Abstract
According to AdS/CFT duality semi-classical strings in the Schrödinger space-time is conjectured to be a holographic dual to dipole CFT. In this paper we consider pulsating strings in five-dimensional Schrödinger space times five-sphere. We have found classical string solutions pulsating entirely in the Schrödinger part of the background. We quantize the theory semi-classically and obtain the wave function of the problem. We have found the corrections to the energy, which by duality are supposed to give anomalous dimensions of certain operators in the dipole CFT.

1 Introduction
In the last two decades the celebrated AdS/CFT correspondence has proven to be a powerful tool for studying important aspects of string theory and conformal field theories. First thing to take care of is to establish a dictionary between objects on both sides of the duality. Started with examples of theories with high amount of supersymmetry in supergravity approximation, the correspondence has been developed beyond this approximation, namely taking into account essentially string modes. Although solving exactly the string spectrum on a generic background is highly non-trivial problem, the discovery of rich set of integrable structures within the correspondence allowed the fruitful study of many string configurations. In this context, a large variety of rotating strings, spinning strings, giant magnons, folded strings, spiky strings, pulsating strings and their gauge theory duals have been analyzed in great details.

Addressing the important issues as strong coupling phenomena, it became of great interest to extend it to less supersymmetric theories, which are phenomenologically more appropriate. From gravitational point of view, breaking supersymmetry means deformation of the geometry, such that the new background is again an Einstein manifold. The

\textsuperscript{*}Emails: h_dimov,rash,vetsov@phys.uni-sofia.bg and miroslavsky@abv.bg
remarkably simple procedure advocated in [1] enables to explicitly generate new solutions as well as to suggest what holographic duals of these solutions could be. This approach is based on the global symmetries underlying undeformed theory. Concretely, having two global $U(1)$ isometries one can interpret them geometrically as a two-torus. The action of the associated $SL(2,\mathbb{R})$ symmetry on the torus parameter is $\tau \rightarrow \tilde{\tau} = \tau/(1 + \gamma \tau)$. Specializing to type IIB backgrounds, it is known that we already have $SL(2,\mathbb{R})$ symmetry of ten dimensional background. The two $SL(2,\mathbb{R})$ symmetries get combined to form $SL(3,\mathbb{R})$ (which can be seen compactifying M-theory on $T^3$). The explicit form of the $SL(3,\mathbb{R})$ matrix used to generate non-singular solutions is

$$g_3 = \begin{pmatrix} 1 & 0 & 0 \\ \gamma & a & b \\ \sigma & c & d \end{pmatrix} \in SL(3,\mathbb{R}), \quad g_2 = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2,\mathbb{R}). \quad (1.1)$$

From holographic point of view however it is important where in the space-time the two-torus associated with the global isometries lives. Indeed, if the torus lives entirely in the (asymptotically) AdS part of the background geometry the dual gauge theory becomes non-commutative. The $U(1)$ charges are actually momenta and the product in the field theory is replaced by star-product. If however the torus is in the complementary part, in the field theory the product is the ordinary product, but the theory exhibits a Leigh-Strassler deformation [3]. Since the deformation uses a direction along the R-symmetry it is quite clear that the supersymmetry in the new theory will be at least partially broken. This is in agreement with the gauge theory side [3].

Gauge theories with deformed products of fields and their string theory duals, obtained with or without the knowledge of the $SL(2,\mathbb{R})$ transformation, have been thoroughly studied in the literature. Some recent advancements on the study of Lunin-Maldacena background can be found for instance in [2, 7–15].

The solution generating technique can be applied to wide range of cases. The most well-known example is probably the one of exactly marginal deformations of (super) conformal gauge theories, such as the deformations of $\mathcal{N} = 4$ Super Yang-Mills theory, considered in [3], whose gravity dual (for the so-called $\beta$-deformation) was derived in [1].

Another important case leading to qualitatively different solutions is the one dual to "dipole" theories [4–6]. It is characterized with non-locality of the dual gauge theory but still living on an ordinary commutative space. One direction, where these solutions have been used, is in description of ordinary $\mathcal{N} = 1$ SQCD-like gauge theories in the context of D-brane realizations. This type of deformations are typically used to decouple spurious effects coming from Kaluza-Klein modes on cycles wrapped by the D-brane [9–13].

Recently there has been revival of interest to holography in Schrödinger backgrounds. It has been inspired by the attempts to generalize the AdS/CFT correspondence to strongly coupled non-relativistic conformal theories [20, 21]. In these cases the isometry group of the background geometry on string side is the Schrödinger group. It consists of time and space translations, space rotations, Galilean boosts and dilatations. It has been shown that one possible dual to such theory could be dipole theories. Further progress of this line of investigations can be traced for instance in [4–6]. An important step has been done in [19] where strong arguments for integrability and quantitative check of the matching between string and gauge theory predictions have been presented. This triggered a new interest to holography in such backgrounds, since this opens the option to get important information for dipole theories for instance. Particular string solutions beyond the supergravity approximation has been found in [19, 25–27]. A semiclassical quantization has been also considered in [28].
In this paper we focus on the duality with non-relativistic gauge theory dual. This means that we have to consider background respecting Schrödinger symmetry. On the gauge theory side the theories are known as non-relativistic duals. To obtain the Schrödinger background we will use TsT deformations, which involve the time direction and one spatial dimension in the internal space. As it was shown for instance in [17], the generated solutions are twisted and the supersymmetry becomes completely broken. We will describe this technique in some details in the next Section, where we will also briefly review pulsating strings in holography. In the paper we restrict our considerations to the bosonic sector of the theory.

2 How to generate Schrödinger backgrounds

We first begin with an overview of the methods of deformations used later to generate Schrödinger spaces.

The purpose of the solution-generating technique suggested in [1] is to obtain the gravity duals of the deformed gauge theories or such with reduced (super)symmetry. Starting from a supergravity solution of a type II theory, applying a simple procedure called TsT transformation, one obtains another supergravity solution. The procedure of TsT transformation is described as follows. First of all, one has to identify two isometry directions which can be thought of as two-torus. Let us parametrize the two torus angles by $(\phi_1, \phi_2)$. The transformation then consists of a T-duality along $\phi_1$, followed by a shift $\phi_2 \rightarrow \phi_2 + \gamma \phi_1$ in the T-dual background. The final step is to T-dualize back along $\phi_1$.

This simple but remarkably effective transformations can be readily applied to a number of backgrounds, having these properties and particular, in the contexts of string/gauge theory duality.

Depending on where the isometry directions involved in TsT transformations live, we distinguish three cases of deformations:

1. To implement the first class of deformations, we take the two isometries involved in the TsT-transformation to be along the brane. In this case the product of the fields in the dual gauge theory becomes:

$$ (f \ast g)(x) = e^{-i\pi \gamma \left( \frac{\partial}{\partial x} \frac{\partial}{\partial y} - \frac{\partial}{\partial y} \frac{\partial}{\partial x} \right)} f(x)g(y)_{x=y} $$

$$ = f(x)g(x) - i\pi \gamma \left( \partial_1 f(x) \partial_2 g(x) - \partial_2 f(x) \partial_1 g(x) \right) + \cdots $$  

(2.1)

Since gamma is constant, one can easily recognize this product as the Moyal product for a non-commutative two-torus. One should note also that this deformation makes the theory non-commutative. Obviously it is non-local and breaks Lorentz invariance and causality. Nevertheless, this picture, and its generalizations, opens the road to interesting string realizations of non-commutative theories. The generalization to more non-commutative directions is straightforward.

2. To make the second class of deformations we assume that there is one global $U(1)$ isometry along the D-brane, but the other one, which is going to be used for TsT-transformation, is transversal to the brane. If we associate charges to the isometries, say $Q^i$, one can map the string picture to the gauge theory dual. In this case one of the charges remains to be the momentum but the other one is not anymore. The deformed product of the fields in this case can be read off:

$$ (f \ast g)(x) = e^{\pi \gamma \left( \frac{\partial}{\partial x} \frac{\partial}{\partial y} - \frac{\partial}{\partial y} \frac{\partial}{\partial x} \right)} f(x + \pi \gamma Q^i)g(x - \pi \gamma Q^i) $$  

(2.2)
This is called dipole deformation. As we can see it is clearly non-local in one direction, but still living on a commutative space-time. Here, we applied TsT-transformation shifting single direction \( x \), but we can obtain more general deformations by introducing “dipole vectors”, \( L^M\mu = -2\pi \gamma Q^M L^\mu \), for the various fields (here \( L^\mu \) is a constant vector). In this case, the product of the fields is

\[
(f \ast g)(x) = f(x - \frac{1}{2}L^g)g(x + \frac{1}{2}L^f).
\]

(2.3)

3. Finally, the last case involves two isometries transverse to the D-brane. The dual gauge theory picture changes since the two charges does not act as derivatives. Thus, the product of the fields reduces to

\[
(f \ast g)(x) = e^{i\pi \gamma (Q^f_1 Q^g_2 - Q^f_2 Q^g_1)} fg.
\]

(2.4)

In this case, the product deformation yields an ordinary commutative and local theory, since the only contribution to the deformed product (2.4) is to introduce some phases in the interactions. The superconformal gauge theories, arising from the product (2.4), are classified by Leigh and Strassler and are called \( \beta \)-deformed. One can note that the deformation reduces the amount of supersymmetry and TsT-transformations can serve as supersymmetry breaking procedure.

The most general deformation, which contains the above-mentioned techniques is based on the so-called Drinfeld-Reshetikhin (DR) twist. For completeness, in an Appendix A we give a very brief review of these deformations following mainly [19].

It is well known that the dipole deformations have as a dual non-relativistic theory, see for instance [4–6]. In general, the deformations, related to non-relativistic theories, are a little bit specific and we collect here in a systematic way the known facts from the literature. The procedure of the solution generating technique, we will follow below, consists in the following steps:

1. The starting point is a solution of type IIA/IIB string background and the first step is to recognize the compact/non-compact translationally invariant directions. Let us denote the Killing vector of one of them by \( (\partial/\partial y)^a \).

2. Boost the geometry in \( y \) direction by an amount \( \gamma \). It effectively is charging the initial solution by a momentum charge. However, if we start with an \( SO(1,1) \) symmetry, one can pair the Killing vector \( (\partial/\partial y)^a \) with the timelike one \( (\partial/\partial t)^a \) and thus, no additional charge is added. Then, this step appears to be trivial, i.e. diagonal, since the theory is boost-invariant.

3. Perform a T-duality along \( y \). This brings us to IIB/IIA supergravity solution for the background.

4. Generation of the twist can be conducted considering some additional \( S^1 \) or translational isometries. Let the one-form, associated with the additional isometry, is \( \sigma \). Then, we perform a twist by an amount of \( \alpha \)

\[
\sigma \rightarrow \sigma + 2\alpha dy.
\]

(2.5)

5. We now T-dualize the geometry back to IIA/IIB along \( y \). The twist followed by the T-duality is effectively a non-diagonal T-duality.
6. Boost along $y$ by $-\gamma$ to undo the initial boost.

7. For the decoupling we make a double-scaling limit keeping finite the ratio $\alpha e^\gamma$:

$$\beta = \frac{1}{2} \alpha e^\gamma = \text{fixed}. \quad (2.6)$$

The procedure, outlined above, is known also as null Melvin twist transformations. The steps [4] through [7] can be thought of as converting the string solution into a fluxbrane, followed by a boost and scaling to end up with a null isometry.

