Abstract

Conversion of Chinese graphemes to phonemes (G2P) is an essential component in Mandarin Chinese Text-To-Speech (TTS) systems. One of the biggest challenges in Chinese G2P conversion is how to disambiguate the pronunciation of polyphones—characters having multiple pronunciations. Although many academic efforts have been made to address it, there has been no open dataset that can serve as a standard benchmark for fair comparison to date. In addition, most of the reported systems are hard to employ for researchers or practitioners who want to convert Chinese text into pinyin at their convenience. Motivated by these, in this work, we introduce a new benchmark dataset that consists of 99,000+ sentences for Chinese polyphone disambiguation. We train a simple neural network model on it, and find that it outperforms other pre-existing G2P systems. Finally, we package our project and share it on PyPi.

Index Terms: Grapheme-to-phoneme conversion, Chinese polyphone disambiguation, text-to-speech, Python package

1. Introduction

Chinese grapheme to phoneme (G2P) conversion is a task that changes Chinese text into pinyin, an official Romanization system of Chinese. It is considered essential in Chinese Text-to-Speech (TTS) systems as unlike English alphabets, Chinese characters represent the meanings, not the sounds. A major challenge in Chinese G2P conversion is how to disambiguate the pronunciation of polyphones—characters having more than one pronunciation. In the example below, the first 的 is pronounced de, while the second one is pronounced di.

input: 今天来的目的是什么?

output: jīn tiān lái de mì di shěn me ?

There have been many academic efforts to tackle this problem [1, 2, 3, 4, 5, 6, 7]. However, we find there exist two main problems with them. First, there are no standard benchmark datasets for Chinese polyphone disambiguation. As shown in Table 1, most past works collect copyright data from the Internet, and annotate themselves. Due to the lack of a public benchmark dataset, they report results on different datasets. This makes it hard to compare different models. Second, all of the reports in Table 1 do not lead to the release of source code or packages where researchers or practitioners can convert Chinese text into pinyin at their convenience.

Motivated by these, we construct and release a new Chinese polyphone dataset and a Chinese G2P library using it. Our contribution is threefold:

- We create a new Chinese polyphonic character dataset, which we call Chinese Polyphones with Pinyin (CPP). It is freely available via our GitHub repository [8].
- With the CPP dataset, we train simple neural network models for the Chinese polyphonic character to pinyin task. We find that our best model outperforms other existing G2P systems.
- We build a user-friendly Chinese G2P Python library based on one of our models, and share it on PyPi.

2. Related Work

There are several works for Chinese polyphone disambiguation. They can be categorized into the traditional rule-based approach [5, 6, 7] and the data driven approach [1, 2, 3, 4, 10]. The rule-based approach chooses the pronunciation of the polyphonic character based on predefined complex rules along with a dictionary. However, this requires a substantial amount of linguistic knowledge. The data driven approach, by contrast, adopts statistical methods such as Decision Tree [3] or Maximum Entropy Model [2, 10]. Recently [10] use bidirectional Long Short-Term Memory (LSTM) [11] to extract diverse features on the character, word, and sentence level. However, as they depend on external tools such as a word segmenter and a Part-Of-Speech tagger which are not perfect, they are inherently prone to the cascading errors.

3. Chinese Characters and Polyphones

We explore what percentage of Chinese characters are polyphones to gauge how important the polyphone disambiguation

*Equal contribution.

Table 2: Percentage of Chinese polyphones in Wikipedia. A monophone is a character that has a single pronunciation.

| Total | Monophones | Polyphones |
|-------|------------|------------|
| # unique char. | 17,720 | 16,929 (95.60%) | 762 (4.30%) |
| # characters | 363M | 296M (81.51%) | 67M (18.49%) |

Table 3: Basic statistics of CPP dataset

| Total | Train | Dev. | Test |
|-------|-------|------|------|
| # sentences | 99,264 | 79,117 | 9,893 | 10,254 |
| # characters per sent | 31.30 | 31.29 | 31.24 | 31.43 |
| # polyphones | 623 | 623 | 623 | 623 |

Table 4: The number of polyphones and sentences in the CPP dataset by the number of possible pronunciations

| # Pronunciations | # Polyphones | # Sentences |
|------------------|--------------|-------------|
| Total 623 (100%) | 99,264 (100%) |
| 2 | 553 (88.8%) | 87,584 (88.2%) |
| 3 | 60 (9.6%) | 10,162 (10.2%) |
| 4-5 | 10 (1.6%) | 1,518 (1.6%) |

Figure 1: The number of sentences for each polyphonic character in CPP dataset. On average, a polyphonic character has about 159 sentences.

