We investigated the usefulness of age-specific cutoffs for screening of urinary tract infections (UTIs) in Korean outpatients, using the automated urine analyzer UF-1000i (Sysmex, Kobe, Japan). We retrospectively reviewed outpatient medical records. Urine samples of 7,443 outpatients from January 2010 to December 2017 were analyzed using urine culture and UF-1000i. ROC curves were calculated for each UF-1000i parameter based on the culture results. There were 1,398 culture positive samples, 5,774 culture negative samples, and 271 contaminated samples. UF-1000i had an area under the curve of ≥0.9 in outpatients >15 years. The appropriate cutoffs, which are the sum of bacterial (B-A-C) and white blood cell (WBC) counts, were 297.10/µL (15–24 years), 395.65/µL (25–44 years), 135.65/µL (45–64 years), 67.95/µL (65–74 years), and 96.5/µL (≥75 years). B-A-C and WBC counts differed among the three most frequently identified bacteria (Escherichia coli, Klebsiella pneumoniae, and Enterococcus faecalis). The UF-1000i system is useful for applying age-specific cutoffs to screen for UTIs, thereby preventing antibiotic abuse and reducing antibiotic resistance. Future studies can explore how its B-A-C and WBC counts can facilitate selection of empirical antibiotics by distinguishing between gram-positive and gram-negative bacteria.

Key Words: UF-1000i, Urinary tract infection, Age-specific cutoff, Outpatients

Urinary tract infections (UTIs) are the most common bacterial infection worldwide, affecting 150 million people annually [1]. Most UTIs occur in outpatients, and outpatients with UTIs (8.6 million each year) account for most of the outpatients in the United States [2]. UTI prevalence varies across age groups [3]; however, its prevalence by age group in Korea is yet to be thoroughly investigated [4, 5].

The diagnostic gold standard for UTIs is urine culture to confirm the presence of bacteria, which takes a minimum of two days. Consequently, empirical antibiotics are typically prescribed for most patients before diagnosis, which increases antibiotic use and resistance [6].

Various alternatives to urine culture, such as dipstick urinalysis, microscopic sediment urinalysis, and automated urinalysis, are used to screen for UTIs. Dipstick urinalysis identifies nitrates and leukocyte esterase in urine. Its sensitivity and specificity were 75% and 82%, respectively, when nitrite or leukocyte esterase positive results are obtained [7]. Microscopic sediment urinalysis aids in UTI diagnosis by identifying bacteria (B-A-C) or white blood cells (WBC). Its sensitivity and specificity were 68.2% and 87.8%, respectively, when pyuria is present during UTI diagnosis [7], and 78.8% and 97.8%, respectively, when confirmed by bacteriuria [8]. Both dipstick urinalysis and microscopic sediment urinalysis are time-consuming and labor-intensive, and their outcomes can be influenced by the technician. Thus, a method of automated urinalysis has emerged [9].
The UF-1000i system (Sysmex, Kobe, Japan) is a type of flow cytometer that combines the impedance method with the identification and quantification of microscopic materials suspended in the urine [10]. UF-1000i has the advantage of having a separate bacterial analysis channel. It can analyze 64,000 particles per sample within 50–75 seconds and analyze 80–100 urine samples per hour. Consequently, it would be appropriate for UTI screening for a high number of urine samples [11]. The default parameters for classifying UTIs, defined as >20 WBCs/μL combined with >50 B-A-C/μL, are not suitable for practical diagnosis. Although some studies have suggested a unified cutoff value for UTI diagnosis for specific ages [12-15], a useful cutoff value is yet to be determined. No studies in Korea have determined a UF-1000i cutoff.

We retrospectively reviewed medical records to evaluate the usefulness of age-specific cutoffs of UF-1000i for rapid screening of UTIs. Our study was approved by the Institutional Review Board of Chung-Ang University Hospital, Seoul, Korea (1802-005-16146). From January 2010 to December 2017, 7,443 urine samples were analyzed. They were obtained from 7,443 outpatients at Chung-Ang University Hospital, aged between 0.5 months and 103 years (4,023 males and 3,420 females). None had received antibiotics within the previous four weeks. Repeat visits of the same outpatients were excluded. Outpatients over 15 years were classified into five age groups (15–24 years, 25–44 years, 45–64 years, 65–74 years, and ≥75 years) on the basis of a previous study on UTI prevalence [3]. Outpatients younger than 15 years were classified into two groups (<4 years and 4–14 years) as samples were collected using a different method for those <4 years.