In addition to the discussion above, a large class of deformations can be found in [16,17]. A more general conclusion from there can be drown. Namely, the general form of large class of background solutions, obtained by null Melvin twists, have the form:

$$ds^2_{10} = -\frac{\Omega}{z^{2n}} du^2 + \frac{1}{z^2}(-2dvdu + dx_1^2 + dx_2^2 + dz^2) + ds^2_{X^5}, \quad (2.7)$$

$$F_{(5)} = (1 + *) \text{vol}_{X^5}, \quad (2.8)$$

$$B_{(2)} = \frac{1}{z^{2n}} P \wedge du, \quad (2.9)$$

where $X^5$ is an Einstein manifold and $P$ is one-form on $X^5$. In addition to the vector eigenfunction of the Laplacian on $X^5$, the generic background of this type includes also a B-field. Moreover, the factor $\Omega$ in the metric obeys an inhomogeneous scalar Laplace equation on $X^5$. We note that the analysis conducted in this paper for the particular case of $Schr_5 \times S^5$ background can be easily extended to these cases.

Actually, for $S^5$, this is the Hopf fibration $S^1 \to S^5 \to \mathbb{C}P^2$. Thus, $P$ is the 1-form potential for the Kähler form on $\mathbb{C}P^2$, and therefore $J^2_P = dP$.

Integrability, which plays a crucial role in proving holography, has been considered in some details in [19]. Concretely, consider $AdS_5 \times X^5$, where the metric on $X^5$ is $g_{\alpha\beta}$. Now we perform a null Melvin twist along a Killing vector $K$ on $X^5$. The result is

$$ds^2 = ds^2_{Schr_5} + ds^2_{X^5}, \quad (2.10)$$

where the Schrödinger part is given by

$$ds^2_{Schr_5} = -\frac{\Omega}{z^{2n}} du^2 + \frac{1}{z^4}(-2dvdu + dx_1^2 + dx_2^2 + dz^2), \quad \Omega = ||K||^2 = g_{\alpha\beta} K^\alpha K^\beta. \quad (2.11)$$

It is clear that $\Omega$ is non-negative being a square length of the Killing vector. The generated $B$-field has the form $(K_\alpha = g_{\alpha\beta} K^\beta)$:

$$B_{(2)} = \frac{1}{z^{2n}} K \wedge du. \quad (2.12)$$

An important remark is that in order to make holographic sense of these solutions, one has to impose some conditions. In order these to be holographic duals to non-relativistic field theories the light-cone coordinate $v$ should be periodic, $v \sim v + 2\pi r_v$ [20][22]. The momentum along this compact direction is quantized in units of the inverse radius $r_v^{-1}$. This momentum is interpreted as the Galilean mass (or the particle number) in the dual field theory. Note that the norm of the Killing vector $K$ may vanish on some locus in $X^5$, but still having a perfect gravity dual of non-relativistic theory [1]. In [19] the integrability has been discussed in the context of Bethe ansatz and certain properties, like spinning BNM solutions and their dispersion relations have been analyzed.

For particular examples, further discussions and procedures see also [23,24].

---

1This point is discussed, for instance in [23,24].
The case of $AdS_5 \times S^5$

Let us write the metric of the space-time as

$$ds^2 = ds^2_{AdS_5} + ds^2_{S^5}. \quad (2.13)$$

Here, the metric on $AdS_5$, in light-cone coordinates, is written by

$$ds^2_{AdS_5} = \ell^2 \frac{2dx^+dx^- + dx^idx_i + dz^2}{z^2}, \quad (2.14)$$

where $\ell$ is the AdS radius in the string frame. The metric of $S^5$ is useful to write as

$$ds^2_{S^5} = ds^2_{\mathbb{C}P^2} + (e^5)^2. \quad (2.15)$$

The two terms are the metric of the round $S^5$ in the form of Hopf fibration. We introduce the coordinate $\chi$ for the Hopf fibers, and use the local orthonormal frame

$$e^m \quad (m = 1, 2, 3, 4), \quad e^5 = d\chi + P. \quad (2.16)$$

Here $e^m$ are the vielbein in the base $\mathbb{C}P^2$ and $P$ is a differential on it

$$P = \frac{1}{2} \sin^2 \mu (d\alpha + \cos \theta d\phi). \quad (2.17)$$

Its exterior derivative is proportional to the Kähler form $I_{\mathbb{C}P^2}$ on $\mathbb{C}P^2$,

$$dP = -\frac{2}{r} I_{\mathbb{C}P^2} = -\frac{1}{r} I_{mn} e^m \wedge e^n = \frac{2}{r} (e^1 \wedge e^2 + e^3 \wedge e^4). \quad (2.18)$$

The final form for the metric becomes

$$ds^2 = \ell^2 \left( \frac{2dx^+dx^- + dx^idx_i + dz^2}{z^2} + (d\chi + P)^2 + ds^2_{\mathbb{C}P^2} \right). \quad (2.19)$$

The program we are going to follow is:

- Make a T-duality along $\chi$.
- Make a shift $x^- \rightarrow x^- + \tilde{\mu} \tilde{\chi}$, where $\tilde{\chi}$ is T-dualized $\chi$.
- Make T-duality back on $\tilde{\chi}$.

Following these rules one easily finds

$$ds^2 = \ell^2 \left( \frac{-\tilde{\mu}^2 (dx^+)^2}{z^4} + \frac{2dx^+d\tilde{x}^- + dx^idx_i + dz^2}{z^2} \right) + ds^2_{S^5}, \quad (2.20)$$

where the metric on the five-sphere is

$$\frac{ds^2_{S^5}}{\ell^2} = d\tilde{\chi}^2 + d\mu^2 + \frac{1}{4} \sin^2 \mu \left( d\alpha^2 + d\theta^2 + d\phi^2 \right) + \sin^2 \mu d\tilde{\chi} d\alpha + \sin^2 \mu \cos \theta d\tilde{\chi} d\phi + \frac{\sin^2 \mu \cos \theta}{2} d\alpha d\phi. \quad (2.21)$$
Furthermore, the deformed TsT background acquires non-zero $B$-field\(^2\)

\[\alpha' B^{(2)} = \frac{\ell^2 \hat{\mu}}{z^2} \wedge (d\hat{\chi} + P).\]  

To complete the discussion, we write the metric of the Schrödinger background and the $B$-field in global coordinates (for details see for instance \cite{18})

\[\frac{ds_{\text{Schr}}^2}{\ell^2} = - \left( \frac{\hat{\mu}^2}{Z^4} + 1 \right) dT^2 + \frac{2dT dV - \hat{X}^2 dT^2 + d\hat{X}^2 + dZ^2}{Z^2},\]  

\[\alpha' B^{(2)} = \frac{\ell^2 \hat{\mu}}{Z^2} \wedge (d\hat{\chi} + P), \quad \hat{\mu} = \frac{\ell^2}{\alpha' \hat{\mu}} = \frac{\sqrt{\lambda}}{2\pi} L.\]  

Here $\hat{x}^-$ and $\hat{\chi}$ are the dualized coordinates, $L$ is the shift parameter in the star product in (2.3). The relation between the original and dualized coordinates is

\[d\chi = d\hat{\chi} + \frac{\hat{\mu}}{z^2} dx^+, \quad dx^- = d\hat{x}^- - \hat{\mu} \left( d\hat{\chi} + \frac{\hat{\mu}}{z^2} + P \right).\]  

- The dual coordinates satisfy periodic boundary conditions.
- The original coordinates satisfy twisted boundary conditions:

\[x^-(2\pi) - x^-(0) = LJ,\]  

\[\chi(2\pi) - \chi(0) = 2\pi m - LP_- ,\]  

where $m \in \mathbb{Z}$ and $P_-$ is the charge associated with the null Melvin twist.

In the case of Schrödinger space times five sphere the twisted solution generated by TsT-transformations break supersymmetry completely \cite{17}. In what follows we will focus on the bosonic sector of the theory.

### 3 Pulsating strings in Schrödinger background

We start this section with an overview of the pulsating strings in the most supersymmetric example of AdS/CFT correspondence, namely $AdS_5 \times S^5$. Next we apply this construction to obtain pulsating string solutions in Schrödinger background.

#### 3.1 Pulsating strings in AdS/CFT correspondence

Let us briefly discuss pulsating strings in $AdS_5 \times S^5$ space. Pulsating strings were first introduced in \cite{29} and later on were generalized by \cite{30,32}. Since then there have been further examples of pulsating strings, both in AdS and non-AdS backgrounds \cite{33,46}. In this section we give a brief review on the pulsating string solution obtained in \cite{29}.

Let us consider a circular string, which pulsates on $S^5$ by expanding and contracting its length. In this case, the metric of $S^5$ and the relevant part of $AdS_5$ are given by

\[ds^2 = R^2 \left( \cos^2 \theta d\Omega_3^2 + d\theta^2 + \sin^2 \theta d\psi^2 + d\rho^2 - \cosh^2 \rho dt^2 \right),\]  

\(^2\)Note that in the original $AdS_5 \times S^5$ theory there is no $B$-field.
where \( R^2 = \alpha' \sqrt{\lambda} \) with \( \lambda \) the 't Hooft coupling. One can obtain the simplest pulsating string solution by identifying the target space time coordinate \( t \) with the worldsheet one, \( t = \tau \), and setting \( \psi = m\sigma \), which corresponds to a string stretched along \( \psi \) direction. We also set the ansatz for \( \theta = \theta(\tau) \) and \( \rho = \rho(\tau) \). Hence, the Nambu-Goto action reduces to

\[
S = -m\sqrt{\lambda} \int dt \sin^2 \theta \sqrt{\cosh^2 \rho - \dot{\rho}^2 - \dot{\theta}^2},
\]

(3.2)

where \( \dot{\theta} = d\theta/d\tau \). In order to obtain the solution and the string spectrum it is useful to pass to Hamiltonian formulation. For this purpose, after identifying the canonical momenta,

\[
\Pi_{\rho} = \frac{m\sqrt{\lambda} \sin \theta \rho}{\sqrt{\cosh^2 \rho - \dot{\rho}^2 - \dot{\theta}^2}}, \quad \Pi_{\theta} = \frac{m\sqrt{\lambda} \sin \theta \dot{\theta}}{\sqrt{\cosh^2 \rho - \dot{\rho}^2 - \dot{\theta}^2}},
\]

(3.3)

we can write the Hamiltonian in the form \([29]\):

\[
H = \cosh \rho \sqrt{\Pi_{\rho}^2 + \Pi_{\theta}^2 + m^2 \lambda \sin^2 \theta}.
\]

(3.4)

If the string is placed at the origin (\( \rho = 0 \)) of \( AdS_5 \) space, we see that the squared Hamiltonian have a form similar to a point particle. Here, the last term in (3.4) can be considered as a perturbation. Therefore one can first find the wave function for a free particle in the above geometry

\[
\cosh \rho \frac{d}{d\rho} \left( \cosh \rho \sin^3 \rho \frac{d}{d\rho} \psi(\rho, \theta) \right) - \cosh \rho \frac{d}{\sin \theta \cos^3 \theta d\theta} \left( \sin \theta \cos^3 \theta \frac{d}{d\theta} \psi(\rho, \theta) \right) = E^2 \psi(\rho, \theta).
\]

(3.5)

Standard separation of variables, \( \psi(\rho, \theta) = f(\rho) g(\theta) \), leads to two decoupled ordinary differential equations, namely an equation for \( g(\theta) \)

\[
\frac{1}{g(\theta) \sin \theta \cos^3 \theta} \frac{d}{d\theta} \left( \sin \theta \cos^3 \theta \frac{d}{d\theta} g(\theta) \right) = \alpha,
\]

(3.6)

where \( \alpha \) is the separation constant, and an equation for \( f(\rho) \)

\[
\frac{\cosh \rho}{\sinh^2 \rho d(\cosh \rho)} \left( \cosh \rho \sinh^4 \rho \frac{d}{d(\cosh \rho)} f(\rho) \right) + \alpha \cosh ^2 \rho f(\rho) + E^2 f(\rho) = 0.
\]

