = \sum_{k=1}^\infty k^{2\alpha} a_k \sin kx, \quad e^{-At} = \sum_{k=1}^\infty e^{-k^2 t} a_k \sin kx. \]

Hence,

\[ X^{1/2} = D(A^{1/2}) = H^1_0(0, \pi). \]

Let us consider Eq. \( (88) - (90) \) in space \( X^{1/2} = D(A^{1/2}) = H^1_0(0, \pi) : \)

\[ \frac{du}{dt} + Au = f(t, u), \quad u(\tau_j(u) + 0) = (1 - a_j) u(\tau_j(u)), \quad j \in \mathbb{Z}, \]

where \( f(t, u) : \mathbb{R} \times X^{1/2} \to X, \quad f(t, u)(x) = a(t) u_x + b(t, x). \)

We verify that in some domain \( \mathcal{D} = \{ u \geq 0, ||u|| \leq \rho \} \) solutions of \( (88) - (90) \) don’t have beating at the surfaces \( t = \tau_j(u). \) Assume to the contrary that solution \( u(t) \) intersects the surface \( t = \tau_j(u) \) at two points \( t_j^1 \) and \( t_j^2, t_j^1 < t_j^2. \)
Therefore, equation (4.1) without impulses exist for all \( t \geq t_0 \) have the equation has an asymptotically stable W-almost periodic solution. This contradicts our assumption.

Denote \( u(t_j^+) = u_1, u(t_j^-) = u_2, \bar{u} = e^{-A(t_j^- - t_j)}u(t_j^+ + 0) \). Then \( u(t_j^+ + 0) = (1 - \alpha_j)u_1, \tau_j(u_1) = t_j^1, \tau_j(u_2) = t_j^2 \), and

\[
-u_2 = e^{-A(t_j^- - t_j)}u(t_j^+ + 0) + \int_{t_j^1}^{t_j^2} e^{-A(t_j - s)} f(s,u(s))ds.
\]

We have

\[
\begin{align*}
|\tau_j(u_2) - \tau_j(\bar{u})| & \leq b_j \int_0^\infty |(u_2(t,x) - \bar{u}(t,x))(u_2(t,x) + \bar{u}(t,x))|dx \\
& \leq b_j \|u_2(t,x) - \bar{u}(t,x)\|_{L_2} \|u_2(t,x) + \bar{u}(t,x)\|_{L_2} \\
& \leq b_j \int_{t_j^1}^{t_j^2} \|e^{-A(t_j - s)}f(s,u(s))\|_{L_2} \|u_2(t,x) + \bar{u}(t,x)\|_{L_2}.
\end{align*}
\]

The function \( f(t,u) \) satisfies \( \|f(t,u)\|_{X} \leq K(1 + \|u\|_{X^{1/2}}) \); hence, solutions of the equation without impulses exist for all \( t \geq t_0 \) and there exist positive constants \( M_1 \) and \( M_2 \) such that \( M_2 \geq \sup_{a \in \mathcal{P}} \|f(t,u)\|_{L_2}, M_5 \geq \sup_{a \in \mathcal{P}} \|u_2(t,x) + \bar{u}(t,x)\|_{L_2} \). Therefore, \( |\tau_j(u_2) - \tau_j(\bar{u})| \leq b_j |t_j^2 - t_j^1|M_2M_5 \). By sufficiently small \( b = \sup_j b_j \) we have \( bM_2M_5 < 1 \) and

\[
0 < t_j^2 - t_j^1 = \tau_j(u_2) - \tau_j(u_1) \leq \tau_j(u_2) - \tau_j(\bar{u}) + \tau_j(\bar{u}) - \tau_j(u_1),
\]

\[
t_j^2 - t_j^1 \leq \frac{1}{1 - bM_2M_5} (\tau_j(\bar{u}) - \tau_j(u_1)) \leq \frac{b_j(1 - \alpha_j)^2 - 1}{1 - bM_2M_5} \|u_1\|_{L_2} < 0.
\]

This contradicts our assumption.

Corresponding to (88) - (90), the linear impulsive equation is exponentially stable in space \( X^{1/2} \). By Theorem 4, for sufficiently small \( b = \sup_j b_j \) and \( a = \sup_j |a(t)| \) the equation has an asymptotically stable W-almost periodic solution.