4. The CPP (Chinese Polyphones with Pinyin) Dataset

In this section, we introduce the CPP dataset—a new Chinese polyphonic character dataset for the polyphone disambiguation task.

4.1. Data Collection

We split the aforementioned Chinese text in Wikipedia into sentences. If a sentence contains any traditional Chinese characters, it is filtered out. Also, sentences whose length is more than 50 characters or less than 5 characters are excluded. Then, we leave only the sentences having at least one polyphonic character. A special symbol _ (U+2581) is added to the left and right of a polyphonic character randomly chosen in a sentence to mark the target polyphone. Finally, in order to balance the number of samples across the polyphones, we clip the minimum and maximum number of sentences for any polyphones to 10 and 250, respectively.

4.2. Human Annotation

We have two native Chinese speakers annotate the target polyphonic character in each sentence with appropriate pinyin. To make it easier, we provide them with a set of possible pronunciations extracted from CC-CEDICT for the polyphonic character. Next, we ask the annotators to choose the correct one among those candidates. It is worth noting that we do not split the data in half for assignment. Instead, we assign both of the annotators the same entire sentences. Then, we compare each of their annotation results, and discard the sentence if they do not agree.

4.3. Data Split

As a result, 99,264 sentences, each of which includes a target polyphone with the correct pinyin annotation, remain. Subsequently, we group them by polyphones. For each group, we shuffle and split the sentences into training, development, and test sets at the ratio of 8:1:1. Details are in Table 3.

4.4. Statistics

Figure 2 shows how many sentence samples each of the polyphones in the CPP dataset has. 73.5% of polyphones (458 of 623) have 150-250 samples, while only 13.8%, i.e., 86 polyphones have less than 50 samples. Obviously, this comes from the differences in the frequency of polyphones.

We also present how many pronunciations the polyphones in the dataset can have in Table 4. Among 623 polyphones in the dataset, 553 (88.8%) have two possible pronunciations. There are 60 (9.6%) polyphones in the dataset that can have three pronunciations, and the rest 10 can have up to five pronunciations. All things being equal, we suppose the more pronunciations a polyphone can have, the more challenging it is for a predictor to disambiguate its correct pronunciation.

Finally, we explore how dominant the most frequent pronunciation in each polyphone is. As shown prominently in Figure 2, 73.52% of polyphones are associated with a single prevalent pronunciation that accounts for more than 90% of all samples. This implies that majority vote—picking up the pronun-
Let \( x_1, \ldots, x_T \) be a sequence of characters, which represent a sentence. We map each character \( x_t \) to the dense embedding vector \( e_t \in \mathbb{R}^d \) with a randomly initialized lookup matrix \( E \in \mathbb{R}^{V \times d} \), where \( V \) is the number of all characters and \( d \) is the dimension of the embedding vectors. We denote a sequence of character embedding vectors by \( e = (e_1, \ldots, e_T) \).

5. Method

We consider Chinese polyphone disambiguation as a classification problem and train a function, parameterized by neural networks, which maps a polyphonic character to its pronunciation.

We do not use any external language processing tools such as word segmenter, entity recognizer, or Part-Of-Speech tagger. Instead, we take as input a sequence of characters and train the network in the end-to-end manner.

5.1. Embedding

Let \( x = (x_1, \ldots, x_T) \in \mathbb{R}^T \) a sequence of characters, which represent a sentence. We map each character \( x_t \) to the dense embedding vector \( e_t \in \mathbb{R}^d \) with a randomly initialized lookup matrix \( E \in \mathbb{R}^{V \times d} \), where \( V \) is the number of all characters and \( d \) is the dimension of the embedding vectors. We denote a sequence of character embedding vectors by \( e = (e_1, \ldots, e_T) \).

5.2. Bidirectional LSTM Encoder

The bidirectional Long Short-Term Memory (Bi-LSTM) [11] network is used to encode the contextual information of the polyphonic character. At any time step \( t \), the representation \( \mathbf{h}_t \) is the concatenation of the forward hidden state \( (\mathbf{h}_t^f) \) and the backward hidden state \( (\mathbf{h}_t^b) \).

\[
\mathbf{h}_t = \text{LSTM}(e_t, \mathbf{h}_{t-1}^b)
\]

\[
\mathbf{h}_t = \tilde{\text{LSTM}}(e_t, \mathbf{h}_{t-1}^f)
\]

\[
\mathbf{h}_t = \text{concat}((\mathbf{h}_t^f, \mathbf{h}_t^b))
\]

5.3. Fully Connected Layers

We use two fully connected layers to transform the encoded information into the classification label. Let \( j \) be the position index of the polyphonic character in the sentence. The concatenated hidden state \( \mathbf{h}_j \) (dotted line in Figure 3) is fed into the two-layered feedforward network followed by the softmax function, yielding the pinyin probability distribution \( \hat{y} \) over all possible pinyin classes as follows:

\[
\hat{y} = (\hat{y}_1, \ldots, \hat{y}_c) = \text{softmax}(g_2(\varphi(g_1(\mathbf{h}_j))))
\]

where \( g_1 \) and \( g_2 \) are fully connected layers, and \( \varphi \) is a non-linear activation function such as ReLU [12], and \( c \) is the number of possible pinyin classes.