(3.7)

Equation (3.6) reduces to

\[
g''(\theta) + (\cot \theta - 3 \tan \theta) g'(\theta) - \alpha g(\theta) = 0.
\]

(3.8)

Its regular solution is proportional to a hypergeometric function,

\[
g(\theta) = \, _2F_1 \left( 1 - \frac{\sqrt{4 - \alpha}}{2}, \frac{1}{2}(\sqrt{4 - \alpha} + 2), 2, \cos^2 \theta \right),
\]

(3.9)

which reduces to a polynomial if its series is truncated at some finite integer order \( n \). This can be achieved if we set its first argument to be equal to \(-n\), thus we find the separation constant \( \alpha \):

\[
\alpha = -4n(n + 2).
\]

(3.10)
Taking advantage of the relation between the hypergeometric function and the Jacobi polynomials, namely

\[ _2F_1(-n, \tilde{\alpha} + \tilde{\beta} + 1 + n, \tilde{\alpha} + 1, z) = \frac{n!}{(\tilde{\alpha} + 1)_n} P_n^{(\tilde{\alpha}, \tilde{\beta})}(1 - 2z), \tag{3.11} \]

where, in our case \( \tilde{\alpha} = 1, \tilde{\beta} = 0 \) and \( z = \cos \theta \). We can further transform the Jacobi polynomial to the standard spherical harmonics \( P_{2n}(\cos \theta) \), i.e. \( P_m^{(1,0)}(1 - 2z) = c P_{2n}(z) \) \[17\], where \( m = 2n \) should be even. Thus the final polynomial solution of Eq. (3.6) up to a normalization constant is

\[ g(\theta) = P_{2n}(\cos \theta). \tag{3.12} \]

Let us take a look at the second equation (3.7). Changing the variable \( \rho \) to \( x = \cosh \rho > 0 \), one finds

\[ x^2 (x^2 - 1) f''(x) + (5x^2 - 1) x f'(x) + (\alpha x^2 + E^2) f(x) = 0. \tag{3.13} \]

We can look for simple polynomial solution of type \( f(x) = c x^a \), where \( a \) is some constant. This leads to

\[ c x^a (x^2 (a^2 + 4a + \alpha) - a^2 + E^2) = 0, \tag{3.14} \]

which is satisfied only if

\[ a^2 + 4a = -\alpha, \quad E^2 - a^2 = 0. \tag{3.15} \]

Substituting \( \alpha \) from equation (3.10) one finds \( a = -2n - 4 \) and the full solution to Eq. (3.5) becomes

\[ \Psi_{2n}(\rho, \theta) = (\cosh \rho)^{-2n-4} P_{2n}(\cos \theta). \tag{3.16} \]

Now, the energy levels are given by

\[ E = \Delta = 2n + 4. \tag{3.17} \]

As we mentioned in the Introduction, strings in Schrödinger background is conjectured to have as a holographic dual strongly coupled non-relativistic conformal theory. According to holographic dictionary the energy on string side should correspond to the (anomalous) dimension of certain operator on field theory side. Thus, (3.17) is interpreted as the bare dimension of the field theory operator. The weak coupling on string theory side allows to expand (3.4) in \( \lambda \) and obtain the first quantum corrections. For highly excited states (large energies), one should take large \( n \), so we can approximate the spherical harmonics as

\[ P_{2n}(\cos \theta) \approx \sqrt{\frac{4}{\pi}} \cos(2n\theta). \tag{3.18} \]

The first order correction to the energy in perturbation theory now yields

\[ \delta E^2 = \frac{\pi^2}{2} \int_0^\pi d\theta \Psi_{2n}^*(0, \theta) m^2 \lambda \sin^2 \theta \Psi_{2n}(\theta) = \frac{m^2 \lambda}{2}. \tag{3.19} \]

Finally, the corrected energy levels yield

\[ E = \sqrt{(2n + 4)^2 + \frac{m^2 \lambda}{2}}. \tag{3.20} \]
Therefore, one can calculate the anomalous dimension of the corresponding YM operators\footnote{See \cite{29} for more details.}

\[(\Delta - 4)^2 = 4n^2 + \delta E^2,\]  

or up to first order in $\lambda$:

\[\Delta - 4 = 2n \left( 1 + \frac{m^2 \lambda}{2 (2n)^2} \right). \tag{3.22}\]

On should note that in this case the $R$-charge is zero. One can include it by considering a pulsating string on $S^5$, which center of mass is moving on the $S^3$ subspace of $S^5 \ \cite{49}$. While, in the previous example, $S^3$ part of the metric was assumed trivial, now we consider all the $S^3$ angles to depend on $\tau$ (only). The corresponding Nambu-Goto action is then given by

\[S = -m\sqrt{\lambda} \int dt \sin \theta \sqrt{1 - \dot{\theta}^2 - \cos^2 \theta g_{ij} \dot{\phi}^i \dot{\phi}^j}, \tag{3.23}\]

where $\phi_i$ are $S^3$ angles and $g_{ij}$ is the corresponding $S^3$ metric. In this case the Hamiltonian is written by $\cite{49}$

\[H = \sqrt{\Pi^2 \theta + g_{ij} \Pi_i \Pi_j + m^2 \lambda \sin^2 \theta}, \tag{3.24}\]

where again the squared Hamiltonian looks like the point particle one. However, now the potential has angular dependence. Denoting the quantum number of $S^3$ and $S^5$ by $J$ and $L$ correspondingly, one can write the Schrödinger equation in the form

\[-\frac{4}{\omega} \frac{d}{d\omega} \Psi(\omega) + \frac{J(J + 1)}{\omega} \Psi(\omega) = L(L + 4) \Psi(\omega), \tag{3.25}\]

with $\omega = \cos^2 \theta$. The explicit solution is

\[\Psi(\omega) = \sqrt{\frac{2(l + 1)}{(l - j)!}} \frac{1}{\omega} \left( \frac{d}{d\omega} \right)^{l-j} \omega^{l+j}(1 - \omega)^{l-j}, \quad j = \frac{J}{2}, \quad l = \frac{L}{2}. \tag{3.26}\]

The first order correction to the squared energy $\delta E^2$ in this case yields

\[\delta E^2 = m^2 \lambda \frac{2(l + 1)^2 - (j + 1)^2 - j^2}{(2l + 1)(2l + 3)}. \tag{3.27}\]

Now, the corrected energy (up to first order in $\lambda$) can be written in the form

\[E = \sqrt{L(L + 4)} + \frac{m^2 \lambda (L - J)(J + L)}{4L^2 \sqrt{L(L + 4)}} + \mathcal{O}(\lambda^3). \tag{3.28}\]

Finally, the anomalous dimension can also be calculated

\[\gamma = \frac{m^2 \lambda}{4L} \alpha(2 - \alpha), \tag{3.29}\]

with $\alpha = 1 - J/L$. 

\[\]
3.2 Pulsating string solutions in Schrödinger background

Now, we are in a position to obtain pulsating string solutions in Schrödinger background. To this end we will construct the Polyakov action and find appropriate solutions. To start with, we write the line element of Schrödinger geometry in global coordinates

\[
\frac{ds^2_{\text{Schr}}}{\ell^2} = - \left( 1 + \frac{\mu^2}{Z^4} + \frac{X^2}{Z^2} \right) dT^2 + \frac{2dTdV + dX^2 + dZ^2}{Z^2},
\]

and

\[
\frac{ds^2_\varepsilon}{\ell^2} = d\chi^2 + d\mu^2 + \frac{1}{4} \sin^2 \mu \left( d\alpha^2 + d\theta^2 + d\phi^2 \right) + \sin^2 \mu d\chi d\alpha + \sin^2 \mu \cos \theta d\chi d\phi + \frac{\sin^2 \mu \cos \theta}{2} d\alpha d\phi,
\]

where we have redefine \( \hat{\chi} \rightarrow \chi \) for simplicity, as opposed to Eq. (2.21). Due to the \( T \)T transformation the theory acquires also a \( B \)

\[
B_{(2)} = \frac{\ell^2 \mu}{\alpha' Z^2} dT \wedge \left( d\chi + \frac{\sin^2 \mu}{2} d\alpha + \frac{\sin^2 \mu \cos \theta}{2} d\phi \right).
\]

Hence, the Polyakov string action in conformal gauge \((\alpha, \beta = 0, 1 \text{ and } M, N = 0, \ldots, 9)\) is given by

\[
S = -\frac{1}{4\pi \alpha'} \int d\tau d\sigma \left\{ \sqrt{-h} h^{\alpha \beta} \partial_\alpha X^M \partial_\beta X^N G_{MN} - \epsilon^{\alpha \beta} \partial_\alpha X^M \partial_\beta X^N B_{MN} \right\},
\]

where \( h^{\alpha \beta} = \text{diag}(-1, 1) \) and \( \epsilon^{01} = -\epsilon^{10} = 1 \). The explicit form of the Lagrangian, with respect to the metric and the \( B \)-field, yields

\[
-4\pi \alpha' \mathcal{L} = G_{TT}(T'^2 - T^2) + G_{\tilde{X}\tilde{X}}(\tilde{X}'^2 - \tilde{X}^2) + G_{ZZ}(Z'^2 - Z^2) + 2G_{TV}(T'V' - TV) + G_{\chi\chi}(\chi'^2 - \chi^2) + G_{\mu\mu}(\mu'^2 - \mu^2) + G_{\theta\theta}(\theta'^2 - \theta^2) + G_{\alpha\alpha}(\alpha'^2 - \alpha^2) + G_{\phi\phi}(\phi'^2 - \phi^2) + 2G_{\chi\phi}(\chi'\phi' - \chi\phi) + 2G_{\chi\phi}(\chi'\phi' - \chi\phi) + 2B_{T\chi}(T\tilde{X} - T\tilde{X}') + 2B_{T\alpha}(T\tilde{X} - T\tilde{X}') + 2B_{T\phi}(T\tilde{\phi} - T\tilde{\phi}').
\]

Beside the equations of motion (EoM) the solutions should also satisfy the Virasoro constraints

\[
\text{Vir}_1 : \quad G_{MN} \left( \dot{X}^M \dot{X}^N + X''^M X^N \right) = 0, 
\]

\[
\text{Vir}_2 : \quad G_{MN} \dot{X}^M X^N = 0.
\]

To find the general solution of the set of EoMs, satisfying (3.35) and (3.36), is quite nontrivial task. To obtain pulsating string solutions in Schrödinger background we need an appropriate ansatz for circular string configurations,

\[
T = \kappa \tau, \kappa > 0, \quad Z = \text{const} \neq 0, \quad \tilde{X} = 0, \quad V = 0,
\]

\[
\mu = \mu(\tau), \quad \theta = \theta(\tau), \quad \chi = n^1 \sigma, \quad \alpha = n^2 \sigma, \quad \phi = n^3 \sigma.
\]
A quick check shows that the second Virasoro constraint is trivially satisfied, whereas the first one gives rise to the following nontrivial equation:

$$\ddot{\mu} + \frac{1}{4} \sin^2 \mu \left( \dot{\theta}^2 + (n^2)^2 + (n^3)^2 + 4n^1(n^2 + n^3 \cos \theta) + 2n^2n^3 \cos \theta \right) - \left( 1 + \frac{\dot{\mu}^2}{Z^2} \right) \kappa^2 + (n^1)^2 = 0. \quad (3.38)$$

The substitution of the ansatz (3.37) into the equations for $V, \vec{X}, \chi, \alpha$ and $\phi$, shows that they are trivially satisfied. The other equations, namely for $T, Z, \theta$ and $\mu$, require further analysis. Let us list the relevant equations. The EoM for $T$ results in

$$\frac{d}{d\tau} \left[ \sin^2 \mu \left( n^2 + n^3 \cos \theta \right) \right] = 0 \quad \Rightarrow \quad \sin^2 \mu \left( n^2 + n^3 \cos \theta \right) = A = \text{const.} \quad (3.39)$$