### 6 Equations with unbounded operators \( B_j \). 

Many results in our paper remain true if operators \( B_j \) in linear parts of impulsive action are unbounded. We refer to [27], where the following semilinear impulsive differential equation

\[
\frac{du}{dt} = Au + f(t,u), \quad t \neq \tau_j,
\]

\[
\Delta u|_{t=\tau_j} = u(\tau_j) - u(\tau_j - 0) = B_ju(\tau_j - 0) + g_j(u(\tau_j - 0)), \quad j \in \mathbb{Z},
\]

was studied. Here \( u : R \to X, X \) is a Banach space, \( A \) is a sectorial operator in \( X \), \( \{B_j\} \) is a sequence of some closed operators, and \( \{\tau_j\} \) is an unbounded and strictly increasing sequence of real numbers. Assume that the equation satisfies conditions (H1), (H3), (H5), (H6) and
(H4u) the sequence \( \{B_j\} \) of closed linear operators \( B_j \in L(X^{\alpha+\gamma}, X^\alpha) \) is almost periodic in the space \( L(X^{\alpha+\gamma}, X^\alpha) \), for \( \alpha \geq 0 \) and some \( \gamma > 0 \).

As in [17], we assume that solutions \( u(t) \) of \( \text{(91)} \), \( \text{(92)} \) are right-hand-side continuous; hence \( u(t_j) = u(t_j + 0) \) at all points of impulsive action. Due to such a selection we avoid considering operators \( e^{-A(t-t_j)}(I + B_j) \) with unbounded operators \( B_j \) and can work with the family of bounded operators \( e^{-A(t-t_j)} \).

Since the operator \( A \) is sectorial and operators \( B_j \) are subordinate to \( A \), an evolution operator of a corresponding linear impulsive equation is constructed correctly. Now analogs of the theorems \( \text{(12)} \) and \( \text{(13)} \) can be proved.

**Example 2.** \([27]\). We consider the following parabolic equation with impulsive action:

\[
\begin{align*}
  u_t &= u_{xx} + f(t,x), \quad (93) \\
  \Delta u \bigg|_{t=t_j} &= u(t_j, x) - u(t_j - 0, x) = b_1 \sin(x)u_x + c_1 x(\pi - x), \quad (94)
\end{align*}
\]

with boundary conditions

\[
u(t, 0) = u(t, \pi) = 0, \quad (95)\]

where \( \{t_j\} \) is a sequence of real numbers with uniformly almost periodic sequences of differences, \( t_{j+1} - t_j \geq \theta \geq 1/2 \),

\( \{b_j\} \) and \( \{c_j\} \) are almost periodic sequences of real numbers,

\( f(t, x) \) is almost periodic and locally Holder continuous with respect to \( t \) and for every fixed \( t \) belongs to \( L_2(0, \pi) \).

As in Example 1, denote

\[
X = L_2(0, \pi), \quad A = -\frac{\partial^2}{\partial x^2}, \quad X^1 = D(A) = H^2(0, \pi) \cap H^1_0(0, \pi).
\]

The operator \( A \) is sectorial with simple eigenvalues \( \lambda_k = k^2 \) and corresponding eigenfunctions \( \phi_k(x) = \sin(kx), k = 1, 2, \ldots \).

If \( u = \sum_{k=1}^{\infty} a_k \sin(kx), \ a_k = \frac{1}{\pi} \int_0^\pi u(x) \sin(kx)dx \), then

\[
B_j u = b_j \sin x u_x = b_j \sin x \sum_{k=1}^{\infty} a_k k \cos(kx) = \frac{b_j}{2} (R - L) A^{1/2} u = b_j T A^{1/2} u,
\]

where \( Ru = \sum_{k=1}^{\infty} a_k \sin(k-1)x \) and \( Lu = \sum_{k=1}^{\infty} a_k \sin(k+1)x \) are bounded shift operators in \( X \). Hence, operators \( B_j : X^{\alpha+1/2} \to X^\alpha \) are linear continuous, \( \alpha \geq 0 \).

Analogous to \([15]\), the evolution operator for homogeneous equation \( \text{(93)}, \text{(94)} \) is

\[
U(t, s) = e^{-A(t-s)}, \quad \text{if} \quad \tau_k \leq s \leq t < \tau_{k+1},
\]

and

\[
U(t, s) = e^{-A(t-\tau_k)}(I + B_k)e^{-A(\tau_k-\tau_{k-1})} \cdots (I + B_0)e^{-A(\tau_0-s)}
\]
Let $p \ln(1 + b) < 1$, where $p$ is defined by (7) and $b = \sup_j |b_j|$. Then equation (93), (94) with boundary conditions (95) has a unique W-almost periodic solution which is asymptotically stable.

Proof. We show that the unique almost periodic solution of (93) and (94) is given as function $R \rightarrow L_2(0, \pi)$ by formula

$$u_0(t) = \int_{-\infty}^t U(t, s) \bar{f}(s) ds + \sum_{\tau_j \leq t} U(t, \tau_j) \bar{g}_j,$$

where $\bar{f}(t) = f(t, \cdot) : R \rightarrow L_2(0, \pi), \bar{g}_j(x) = c_jx(\pi - x), \bar{g}_j = g_j(\cdot) : Z \rightarrow L_2(0, \pi)$.