5.4. Loss Function

Let \( y = (y_1, \ldots, y_c) \in \mathbb{R}^c \) be a one-hot vector of a true label. We use cross-entropy as a loss function for training. In other words, we minimize the negative log-likelihood to find the optimal parameters \( \theta \), which we denote as \( \hat{\theta} \).

\[
\mathcal{L}(\theta) = - \sum_{j=1}^c y_j \log(\hat{y}_j)
\]

\[
\hat{\theta} = \arg \min_{\theta} \mathcal{L}(\theta)
\]

6. Experiments

6.1. Training

We randomly initialize the character embedding matrix and set its dimension to 64. To find the optimal hyperparameter values, we vary the hidden sizes \( (16, 32, 64) \) and the number of layers in the Bi-LSTM encoder \( (1, 2, 3) \). The dimension of the last two fully connected layers is set to 64, and ReLU [12] is used as the activation function. We train all the models with Adam optimizer [13] and batch size 32 for 20 epochs. All the experiments are run five times with different random seeds.
We develop a simple Chinese G2P library in Python, dubbed g2pM, using one of our pretrained models. The package provides simple APIs for operation. With a few lines of code, users can convert any Chinese text into a sequence of pinyin. An example is available in Figure 4.

We also compare our model with three open-source libraries: xpyinyin, pypinyin, and g2pC. xpyinyin and pypinyin are based on rules, while g2pC uses Conditional Random Fields (CRFs) for polyphone disambiguation. Our model outperforms the baseline—majority vote—and other systems by large margin. As shown in Table 6, ours reaches 97.31% accuracy on the test set, which is 4.33% point higher than the majority vote system. That our simple neural model works the best tells us two things. One is that it is simple but powerful enough so we do not need any complicated rules. Another is that it is not too simple for the naive majority vote to beat.

We also compare our model with three open-source libraries: xpyinyin, pypinyin, and g2pC. xpyinyin and pypinyin are based on rules, while g2pC uses Conditional Random Fields (CRFs) for polyphone disambiguation. Our model outperforms the baseline—majority vote—and other systems by large margin. As shown in Table 6, ours reaches 97.31% accuracy on the test set, which is 4.33% point higher than the majority vote system. That our simple neural model works the best tells us two things. One is that it is simple but powerful enough so we do not need any complicated rules. Another is that it is not too simple for the naive majority vote to beat.

7. g2pM: a Grapheme-to-Phoneme Conversion Library for Mandarin Chinese

We develop a simple Chinese G2P library in Python, dubbed g2pM, using one of our pretrained models. The package provides an easy-to-use interface in which users can convert any Chinese text into a sequence of pinyin. We share it on PyPi at https://pypi.org/g2pM.

7.1. Packaging

We implement g2pM purely in Python. In order to minimize the number of external libraries that must be pre-installed, we first rewrite our Pytorch inference code in NumPy [15]. Our best model is 1.7MB in size, and the package size is a little bigger, 2.1MB, as it includes some contents of CC-CEDICT. Details are shown in Table 7 g2pM works like the following. Given a Chinese text, g2pM checks every character if it is a polyphonic character. If so, the neural network model returns its predicted pronunciation. Otherwise, the pronunciation of the (monophonic) character is retrieved from the dictionary contained in the package.

### Table 7: Breakdown of g2pM. × denotes the number of layers.

| Layer                  | Size   |
|------------------------|--------|
| Embedding              | 64     |
| LSTM ×1                | 64     |
| Fully Connected ×2     | 64     |
| Total # parameters     | 477,228|
| Model size             | 1.7MB  |
| Package size           | 2.1MB  |

7.2. Usage

g2pM provides simple APIs for operation. With a few lines of code, users can convert any Chinese text into a sequence of pinyin. An example is available in Figure 4.

8. Conclusion

We proposed a new benchmark dataset for Chinese polyphone disambiguation, which is freely and publicly available. We trained simple deep learning models, and created a Python package with one of them. We hope our dataset and library will be helpful for researchers and practitioners.