We refer to this equation as the pulsating condition. For $Z$ we have the solution

$$Z^2 = \frac{2\dot{\mu} \alpha' \kappa}{2n^1 + A}, \quad (3.40)$$

which shows that $Z$ is a constant, as it should be, due to the ansatz (3.37). The equation for $\theta$ becomes

$$\frac{d}{d\tau} \left( \sin^2 \mu \dot{\theta} \right) - n^3 \sin^2 \mu \sin \theta \left( 2n^1 + n^2 - \frac{2\dot{\mu} \kappa}{\alpha' Z^2} \right) = 0. \quad (3.41)$$

Finally, for $\mu$ we have

$$\ddot{\mu} + \frac{1}{4} \sin \mu \cos \mu \left( (n^2)^2 + (n^3)^2 - \dot{\theta}^2 + 2n^2n^3 \cos \theta + 4 \left( n^1 - \frac{\dot{\mu} \kappa}{\alpha' Z^2} \right) \left( n^2 + n^3 \cos \theta \right) \right) = 0. \quad (3.42)$$

Obviously $n^1$ and $A$ can not be zero at the same time, due to (3.40), thus $2n^1 + A \neq 0$. This suggests the following cases:

(i) $n^1 \neq 0, \quad A \neq 0,$ \quad (3.43)

(ii) $n^1 = 0, \quad A \neq 0,$ \quad (3.44)

(iii) $n^1 \neq 0, \quad A = 0,$ \quad such as \quad $n^2 + n^3 \cos \theta = 0,$ \quad or \quad $n^2 = n^3 = 0.$ \quad (3.45)

Let us focus on the first case (i). The substitution of the pulsating condition (3.39),

$$\sin^2 \mu = \frac{A}{n^2 + n^3 \cos \theta}, \quad (3.46)$$

into the $\theta$ equation, results in the following relation

$$\frac{d}{d\tau} \left( \frac{\dot{\theta}}{n^2 + n^3 \cos \theta} \right) - n^3 K \frac{\sin \theta}{n^2 + n^3 \cos \theta} = 0, \quad (3.47)$$

where $K = 2n^1 + n^2 - \frac{2\dot{\mu} \kappa}{\alpha' Z^2}$. Multiplying Eq. (3.47) by $\frac{\dot{\theta}}{n^2 + n^3 \cos \theta}$, one finds

$$\frac{d}{d\tau} \left[ \frac{1}{2} \left( \frac{\dot{\theta}}{n^2 + n^3 \cos \theta} \right)^2 \right] - \frac{d}{d\tau} \left( \frac{K}{n^2 + n^3 \cos \theta} \right) = 0. \quad (3.48)$$
Integrating once we end up with an equation for the only variable needed for a complete pulsating string solution:

\[
\frac{1}{2} \left( \frac{\dot{\theta}}{n^2 + n^3 \cos \theta} \right)^2 - \frac{K}{n^2 + n^3 \cos \theta} = C = \text{const.} \tag{3.49}
\]

We can rewrite the latter equation such as

\[
\dot{\theta}^2 = 2(n^2 + n^3 \cos \theta) \left( C(n^2 + n^3 \cos \theta) + K \right). \tag{3.50}
\]

Multiplying Eq. (3.50) by \(\sin^2 \theta\), we find

\[
\left( \frac{d}{d\tau} \cos \theta \right)^2 = 2(1 - \cos^2 \theta)(n^2 + n^3 \cos \theta)(Cn^3 \cos \theta + Cn^2 + K). \tag{3.51}
\]

At this point, it is convenient to introduce a new variable \(u = \cos \theta, |u| \leq 1\). Thus, equation (3.51) becomes

\[
\left( \frac{d}{d\tau} u \right)^2 = 2 \left(1 - u^2 \right) P_2(u), \tag{3.52}
\]

where

\[
P_2(u) = C(n^3)^2 u^2 + n^3 (2Cn^2 + K) u + n^2 (Cn^2 + K). \tag{3.53}
\]

Due to (3.52), the following condition should hold \(P_2(u) \geq 0, \forall u \in [-1, 1]\). Since the discriminant of the polynomial \(P_2(u)\) is non-negative, \(D = K^2 (n^3)^2 \geq 0\), there are two real roots,

\[
u_{1,2} = \frac{1}{2Cn^3} \left(-2Cn^2 - K \pm K \right) = \left\{ \begin{array}{ll} \frac{-n^2}{n^2}, \\ - \left( \frac{n^2}{n^2} + \frac{K}{Cn^3} \right) \end{array} \right\}. \tag{3.54}
\]

Note that the first case coincides with the case \(K = 0\). Now, equation (3.52) takes the form

\[
\left( \frac{d}{d\tau} u \right)^2 = 2 C \left(n^3\right)^2 \left(1 - u^2 \right) (u - u_1) (u - u_2) \geq 0. \tag{3.55}
\]

The range of \(u_1\) and \(u_2\) can be arbitrary. It is clear that the solutions essentially depend on the signs of \(C, u_1, u_2\) and that of \(u\) between \([-1, 1]\). Therefore, the problem of finding periodic solutions is brought to several cases, which should be analyzed separately. For example, for \(C > 0\) and \(K > 0\), the following orders are possible:

\[
u_1 < u_2 < -1 \leq u(\tau) \leq 1, \tag{3.56a}
\]

\[
u_1 < -1 < u_2 \leq u(\tau) \leq 1, \tag{3.56b}
\]

\[-1 < u_1 < u_2 \leq u(\tau) \leq 1, \tag{3.56c}
\]

\[-1 \leq u(\tau) \leq u_1 < u_2 < 1, \tag{3.56d}
\]

\[-1 \leq u(\tau) \leq u_1 < 1 < u_2, \tag{3.56e}
\]

\[-1 \leq u(\tau) \leq 1 < u_1 < u_2. \tag{3.56f}
\]

\(^4\text{Note that the integers } n^i \text{ could be positive or negative. On the other hand we have the constraint } -1 \leq u \leq 1 \text{ since } u = \cos \theta. \text{ If one of the roots is outside of this interval, due to (3.52), there are no real solutions to this equation. The case when both roots are outside the interval is discussed below.}\)
In the case of $C < 0$ and $K > 0$, one has the following options:

\begin{align}
  u_1 < -1 & \leq u(\tau) \leq u_2 < 1, \tag{3.57a} \\
  u_1 < -1 & \leq u(\tau) \leq 1 < u_2, \tag{3.57b} \\
  -1 < u_1 & \leq u(\tau) \leq u_2 < 1, \tag{3.57c} \\
  -1 < u_1 & \leq u(\tau) \leq 1 < u_2. \tag{3.57d}
\end{align}

Finally, it is also possible that $K = 0$, and $C > 0$. In this case

$$P_2(u) = C \left(n^3\right)^2 u^2 + 2Cn^2u + C \left(n^2\right)^2 \geq 0 \tag{3.58}$$

The discriminant is zero, thus $u_1 = u_2 = -n^2/n^3$ and Eq. (3.52) takes the form

$$\left(\frac{d}{d\tau} u\right)^2 = 2C \left(n^3\right)^2 (1 - u^2) (u - u_1)^2 \geq 0. \tag{3.59}$$

We start our analysis with $C > 0$, $K > 0$ and $u_1 < u_2 < -1 \leq u(\tau) \leq 1$. Then, we integrate the equation (3.55):

$$\int_{u(\tau)}^{1} \frac{du}{\sqrt{(1-u)(u-(-1))(u-u_2)(u-u_1)}} = \sqrt{2C \left(n^3\right)^2} \int_0^\tau d\tau = \sqrt{2C \left(n^3\right)^2} \tau. \tag{3.60}$$

This integral can be found in Gradshteyn and Ryzhik [50], which is an integral of the type

$$\int_{b}^{u} \frac{dz}{\sqrt{(a-z)(z-b)(z-c)(z-d)}}, \quad a \geq u \geq b > c > d. \tag{3.61}$$

This integral can be solved in terms of a first kind elliptic integral:

$$\int_{b}^{u} \frac{dz}{\sqrt{(a-z)(z-b)(z-c)(z-d)}} = \frac{2}{\sqrt{(a-c)(b-d)}} F(\xi, r), \tag{3.62}$$

where

$$\xi = \arcsin \sqrt{(b-d)(a-u)} \quad \text{and} \quad r = \sqrt{(a-b)(c-d)} \tag{3.63}$$

Therefore, in view of (3.60), we have

$$F(\xi, r) = \sqrt{2^{-1}C \left(n^3\right)^2(a-c)(b-d)} \tau, \tag{3.64}$$

where $a = 1$, $b = -1$, $c = u_2 = -|u_2|$, $d = u_1 = -|u_1|$. In other words, one finds

$$\sin \xi = sn \left(\sqrt{2^{-1}C \left(n^3\right)^2(a-c)(b-d)} \tau, r\right), \tag{3.65}$$

or explicitly

$$\frac{(b-d)(a-u)}{(a-b)(u-d)} = sn^2 \left(\sqrt{2^{-1}C \left(n^3\right)^2(a-c)(b-d)} \tau, r\right). \tag{3.66}$$
The solution of this equation for \( u(\tau) \) is given by

\[
\begin{align*}
\frac{u(\tau)}{1} &= \frac{1 - \frac{2|u_1|}{|u_1| - 1} \text{sn}^2 \left( \sqrt{2^{-1}C(n^3)^2(|u_1| - 1)(1 + |u_2|)} \tau, r \right)}{1 + \frac{2}{|u_1| - 1} \text{sn}^2 \left( \sqrt{2^{-1}C(n^3)^2(|u_1| - 1)(1 + |u_2|)} \tau, r \right)}.
\end{align*}
\]

(3.67)

Returning to the original variable the final solution yields

\[
\theta(\tau) = \arccos \left( \frac{1 - \frac{2|u_1|}{|u_1| - 1} \text{sn}^2 \left( \sqrt{2^{-1}C(n^3)^2(|u_1| - 1)(1 + |u_2|)} \tau, r \right)}{1 + \frac{2}{|u_1| - 1} \text{sn}^2 \left( \sqrt{2^{-1}C(n^3)^2(|u_1| - 1)(1 + |u_2|)} \tau, r \right)} \right).
\]

(3.68)

We list the solutions for the other cases from (i), (ii) and (iii) in appendix C.