First, $u_0(t)$ is bounded in space $X^a$. If $t \in [\tau_i, \tau_{i+1})$ then

$$\int_{-\infty}^t \|U(t, s)\|_\infty ds \leq \int_{\tau_{i-1}}^{\tau_i} \|A^a e^{-A(t-\tau_i)} (I + B_1)e^{-A(\tau_{i-1})} \bar{f}(s)\| ds$$

$$+ \int_{\tau_i}^{\tau_{i+1}} \|A^a e^{-A(t-\tau_i)} \bar{f}(s)\| ds + \sum_{k=2}^m \int_{\tau_{i-k}}^{\tau_{i-k+1}} \|A^a e^{-A(t-\tau_i)} (I + B_1)e^{-A(\tau_{i-1})}\| d\tau$$

$$\times \prod_{j=i-1}^{i+k-2} \|(I + B_1)e^{-A(\tau_{j-1})}\| \|(I + B_{i-k+1})e^{-A(\tau_{i-1})}\| \|\bar{f}(s)\| ds,$$  \hspace{1cm} (96)

Next, we need the following inequality (see \cite{17}, p. 35):

$$\|A^a T A^b e^{-At}\| = \frac{1}{2} \|A^a (R - L) A^b e^{-At}\| \leq \frac{4^a + 1}{2} \|A^a + b e^{-At}\|.$$  \hspace{1cm} (97)

Then by (97):

$$\|A^a e^{-A(t-\tau_i)} (I + B_1)e^{-A(\tau_{i-1})}\| \leq \|A^a e^{-A(t-\tau_i)}\| + \frac{5}{2} \|A^{a+1/2} e^{-A(t-\tau_i)}\|$$

$$\leq \left(C_a(t-s)^{-\alpha} + \frac{5}{2} C_{a+1/2} (t-s)^{-(a+1/2)}\right) e^{-\delta(t-s)}.$$  \hspace{1cm} (98)

From Henry \cite{9}, p. 25, we have

$$\|A^a e^{-At}\| \leq b_\alpha(t)\|\psi\|,$$

where $b_\alpha(t) = (te/\alpha)^{-\alpha}$ if $0 < t \leq \alpha / \lambda_1$, and $b_\alpha(t) = \lambda_1^a e^{-b_\lambda t}$ if $t \geq \alpha / \lambda_1$. Since $\|T\| = 1$, and $\lambda_1 = 1$, we have

$$\|(I + B_1)e^{-A(\tau_{i-1})}\| \leq \|e^{-A(\tau_{i-1})}\| + \|b_\alpha(T) e^{A(\tau_{i-1})}\|$$

$$\leq (1 + |b_\lambda|) e^{-(\tau_{i-1})}.$$  \hspace{1cm} (99)

Let $0 < \epsilon_1 < 1 - p \ln(1 + b)$. Then there exists a positive integer $k_1$ such that for $k \geq k_1$

$$\|A^a e^{-At}\| \leq \epsilon_1 \|\psi\|.$$  \hspace{1cm} (100)
$$\frac{i(\tau_{i-k}, \tau_i)}{\tau_i - \tau_{i-k}} \ln(1 + b) - 1 < -\varepsilon_1.$$ 

Denote $N_1 = \max_{1 \leq k \leq k_1} \exp\left(i(\tau_{i-k}, \tau_i) \ln(1 + b) - (\tau_i - \tau_{i-k})\right)$. Then

$$\prod_{j=i-k+1}^{i} \left\| (I + B_j) e^{-A(\tau_{j} - \tau_{j-1})} \right\| \leq (1 + b)^i(\tau_{i-k}, \tau_i) e^{-(\tau_{i-k}, \tau_i)}$$

$$\leq N_1 e^{-\varepsilon_1 (\tau_i - \tau_{i-k})} \leq N_1 e^{-\varepsilon_1 \theta k}. \quad (99)$$

For $t \in (\tau_i, \tau_{i+1})$, by (98) and (99) we get

$$\left\| U(t, \tau_{i-k}) \right\|_\alpha \leq \left\| A^\alpha e^{-A(t - \tau_i)} (I + B_i) e^{-A(\tau_i - \tau_{i-1})} \right\| \times$$

$$\times \prod_{j=i-k+1}^{i-1} \left\| (I + B_j) e^{-A(\tau_j - \tau_{j-1})} \right\| \leq K_1 e^{-\varepsilon_1 (t - \tau_{i-k})}$$

with constant $K_1$ independent of $t$ and $\tau_{i-k}$.

Using the last inequality, we obtain the boundedness of $\|u_0(t)\|_\alpha$. We can now proceed analogously to the proof of Theorem 1 and show the almost periodicity of $u_0(t)$.