4 Energy corrections and anomalous dimensions

To proceed with the energy corrections we need the Nambu-Goto string action. The first step towards finding the Nambu-Goto action is to make a pullback of the line element of the metric of \( S\text{chr}_5 \times S^5 \) to the subspace, where string dynamics takes place. The result for the metric is

\[
ds^2 = \ell^2 \left(-|G_{00}|dT^2 + \sum_{i,j=1}^2 G_{ij}(\mu, \theta)dx^i dx^j + \sum_{k,h=1}^3 \hat{G}_{kh}(\mu, \theta)dy^k dy^h \right),
\]

where for brevity we used the notations

\[
|G_{00}| = 1 + \frac{\hat{\mu}^2}{Z^4}, \quad (G_{ij}) = \begin{pmatrix}
1 & 0 & 0 \\
0 & \sin^2 \mu & 0 \\
0 & 0 & \frac{4}{\sin^2 \mu}
\end{pmatrix}, \quad (G_{ij}) = \begin{pmatrix}
1 & 0 & 0 \\
0 & \sin^2 \mu & 0 \\
0 & 0 & \frac{4}{\sin^2 \mu}
\end{pmatrix}, \quad (4.1)
\]

and

\[
\left( \hat{G}_{kh} \right) = \begin{pmatrix}
1 & \sin^2 \mu & \sin^2 \mu \cos \theta \\
\sin^2 \mu & 2 & 2 \sin^2 \mu \cos \theta \\
\sin^2 \mu & 2 \sin^2 \mu \cos \theta & 4 \sin^2 \mu \cos \theta
\end{pmatrix}.
\]

(4.2)

In contrast to the case from the previous subsection, the T\(s\)T transformation generates a \( B \)-field, involving time direction:

\[
B_{(2)} = \ell^2 \frac{\hat{\mu}}{\alpha' Z^2} dT \wedge \left( d\chi + \frac{\sin^2 \mu}{2} d\alpha + \frac{\sin^2 \mu \cos \theta}{2} d\phi \right) = \ell^2 \sum_{k=1}^3 b_{0k}(\mu, \theta) dT \wedge dy^k,
\]

where

\[
b_{01} = \frac{\hat{\mu}}{\alpha' Z^2}, \quad b_{02} = \frac{\hat{\mu}}{2\alpha' Z^2} \sin^2 \mu, \quad b_{03} = \frac{\hat{\mu}}{2\alpha' Z^2} \sin^2 \mu \cos \theta.
\]

(4.3)
The induced worldsheet metric and the $B$-field components become

\[
\frac{ds_{\text{us}}^2}{\ell^2} = \left( -|G_{00}| \kappa^2 + \sum_{i,j=1}^{2} G_{ij}(\mu, \theta) \dot{x}^i \dot{x}^j \right) d\tau^2 + \left( \sum_{k,h=1}^{3} \hat{G}_{kh}(\mu, \theta) n^k n^h \right) d\sigma^2, \tag{4.6a}
\]

\[
B^{\text{us}}_{(2)} = 2\ell^2 B_{\tau \sigma} \, d\tau \wedge d\sigma, \quad B_{\tau \sigma}(\mu, \theta) = -B_{\sigma \tau} = \frac{1}{2} \sum_{k=1}^{3} b_{0k}(\mu, \theta) \kappa n^k. \tag{4.6b}
\]

With these preparations at hand we can write the Nambu-Goto action,

\[
S_{\text{NG}} = -\frac{1}{2 \pi \alpha'} \int d\tau d\sigma \sqrt{-\det \left( G_{\mu \nu} \partial_{\alpha} X^\mu \partial_{\beta} X^\nu - B_{\mu \nu} \partial_{\alpha} X^\mu \partial_{\beta} X^\nu \right)}, \tag{4.7}
\]

or in terms of the notations we introduced above:

\[
S_{\text{NG}}^{\text{puls}} = \frac{\ell^2}{\alpha'} \int d\tau \sqrt{\left( \sum_{k,h=1}^{3} \hat{G}_{kh}(\mu, \theta) n^k n^h \right) \left( |G_{00}| \kappa^2 - \sum_{i,j=1}^{2} G_{ij}(\mu, \theta) \dot{x}^i \dot{x}^j \right) - B^2_{\tau \sigma}(\mu, \theta)}, \tag{4.8}
\]

where $\frac{\ell^2}{\alpha'} = \sqrt{\lambda}$ is the 't Hooft coupling constant.

To obtain the energy correction we consider the Hamiltonian formulation of the problem. For the case under consideration the canonical momenta are given by

\[
\Pi_k = \frac{\partial L}{\partial \dot{x}^k} = \frac{\sqrt{\lambda} \left( \sum_{k,h=1}^{3} \hat{G}_{kh} n^k n^h \right) \sum_{i=1}^{2} G_{ki} \dot{x}^i}{\left( \sum_{k,h=1}^{3} \hat{G}_{kh} n^k n^h \right) \left( |G_{00}| \kappa^2 - \sum_{i,j=1}^{2} G_{ij}(\mu, \theta) \dot{x}^i \dot{x}^j \right) - B^2_{\tau \sigma}}, \quad k = 1, 2. \tag{4.9}
\]

Solving for the derivatives in terms of the canonical momenta and substituting back into the Legendre transformed Lagrangian, $L = \Pi_k \dot{x}^k - H$, we find the (square of) the Hamiltonian:

\[
H_{\text{puls}}^2 = \frac{|\vec{r}|^2 |G_{00}| \kappa^2 - B^2_{\tau \sigma}}{|\vec{r}|^2} \sum_{i,j=1}^{2} G^{ij} \Pi_i \Pi_j + \lambda \left( |\vec{r}|^2 |G_{00}| \kappa^2 - B^2_{\tau \sigma} \right), \tag{4.10}
\]

where $|\vec{r}|^2$ is defined in Eq. (4.12). As in other cases of pulsating strings in holography, we observe that $H^2$ looks like a point-particle Hamiltonian, in which the last term serves as a potential

\[
U(\mu, \theta) = \left( \sum_{k,h=1}^{3} \hat{G}_{kh}(\mu, \theta) n^k n^h \right) |G_{00}| \kappa^2 - B^2_{\tau \sigma}(\mu, \theta). \tag{4.11}
\]

The steps we will follow involve a perturbative expansion in the small coupling constant $\lambda$. The semiclassical quantization of the pulsating string then ends up with the corrections to the energy. According to the AdS/CFT dictionary, the anomalous dimension of the corresponding SYM operators are directly related to the corrections to the energy.

For brevity of the notations it is useful to make some definitions. First, we define the following ”scalar product”:

\[
|\vec{r}|^2 := \sum_{k,h=1}^{3} \hat{G}_{kh} n^k n^h = \frac{1}{4} (a_1 + a_2 \sin^2 \mu) > 0, \tag{4.12}
\]
where the constants $a_1$ and $a_2$ are written by
\[ a_1 = 4(n^1)^2 + 2(2n^1 + n^2)A, \quad a_2 = (n^3)^2 - (n^2)^2. \] (4.13)

Here, $A = (n^2 + n^3 \cos \theta) \sin^2 \mu = \text{const.}$, is the familiar pulsating condition from Eq. (3.39). Analogously, we find
\[ B_{r\sigma}^2 = \frac{\kappa^2 b^2}{4}, \quad b^2 = \frac{\hat{m}^2}{4 \alpha^2 Z^2} (A + 2n^1)^2 = \frac{(A + 2n^1)^4}{4 \alpha^2 \kappa^2}, \] (4.14)

where $A$ is the defining constant in the pulsating condition (3.39), $\hat{m}$ is defined in Eq. (2.24), and $Z$ is defined in Eq. (3.40). Hence, one has
\[ |G_{00}| \kappa^2 \|\vec{n}\|^2 - B_{r\sigma}^2 = \frac{\kappa^2}{4} (a_1 |G_{00}| - b^2 + a_2 |G_{00}| \sin^2 \mu) = \frac{\kappa^2}{4} (A_1 + A_2 \sin^2 \mu), \] (4.15)

with
\[ A_1 = a_1 |G_{00}| - b^2, \quad A_2 = a_2 |G_{00}| \] (4.16)

The kinetic term of the Hamiltonian (4.10) is considered as a two dimensional Laplace-Beltrami operator
\[ \sum_{i,j=1}^2 G^{ij}(\mu, \theta) \Pi_i \Pi_j \rightarrow \triangle^{(2)} = \frac{1}{\sqrt{\det(G_{ij})}} \Delta (G^{ij}) \frac{1}{\sqrt{\det(G_{ij})}}. \] (4.17)

In our case, this operator takes the form
\[ \triangle^{(2)} = \frac{1}{\sin \mu} \frac{\partial}{\partial \mu} \left( \sin \mu \frac{\partial}{\partial \mu} \right) + \frac{4}{\sin^2 \mu} \frac{\partial^2}{\partial \theta^2}. \] (4.18)

This Laplace-Beltrami operator defines the eigen-functions of the Hamiltonian. Collecting the results and using the above notations the Schrödinger equation for the wave function becomes
\[ \frac{|G_{00}| \kappa^2 \|\vec{n}\|^2 - B_{r\sigma}^2}{\|\vec{n}\|^2} \triangle^{(2)} \Psi(\mu, \theta) = -E^2 \Psi(\mu, \theta), \] (4.19)

or explicitly
\[ \left( \frac{1}{\sin \mu} \frac{\partial}{\partial \mu} \left( \sin \mu \frac{\partial}{\partial \mu} \right) + \frac{4}{\sin^2 \mu} \frac{\partial^2}{\partial \theta^2} \right) \Psi(\mu, \theta) = -\frac{E^2}{\kappa^2} \frac{(a_1 + a_2 \sin^2 \mu)}{(A_1 + A_2 \sin^2 \mu)} \Psi(\mu, \theta). \] (4.20)

Now, we make the standard separation of the variables
\[ \Psi(\mu, \theta) = \Psi(\mu) e^{il\theta}, \quad l \in \mathbb{Z}. \] (4.21)

The equation for $\Psi(\mu)$ yields
\[ \left( \frac{1}{\sin \mu} \frac{d}{d\mu} \left( \sin \mu \frac{d}{d\mu} \right) - \frac{4l^2}{\sin^2 \mu} \right) \Psi(\mu) = -\frac{E^2}{\kappa^2} \frac{(a_1 + a_2 \sin^2 \mu)}{(A_1 + A_2 \sin^2 \mu)} \Psi(\mu). \] (4.22)

To bring Eq. (4.22), into more familiar from, we introduce a new variable $z = \cos \mu$, where $0 \leq z \leq 1$ and $0 \leq \mu \leq \pi/2$. Thus, one can rewrite the above equation as
\[ \left( 1 - z^2 \right) \frac{d^2}{dz^2} - 2z \frac{d}{dz} - \frac{4l^2}{\sin^2 \mu} + \frac{E^2}{\kappa^2} \frac{(a_1 + a_2 (1 - z^2))}{(A_1 + A_2 (1 - z^2))} \right) \Psi(z) = 0. \] (4.23)
The latter is a second order ordinary differential equation of the form

\[ \Psi''(z) + \bar{P}(z) \Psi'(z) + \bar{Q}(z) \Psi(z) = 0, \]  

(4.24)

where

\[ \bar{P}(z) = -\frac{2z}{1-z^2}, \quad \bar{Q}(z) = -\frac{1}{1-z^2} \left( \frac{4z^2}{1-z^2} - \frac{E^2 (a_1 + a_2 (1-z^2))}{\kappa^2 |G_{00}| (a_1 + a_2 (1-z^2) - b^2)} \right). \]  

(4.25)

In general, this is a Heun type equation,

\[ H''(z) + P(z) H'(z) + Q(z) H(z) = 0, \]  

(4.26)

with coefficients

\[ P(z) = \left( \frac{\gamma + \frac{\delta}{z - 1} + \frac{\varepsilon}{z - a}}{z - a} \right), \quad Q(z) = \frac{\alpha \beta - q}{z(z - 1)(z - a)}, \]  

(4.27)

where \( \varepsilon = \alpha + \beta + 1 - \gamma - \delta \). Now, we want to map our equation to Heun's one. In order to find the corresponding parameters \( q, \alpha, \beta, \gamma, \delta \), we make the identification \( P(z) = \bar{P}(z) \) and \( Q(z) = \bar{Q}(z) \). After equating the coefficients in front of the powers of \( z \), one finds the following algebraic system:

\[
\begin{align*}
 a\gamma &= 0, \\
 1 - \alpha - \beta &= 0, \\
 a_2 |G_{00}| \kappa^2 q &= 0, \\
 a(\gamma + \delta - 2) - \delta &= 0, \\
 (a - 1)\delta + \alpha + \beta + 1 &= 0, \\
 (E^2 + \alpha \beta |G_{00}| \kappa^2) a_2 &= 0, \\
 (b^2 - (a_1 + a_2) |G_{00}|) \kappa^2 q &= 0, \\
 (b^2 - (a_1 + 2a_2) |G_{00}|) \kappa^2 q &= 0, \\
 4a_2 |G_{00}| \kappa^2 t^2 - (a_1 + 2a_2) E^2 + (b^2 - (a_1 + 2a_2) |G_{00}|) \kappa^2 \alpha \beta &= 0, \\
 ((a_1 + a_2) |G_{00}| - 4b^2) \kappa^2 t^2 - (a_2 + a_1) E^2 + (b^2 - (a_1 + 2a_2) |G_{00}|) \kappa^2 \alpha \beta &= 0.
\end{align*}
\]

(4.28)

This system has a solution only if the following set of constraints, \( \{ |G_{00}| > 0, \kappa > 0, E > 0, b > 0, a_1 > 0, a_2 \neq 0, l \in \mathbb{Z} \} \), is obeyed. The explicit solutions for the parameters are given by

\[
q = 0, \quad a = -1, \quad \gamma = 0, \quad \delta = 1, \quad \alpha = \frac{1}{2} \pm \sqrt{\frac{16 |G_{00}|^2 a_2 + b^2}{2b}}, \quad \beta = 1 - \alpha,
\]

(4.29)

accompanied with two more constraints:

\[
a_1 = \frac{b^2}{|G_{00}|}, \quad a_2 = \frac{b^2 E^2}{4 |G_{00}|^2 \kappa^2 t^2}.
\]

(4.30)

Therefore, Eq. (4.25) becomes the Legendre equation

\[ \Psi''(z) + \left( \frac{1}{z - 1} + \frac{1}{z + 1} \right) \Psi'(z) + \frac{\alpha(1 - \alpha)}{(z - 1)(z + 1)} \Psi(z) = 0. \]  

(4.31)

Quantization condition tells us that the solutions are the Legendre \( P \) and \( Q \) polynomials:

\[ \Psi(z) = c_1 P_{\alpha - 1}(z) + c_2 Q_{\alpha - 1}(z). \]  

(4.32)
On the other hand, the wave function must be square integrable with respect to the measure
\[ \sqrt{\det(G_{ij})} \, d\mu \, d\theta = \frac{\sin \mu}{2} \, d\mu \, d\theta = -\frac{1}{2} \, dz \, d\theta, \quad 0 \leq \theta \leq \pi, \quad 0 \leq z \leq 1. \] (4.33)
The requirement of quadratic integrability sets \( c_2 = 0 \), so the solution to Eq. (4.32) becomes \( \Psi(z) = cP_n(z) \). Therefore, the normalized wave functions (4.20) have the following explicit form
\[ \Psi_{n,l}(z,\theta) = \sqrt{\frac{2(2n+1)}{\pi}} P_n(z) e^{i\theta}, \quad l, n \in \mathbb{Z}. \] (4.34)
Let us turn to the energy spectrum. For \( \Psi(z) = P_{\alpha-1=n}(z) \) one can easily find
\[ E^2 = n(n+1)|G_{00}|\kappa^2 = n(n+1)\kappa \left( \kappa + \frac{b}{2} \right), \] (4.35)
where the constant \( b \) is defined in Eq. (4.14). Taking the square root one arrives at the energy spectrum
\[ E = n(n+1)\kappa \left( \kappa + \frac{b}{2} \right). \] (4.36)
We can now proceed with corrections to the energy. To do that, it is convenient to write the potential (4.11) in the form
\[ U(\mu) = \frac{\kappa^2}{4} (|G_{00}| (a_1 + a_2 \sin^2 \mu) - b^2). \] (4.37)
It is more convenient to work in terms of the new variable \( z \), where the potential becomes
\[ U(z) = \frac{\kappa^2}{4} (|G_{00}| (a_1 + a_2 (1 - z^2)) - b^2). \] (4.38)
However, it is easy to observe that due to the additional constraints (4.30) and (4.35) the expression for the potential greatly simplifies:
\[ U(z) = \frac{\kappa^2 b^2 n(n+1)}{16 l^2} (1 - z^2). \] (4.39)
We should note that in the last expression we used the original constants from the string ansatz. In the perturbation theory first correction to the energy is given then by the expression:
\[ \delta E^2 = \frac{\lambda}{2} \int_{z=0}^{z=1} \int_{\theta=0}^{\theta=\pi} |\Psi_{n,l}(z,\theta)|^2 U(z) \, dz \, d\theta \]
\[ = \lambda \frac{\kappa^2 b^2 n(n+1)(2n+1)}{16 l^2} \int_{0}^{1} (1 - z^2) |P_n(z)|^2 \, dz. \] (4.40)
Hence, for the first quantum correction to the energy, we find
\[ \delta E^2 = \lambda \frac{\kappa^2 b^2 n(n+1)(2n+1)}{16 l^2} \int_{0}^{1} (1 - z^2) |P_n(z)|^2 \, dz \]
\[ = \lambda \frac{\kappa^2 b^2 n(n+1)}{16 l^2} \left( (2n+1) \int_{0}^{1} P_n^2(z) \, dz - (2n+1) \int_{0}^{1} z^2 P_n^2(z) \, dz \right) \]
\[ = \lambda \frac{\kappa^2 b^2 n(n+1)}{16 l^2} \left( 1 - \frac{2n^2 + 2n - 1}{(2n-1)(2n+3)} \right) = \lambda \frac{\kappa^2 b^2 n(n+1)(n^2 + n - 1)}{8 l^2} \frac{1}{(2n-1)(2n+3)}. \]
thus one has

$$\delta E^2 = \lambda \kappa b^2 \frac{n(n+1)(n^2+n-1)}{8T^2(2n-1)(2n+3)}. \quad (4.41)$$

In order to obtain Eq. (4.41) we took advantage of the following relations:

$$\int_0^1 P_n^2(z) \, dz = \frac{1}{2n+1}, \quad \int_0^1 z^2 P_n^2(z) \, dz = \frac{2n^2 + 2n - 1}{(2n-1)(2n+1)(2n+3)}. \quad (4.42)$$

Although we will consider only the first correction term, it is straightforward to calculate also higher corrections to the energy, which have the form

$$\delta E^2(2s) \propto \int_0^1 (1 - z^2)^s |P_n(z)|^2 \, dz = \sum_{k=0}^s (-1)^k \binom{s}{k} \int_0^1 x^{2k} |P_n(z)|^2 \, dz. \quad (4.43)$$

The last integral is evaluated in [51]:

$$\int_0^1 x^{2k} |P_n(z)|^2 \, dz = 2^{-2n} (2n)! \frac{\Gamma(2k+1)}{(n!)^2} \frac{3F_2(-n, -n, \frac{2(k-n)+1}{2}, -2n, k-n+1)}{2\Gamma(2k-n+1)}. \quad (4.44)$$

Combining Eqs. (4.35) and Eq. (4.41) one finds the corrected energy

$$E = \sqrt{n(n+1)} \kappa \left( \kappa + \frac{b}{2} + \frac{\kappa b^2}{8T^2(2n-1)(2n+3)} \lambda \right)^{1/2}. \quad (4.45)$$

By expanding the square root up to first order in \(\lambda\),

$$E = \frac{1}{2} \sqrt{2\kappa \nu(n+1)(b+2\kappa)} \left(1 + \frac{b^2 \kappa \lambda (n^2+n-1)}{8T^2(4n(n+1)-3)(b+2\kappa)}\right) + O(\lambda^2), \quad (4.46)$$

one can calculate the anomalous dimension

$$\Delta = \frac{b^2 \kappa \lambda (n^2+n-1) \sqrt{2\kappa \nu(n+1)(b+2\kappa)}}{16T^2(4n(n+1)-3)(b+2\kappa)}. \quad (4.47)$$

Considering \(L \neq 0\), from the first twisted boundary condition Eq. (2.26) one finds that the string only pulsates in \(Schr_5\), i.e. \(J = 0\). This is due to the fact that \(x^-\) does not depend on \(\sigma\), as it is obvious from Eqs. (B.3) and (3.37). On the other hand, the second boundary condition (2.27) leads to the following relation between the winding number \(n^1\) and the shift \(L\):

$$n^1 = m - \frac{LP_-}{2\pi}, \quad (4.48)$$

where we have used the ansatz for \(\chi = n^1 \sigma\). From equation (4.48) we find that the energy (4.35) and its first quantum correction (4.41) explicitly depend on the shift \(L\).

Finally, the classical energy of the string is given by

$$E_{cl} = -\int_{-L/2}^{L/2} d\sigma \frac{\partial \mathcal{L}}{\partial (\partial_\tau T(\tau, \sigma))} = -\frac{L^2}{4\alpha'^2 \pi} \left( \frac{\hat{\mu}}{Z^1} (2n^1 + A) - 2\alpha' \kappa \left( \frac{\hat{\mu}^2}{Z^1} + 1 \right) \right) = \frac{L^2 \kappa}{2\pi \alpha' \sigma}, \quad (4.49)$$

20
where
\[ \hat{\mu} \equiv \frac{2n^1 + A}{2\alpha' \kappa}. \]

(4.50)

One notes that the classical energy depends explicitly on the shift \( L \).

At the end of this section we summarize our results for the energy spectrum of the pulsating strings in \( \text{Schr}_5 \times S^5 \) and the anomalous dimensions of the operators in the corresponding dual gauge theory. The uncorrected energy levels \( E \) of the quantized system of pulsating strings are given by
\[ E = \sqrt{n(n+1)\kappa \left( \kappa + \frac{b}{2} \right)}, \]

(4.51)

where \( n \) is the principal quantum number and \( b \) is the contribution from the \( B \)-field in Eq. (4.14). The 1-loop corrected energy \( E_{\text{(1-loop)}} \) yields
\[ E_{\text{(1-loop)}} = \sqrt{n(n+1)\kappa \left( \kappa + \frac{b}{2} + \frac{\kappa b^2}{8l^2} \left( \frac{n^2 + n - 1}{(2n-1)(2n+3)} \right) \lambda \right)^{1/2}}, \]

(4.52)

where \( \lambda \) is the \textquote{t’ Hooft} coupling constant and \( l \) is an angular quantum number from Eq. (4.21). The anomalous dimension \( \Delta \) of the Young-Mills operators from the dual gauge theory reads
\[ \Delta = \frac{b^2 \kappa \lambda (n^2 + n - 1) \sqrt{2kn(n+1)(b+2\kappa)}}{16l^2(4n(n+1) - 3)(b + 2\kappa)}. \]

(4.53)

Finally, the corrected energy levels up to arbitrary orders in perturbation theory can be written by
\[ E_{\text{total}} = \sqrt{E^2 + \sum_{s=1}^{\infty} \delta E_{(s)}^2} = \left[ n(n+1)\kappa \left( \kappa + \frac{b}{2} \right) + \frac{\kappa^2 b^2 n(n+1)(2n+1)2^{-2n}(2n)!}{16l^2(n!)^2} \right]^{1/2} \times \sum_{s=1}^{\infty} \sum_{k=0}^{s} (-1)^k \binom{s}{k} \Gamma(2k+1)_{3}F_{2} \left( -n, -n, \frac{2(k-n)+1}{2}, -2n, k - n + 1 \right) \Gamma(2(k-n+1))^{1/2}. \]

(4.54)

It is important to mention that the exact one-loop correction (4.52) in the considered Schrödinger background may contain also contribution from the fermionic degrees of freedom. However, finding this contribution is fairly complicated even in the case of unbroken supersymmetry [13]. Therefore, we leave this subtle question for a future work.

5 Conclusions

In this paper, we have studied a class of pulsating string solutions in a Schrödinger background. We provided a brief review of the deformations generating the Schrödinger geometry. As a particular case of Drinfel’d-Reshetikhin twist, the solution generating TsT deformations involve the time direction and one spatial dimension in the internal space. The deformation is known also as null Melvin twist transformation.

The study of pulsating strings in particular backgrounds with external fluxes has been implemented for instance in [18] and appeared to be nontrivial. From this perspective
we expected the study of our problem to be also nontrivial. To find pulsating string solutions in Schrödinger background, we have adopted an appropriate pulsating ansatz for the circular string configuration. Considering the bosonic part of the string action in conformal gauge, we have found the relevant equations of motion and Virasoro constraints. The problem of finding periodic solutions imposes certain conditions even after the choice of pulsating string ansatz. The restriction of the parameters leads to several non-trivial cases, all of which have analytic solutions as combinations of trigonometric and Jacobi elliptic functions.

An important key point of pulsating strings is that they reduce the problem to the (squared) Hamiltonian, which has the form of a point-particle Hamiltonian. It allows clearly to distinguish an effective string potential, which, being multiplied by the coupling $\lambda$, is used later for perturbative expansion. Obtaining the effective wave function for the problem, we used perturbation theory to obtain the corrections to the energy. The latter, due to AdS/CFT correspondence, are related to the anomalous dimensions of operators in the dual gauge theory. The unperturbed energy spectrum turned out to be equidistant and independent on the components of the $B$-field. On the other hand, the first correction picked up a factor proportional to the $B$-field. Furthermore, we have also obtained the explicit expressions for the higher order corrections in terms of generalized hypergeometric functions.

To the best of our knowledge, the obtained solutions are the first pulsating type solutions in Schrödinger backgrounds and in backgrounds with non-relativistic gauge dual in general. Thus, the energy and the obtained corrections are the first examples of contributions from this string sector to the anomalous dimensions in non-relativistic dual gauge theory. One should note that giant magnon solutions in spherical part extended in Schrödinger space have been found in [26] (see also [25]) and all the results are complementary to each other.

There are several interesting questions, which could be addressed further. First of all, it would be interesting to identify the operators on the gauge theory side whose anomalous dimension correspond to the various contributions in the energy spectrum. Some operators have been discussed in [19]. We didn’t touch these issues, but it is worth to note that the wave functions obtained in two different approaches in [19] are also Legendre polynomials as in our considerations. The operators discussed in [19] could give a clue in this direction. Next, one can consider perturbations around the pulsating string solutions, which, at the quantum level, could give contributions to the scaling relations. It is also of great interest to perform an analysis comparing our results to that in gauge theory side, such as finding the Yang-Mills operators corresponding to these string configurations. The study of these problems in some other backgrounds, $Schr_5 \times T^{1,1}$ for instance, could also be of particular interest. Finally, one should consider that the exact one-loop correction (4.52) contains potential contributions from the fermionic sector. However, this contribution is fairly complicated even in the case of unbroken supersymmetry [43]. In the case of Schrödinger backgrounds, fermionic contribution is even more subtle question and remains to be done. We are planning to address these issue in a future publication.

A A remark on more general deformations

As we mentioned in the main text, the most general deformations preserving integrability containing the TsT techniques, is based on the so-called Drinfel’d-Reshetikhin (DR) twist. In this Appendix we present a brief review of the DR twist following mainly [19].

To this end, let us consider the scattering matrix $S$. The DR twist of the scattering matrix is realized as

$$S \rightarrow \tilde{S} = FSF,$$

where $F$ is a constant solution of the Yang-Baxter (YB) equations.

$$F_{ab}F_{ac}F_{bc} = F_{bc}F_{ac}F_{ab}. \quad (A.6)$$

Then Drinfel’d twist is the most general linear transformation of the form

$$R_{ab}(u) \rightarrow \tilde{R}_{ab}(u) = F_{ab}R_{ab}(u)F_{ab}, \quad (A.5)$$

which preserves integrability. The constant matrix $F_{ab}$ satisfies the following conditions:

- It is a constant solution of YB equations:
  $$F_{ab}F_{ac}F_{bc} = F_{bc}F_{ac}F_{ab}. \quad (A.6)$$

- Obey the associativity condition: constant solution of YB equation with an intertwining relation with the R-matrix:
  $$R_{ab}(u)F_{ca}F_{cb} = F_{cb}F_{ca}R_{ab}(u). \quad (A.7)$$

- To preserve regularity of the R-matrix, the twist should satisfy an additional constraint dubbed to as unitarity condition:
  $$F_{ab}F_{ba} = 1. \quad (A.8)$$

Looking at the discussion in the beginning of this Section, one can see that a wide class of solutions is associated with the commuting charges. For instance, having a set of commuting in $V_a$ charges $Q^i_a$, $[Q^i_a, Q^j_a] = 0$, the condition

$$e^{i\omega_k Q^i_a}e^{i\omega_l Q^j_a}R_{ab}(u) = R_{ab}(u)e^{i\omega_l Q^k_a}e^{i\omega_l Q^l_a} \quad (A.9)$$

for each $k, l$ means that $e^{i\omega_k Q^k_a}$ is a non-degenerate linear transformation on $V_a$ and a symmetry of $R_{ab}$. It is simple exercise to check that the following $F_{ab}$ satisfies YB equation:

$$F_{ab} = K_aK_b^{-1}, \quad K_a = e^{i\omega_k Q^k_a}. \quad (A.10)$$

To summarize, one can construct the Drinfel’d twist operator as (summation over $i, j$ is understood):

$$F_{ab} = e^{i\gamma_{ij}Q^i_aQ^j_b}, \quad (A.11)$$

where $\gamma_{ij} = -\gamma_{ji}$. 

23
B Schrödinger space in Global coordinates

We start with the observation that the Schrödinger metric (2.20) in local coordinates consists of two pieces

\[ ds^2 = -\ell^2 \frac{\hat{\mu}^2 (dx^+)^2}{z^4} + ds^2_{AdS_5}, \]  

(B.1)

where the second part is the AdS$_5$ metric in light-cone coordinates

\[ ds^2_{AdS_5} = \frac{\ell^2}{z^2} (2dx^+ dx^- + d\vec{x}^2 + dz). \]  

(B.2)

We first focus on the AdS piece. To obtain the metric in global coordinates we make the following transformations

\[ x^+ = \tan T, \quad x^- = V - \frac{1}{2} (Z^2 + \vec{X}^2) \tan T, \quad z = \frac{Z}{\cos T}, \quad \vec{x} = \frac{\vec{X}}{\cos T}. \]  

(B.3)

Thus

\[ dx^+ = \frac{dT}{\cos^2 T}, \quad dx^- = dV - \tan T \left( ZdZ + \vec{X} d\vec{X} \right) - \frac{1}{2} \left( Z^2 + \vec{X}^2 \right) \frac{dT}{\cos^2 T}, \]
\[ dz = \frac{dZ}{\cos T} + \frac{Z \sin T dT}{\cos^2 T}, \quad d\vec{x} = \frac{1}{\cos T} \left( d\vec{X} + \vec{X} \tan T dT \right). \]  

(B.4)

Substituting (B.4) into (B.2) we find the metric of AdS$_5$ in global coordinates

\[ ds^2_{AdS_5} = \frac{\ell^2}{Z^2} \left( 2dT dV - (Z^2 + \vec{X}^2) dT^2 + d\vec{X}^2 + dZ^2 \right). \]  

(B.5)

To obtain the first part we just need the relation

\[ \frac{\hat{\mu}^2}{z^4} dx^+^2 = \frac{\mu^2}{Z^4} dT^2. \]  

(B.6)

Putting everything together we obtain the Schrödinger metric and the B-field in global coordinates in the form

\[ \frac{ds^2_{Schr}}{\ell^2} = -\left( \frac{\hat{\mu}^2}{Z^4} + 1 \right) dT^2 + \frac{2dT dV - \vec{X}^2 dT^2 + d\vec{X}^2 + dZ^2}{Z^2}, \]  

(B.7)

\[ \alpha' B_{(2)} = \frac{\ell^2 \hat{\mu} dT}{Z^2} \wedge (d\hat{\chi} + P). \]  

(B.8)

C Other pulsating string solutions

In this appendix we consider the solutions for the other cases from (i), (ii) and (iii).

- For $C > 0, K > 0$ and $u_1 < -1 < u_2 \leq u(\tau) \leq 1$:

\[ \theta(\tau) = \arccos \left( \frac{1 - \frac{1 - u_2}{|u_1| + u_2} |u_1|^2 \text{sn}^2 \left( \sqrt{C(n^3)^2} \left( |u_1| + u_2 \right) \tau, r \right)}{1 + \frac{1 - u_2}{|u_1| + u_2} \text{sn}^2 \left( \sqrt{C(n^3)^2} \left( |u_1| + u_2 \right) \tau, r \right)} \right). \]  

(C.1)
For $C > 0$, $K > 0$ and $-1 < u_1 < u_2 \leq u(\tau) \leq 1$:

$$
\theta(\tau) = \arccos \left( \frac{1 - \frac{1 - u_2}{1 + u_2} \sin^2 \left( \sqrt{2^{-1} C (n^3)^2 (1 - u_1)(1 + u_2)} \tau, r \right)}{1 - \frac{1 - u_2}{1 + u_2} \sin^2 \left( \sqrt{2^{-1} C (n^3)^2 (1 - u_1)(1 + u_2)} \tau, r \right)} \right). \quad (C.2)
$$

For $C > 0$, $K > 0$ and $-1 \leq u(\tau) \leq u_1 < u_2 < 1$:

$$
\theta(\tau) = \arccos \left( \frac{u_1 - \frac{1 + u_1}{1 + u_2} u_2 \sin^2 \left( \sqrt{2^{-1} C (n^3)^2 (1 - u_1)(1 + u_2)} \tau, r \right)}{1 - \frac{1 + u_1}{1 + u_2} \sin^2 \left( \sqrt{2^{-1} C (n^3)^2 (1 - u_1)(1 + u_2)} \tau, r \right)} \right). \quad (C.3)
$$

For $C > 0$, $K > 0$ and $-1 \leq u(\tau) \leq u_1 < 1 < u_2$:

$$
\theta(\tau) = \arccos \left( \frac{1 - \frac{2u_1}{1 + u_1} \sin^2 \left( \sqrt{2^{-1} (n^3)^2 (1 + u_1)(u_2 - 1)} \tau, r \right)}{1 - \frac{2}{1 + u_1} \sin^2 \left( \sqrt{2^{-1} C (n^3)^2 (1 - u_1)(1 + u_2)} \tau, r \right)} \right). \quad (C.4)
$$

For $C > 0$, $K > 0$ and $-1 \leq u(\tau) \leq 1 < u_1 < u_2$:

$$
\theta(\tau) = \arccos \left( \frac{u_1 - \frac{1 + u_1}{2} \sin^2 \left( \sqrt{C (n^3)^2 (u_2 - u_1)} \tau, r \right)}{1 - \frac{1 + u_1}{2} \sin^2 \left( \sqrt{C (n^3)^2 (u_2 - u_1)} \tau, r \right)} \right). \quad (C.5)
$$

For $C < 0$, $K > 0$, $u_1 < -1 \leq u(\tau) \leq u_2 < 1$ and $q = \sqrt{\frac{(b - c)(a - d)}{(a - c)(b - d)}}$:

$$
\theta(\tau) = \arccos \left( \frac{u_2 - \frac{1 + u_2}{2} \sin^2 \left( \sqrt{|C| (n^3)^2 (u_2 + |u_1|)} \tau, q \right)}{1 - \frac{1 + u_2}{2} \sin^2 \left( \sqrt{|C| (n^3)^2 (u_2 + |u_1|)} \tau, q \right)} \right). \quad (C.6)
$$

For $C < 0$, $K > 0$ and $u_1 < -1 \leq u(\tau) \leq 1 < u_2$:

$$
\theta(\tau) = \arccos \left( \frac{1 - \frac{2u_2}{1 + u_2} \sin^2 \left( \sqrt{2^{-1}|C| (n^3)^2 (1 + |u_1|)(1 + u_2)} \tau, q \right)}{1 - \frac{2}{1 + u_2} \sin^2 \left( \sqrt{2^{-1}|C| (n^3)^2 (1 + |u_1|)(1 + u_2)} \tau, q \right)} \right). \quad (C.7)
$$

For $C < 0$, $K > 0$ and $-1 < u_1 \leq u(\tau) \leq u_2 < 1$:

$$
\theta(\tau) = \arccos \left( \frac{u_2 - \frac{u_2 - u_1}{1 - u_1} \sin^2 \left( \sqrt{2^{-1}|C| (n^3)^2 (1 - u_1)(1 + u_2)} \tau, q \right)}{1 - \frac{u_2 - u_1}{1 - u_1} \sin^2 \left( \sqrt{2^{-1}|C| (n^3)^2 (1 - u_1)(1 + u_2)} \tau, q \right)} \right). \quad (C.8)
$$
For $C < 0$, $K > 0$ and $-1 < u_1 \leq u(\tau) \leq 1 < u_2$:

$$
\theta(\tau) = \arccos \left( \frac{1 - \frac{1 - u_1}{u_2 - u_1} \left( \sqrt{|C|(n^3)^2 (u_2 - u_1)} \right)}{1 - \frac{1 - u_1}{u_2 - u_1} \left( \sqrt{|C|(n^3)^2 (u_2 - u_1)} \right)} \right). \quad (C.9)
$$

For $C > 0$ and $K = 0$, we have

$$
\int_{1}^{u} \frac{du}{|u - u_1|\sqrt{1 - u^2}} = -\sqrt{2C(n^3)^2} \int_{0}^{\tau} d\tau. \quad (C.10)
$$

Hence,

$$
\int_{0}^{\theta} \frac{d\theta}{|\cos \theta - u_1|} = \sqrt{2C(n^3)^2} \tau. \quad (C.11)
$$

There are four possible cases:

- $u_1 < -1 \leq u(\tau) \leq 1$, \quad (C.12a)
- $-1 < u_1 \leq u(\tau) \leq 1$, \quad (C.12b)
- $-1 \leq u(\tau) < u_1 < 1$, \quad (C.12c)
- $-1 \leq u(\tau) \leq 1 < u_1$. \quad (C.12d)

The solutions are:

- For $C > 0$, $K = 0$ and $u_1 < -1 \leq u(\tau) \leq 1$:

$$
\tan \left( \frac{\theta}{2} \right) = \sqrt{\frac{|u_1| + 1}{|u_1| - 1}} \tan \left( \sqrt{2^{-1}C(n^3)^2(u_1^2 - 1)} \tau \right). \quad (C.13)
$$

Using the formula $\cos \theta = \frac{1 - \tan^2 \theta}{1 + \tan^2 \theta}$, we evaluate

$$
\theta(\tau) = \arccos \left( \frac{1 - \frac{|u_1| + 1}{|u_1| - 1} \tan^2 \left( \sqrt{2^{-1}C(n^3)^2(u_1^2 - 1)} \tau \right)}{1 + \frac{|u_1| + 1}{|u_1| - 1} \tan^2 \left( \sqrt{2^{-1}C(n^3)^2(u_1^2 - 1)} \tau \right)} \right). \quad (C.14)
$$

- For $C > 0$, $K = 0$ and $-1 \leq u(\tau) \leq 1 < u_1$:

$$
\tan \left( \frac{\theta}{2} \right) = \sqrt{\frac{u_1 - 1}{u_1 + 1}} \tan \left( \sqrt{2^{-1}C(n^3)^2(u_1^2 - 1)} \tau \right), \quad (C.15)
$$

or

$$
\theta(\tau) = \arccos \left( \frac{1 - \frac{u_1 - 1}{u_1 + 1} \tan^2 \left( \sqrt{2^{-1}C(n^3)^2(u_1^2 - 1)} \tau \right)}{1 + \frac{u_1 - 1}{u_1 + 1} \tan^2 \left( \sqrt{2^{-1}C(n^3)^2(u_1^2 - 1)} \tau \right)} \right). \quad (C.16)
$$
• In the following cases \((C > 0, K = 0)\): \(-1 < u_1 \leq u(\tau) \leq 1\) and \(-1 \leq u(\tau) < u_1 < 1\) we do not have periodic solutions.

Now we consider the case \((ii)\), where \(n^1 = 0, A \neq 0\). The first Virasoro constraint provides

\[
\dot{\mu}^2 + \frac{1}{4} \sin^2 \mu \left( \dot{\theta}^2 + (n^2)^2 + (n^3)^2 + 2n^2 n^3 \cos \theta \right) - \left( 1 + \frac{\dot{\mu}^2}{Z^4} \right) \kappa^2 = 0.
\]  

(C.17)

The other equations are as follows.

- For \(Z\):
  \[
  Z^2 = \frac{2\dot{\alpha}' \kappa}{A}.
  \]
  (C.18)

- The next equation is for \(\theta\):
  \[
  \frac{d}{d\tau} \left( \sin^2 \mu \dot{\theta} \right) - n^3 \sin^2 \mu \sin \theta \left( n^2 - \frac{2\dot{\mu} \kappa}{\alpha' Z^2} \right) = 0.
  \]
  (C.19)

- Finally, for \(\mu\) one has
  \[
  \ddot{\mu} + \frac{1}{4} \sin \mu \cos \mu \left( (n^2)^2 + (n^3)^2 - \dot{\theta}^2 + 2n^2 n^3 \cos \theta - \frac{4\dot{\mu} \kappa}{\alpha' Z^2} (n^2 + n^3 \cos \theta) \right) = 0.
  \]
  (C.20)

Once again we substitute the pulsating condition (3.46) into the equation for \(\theta\) to obtain an ordinary differential equation with respect only to \(\theta\):

\[
\frac{d}{d\tau} \left( \frac{\dot{\theta}}{n^2 + n^3 \cos \theta} \right) - n^3 K' \frac{\sin \theta}{n^2 + n^3 \cos \theta} = 0,
\]

(C.21)

where \(K' = n^2 - \frac{2\dot{\mu} \kappa}{\alpha' Z^2}\). Thus, the case \((ii)\), is the same as \((i)\), but with different constant \(K'\).

The last case we consider is \((iii)\): \(n^1 \neq 0, A = 0\). Setting \(A = 0\), we have to solve

\[
A = \sin^2 \mu \left( n^2 + n^3 \cos \theta \right) = 0.
\]

(C.22)

So, the first option is

\[
n^2 + n^3 \cos \theta = 0 \implies \cos \theta = -\frac{n^2}{n^3} \implies |n^2| \leq |n^3|, \quad \theta = \text{const.}
\]

(C.23)

Next step is to check the first Virasoro constraint:

\[
\ddot{\mu}^2 = \left( 1 + \frac{\dot{\mu}^2}{Z^4} \right) \kappa^2 - (n^1)^2 - \frac{1}{4} \sin^2 \mu \left( (n^3)^2 - (n^2)^2 \right).
\]

(C.24)

The equations of motion are as follows.

- For \(Z\) we find
  \[
  Z^2 = \frac{\dot{\mu} \alpha' \kappa}{n^1}.
  \]
  (C.25)
The equation of motion for $\theta$ provides the relation
\[ Z^2 = \frac{2\hat{\mu}\kappa}{\alpha'(2n^1 + n^2)}. \] (C.26)

The only non-constant equation is for $\mu$:
\[ \dot{\mu}^2 = N^2 - \frac{1}{4} \sin^2 \mu \left( (n^3)^2 - (n^2)^2 \right). \] (C.27)

From Eqs. (C.25) and (C.26) we find the following relation between the windings $n^1$ and $n^2$:
\[ \frac{n^2}{n^1} = 2 \left( \frac{1}{\alpha'^2} - 1 \right). \] (C.28)

Using Eqs. (C.24), (C.25) and (C.27), one can express for the constant $N^2$ such as
\[ N^2 = \kappa^2 + (n^1)^2 \left( \frac{1}{\alpha'^2} - 1 \right). \] (C.29)

Now, we are in a position to integrate the equation for $\mu$:
\[
\int_0^\mu \frac{d\mu}{\sqrt{1 - k^2 \sin^2 \mu}} = F(\mu, k) = \pm |N| \int_0^\tau d\tau,
\] (C.30)

where $4N^2k^2 = (n^3)^2 - (n^2)^2$. Finally, it is straightforward to obtain
\[ \sin \mu = \pm \text{sn}(|N|\tau, k), \] (C.31)

or explicitly for $\mu$
\[ \mu(\tau) = \pm \arcsin \left( \text{sn}(|N|\tau, k) \right). \] (C.32)

The second solution of Eq. (C.22) is $n^2 = n^3 = 0$. The corresponding non-zero Virasoro constraint becomes
\[ \dot{\mu}^2 + \frac{1}{4} \sin^2 \mu \dot{\theta}^2 - N^2 = 0. \] (C.33)

The equations of motion provide the following relations:

- For the constant $Z$ one obtains
\[ Z^2 = \frac{\hat{\mu}\alpha'\kappa}{n^1}. \] (C.34)

- The equation for $\theta$ gives
\[ \frac{d}{d\tau} \left( \sin^2 \mu \dot{\theta} \right) = 0. \] (C.35)

- The equation for $\mu$ is also non-trivial:
\[ \frac{d}{d\tau} (\dot{\mu}) - \frac{1}{4} \sin \mu \cos \mu \dot{\theta}^2 = 0. \] (C.36)
Now we multiply Eq. (C.36) by $\sin \mu$ and use Eq. (C.33) to express $\sin^2 \mu \dot{\theta}^2 = -4(\dot{\mu}^2 - N^2)$. The resulting equation is given by

$$\sin \mu \frac{d}{d\tau} (\dot{\mu}) + \cos \mu (\dot{\mu}^2 - N^2) = 0.$$  \hfill(37)

By the fact that $\frac{d}{d\tau} (\dot{\mu} \sin \mu) = \sin \mu \frac{d}{d\tau} (\dot{\mu}) + \dot{\mu}^2 \cos \mu$, the last equation becomes

$$\frac{d}{d\tau} (\dot{\mu} \sin \mu) - N^2 \cos \mu = 0,$$  \hfill(C.38)

or

$$\frac{d^2}{d\tau^2} (\cos \mu) + N^2 \cos \mu = 0.$$  \hfill(C.39)

Its solution is

$$\mu(\tau) = \arccos \left( C_1 \cos(N\tau) + C_2 \sin(N\tau) \right).$$  \hfill(C.40)

Integrating Eq. (C.35) we obtain

$$\sin^2 \mu \dot{\theta} = D = \text{const.}$$  \hfill(C.41)

We can integrate this equation with respect to $\theta$ and $\tau$:

$$\int_0^\theta d\theta = \int_0^\tau \frac{D}{1 - \cos^2 \mu} d\tau = \int_0^\tau \frac{D}{1 - (C_1 \cos(N\tau) + C_2 \sin(N\tau))^2} d\tau,$$  \hfill(C.42)

where we used Eq. (C.40). The solution is

$$\theta(\tau) = \frac{D}{N \sqrt{C_1^2 + C_2^2} - 1} \arctanh \left( \frac{C_1 C_2 + (C_2^2 - 1) \tan(N\tau)}{\sqrt{C_1^2 + C_2^2} - 1} \right),$$  \hfill(C.43)

with an additional constraint $C_1^2 + C_2^2 < 1$ which is a requirement for the solution to be periodic.