Samples were collected in a sterile container using the midstream clean catch method except for outpatients <4 years, for whom urine was collected using a sterile pouch [16, 17]. Samples were analyzed using UF-1000i and urine culture. The UF-1000i analysis was completed within 30 minutes of collection. When 0.8-mL urine samples are loaded on the UF-1000i system along with buffer and two polymethine dyes, the suspended particles in the urine are counted and classified as WBCs, red blood cells (RBCs), epithelial cells, crystals, casts, and B-A-C within one min. Urine culture was performed using a 1-µL loop to streak urine onto blood agar and MacConkey agar plates. The culture medium was inoculated within two hours and was analyzed following incubation at 37°C, 5% CO₂ for 24–48 hours.

Table 1. Strains identified in urine cultures

| Strain* | N | <4 | 4–14 | 15–24 | 25–44 | 45–64 | 65–74 | ≥75 |
|---------|---|-----|------|-------|-------|-------|-------|-----|
| Escherichia coli | 937 | 90 | 21 | 42 | 166 | 264 | 173 | 181 |
| Klebsiella pneumoniae | 86 | 17 | 1 | 1 | 7 | 14 | 17 | 29 |
| Enterococcus faecalis | 72 | 8 | 5 | 6 | 5 | 9 | 17 | 22 |
| Proteus mirabilis | 37 | 8 | 1 | 1 | 3 | 14 | 4 | 6 |
| Streptococcus agalactiae | 27 | - | - | 1 | 2 | 6 | 11 | 7 |
| Citrobacter freundii | 24 | 13 | - | - | - | 1 | 6 | 4 |
| Lactobacillus species | 23 | - | 1 | 3 | 15 | 4 | - | - |
| Pseudomonas aeruginosa | 22 | 1 | 2 | 1 | 2 | 3 | 5 | 3 |
| Coagulase negative Staphylococcus | 19 | 2 | 2 | 2 | 3 | 5 | 3 | 2 |
| Enterobacter aerogenes | 16 | 9 | - | - | 2 | 1 | 1 | 3 |
| Enterobacter cloacae | 13 | 5 | - | - | 1 | - | 1 | 6 |
| Staphylococcus aureus | 13 | 1 | - | - | 1 | 6 | 3 | 2 |
| Klebsiella oxytoca | 11 | 7 | - | - | - | - | - | - |
| Enterococcus faecium | 10 | 4 | - | 1 | 1 | - | 1 | 3 |
| Streptococcus viridans group | 10 | 2 | 1 | 1 | 1 | 2 | 3 | - |
| Gram-negative bacteria | 36 | 9 | 5 | 1 | 2 | 5 | 5 | 9 |
| Gram-positive bacteria | 42 | 4 | 3 | 1 | 13 | 12 | 4 | 5 |
| Total | 1,398 | 180 | 42 | 61 | 224 | 346 | 255 | 290 |

*Species with count <10 were grouped together.
greater than $10^5$ colony forming units (CFU)/mL, bacterial identification and antimicrobial susceptibility analysis was performed using a Vitek 2 system (BioMérieux Inc., Durham, NC, USA). WBC, B-A-C, and RBC counts from UF-1000i were compared with culture results.

Statistical analysis was performed using IBM SPSS Statistics for Windows, version 22.0 (IBM Corp., Armonk, NY, USA). Based on the culture results, we generated age-dependent ROC curves and compared them to determine the usefulness of UF-1000i and the cutoffs for each age group. We chose a cutoff with high sensitivity that represents the maximum sum of sensitivity and specificity. The most appropriate sensitivity was ≥90%, the minimum sensitivity was ≥70%, and the minimum specificity was ≥60%. Additional analyses were performed on the three most commonly identified strains in urine culture. The UF-1000i WBC, B-A-C, and RBC counts of each strain were expressed as medians. The Kruskal-Wallis test was used to determine whether they significantly differed among strains, and Mann-Whitney U test was used to compare them between pairs of strains. $P<0.05$ was considered statistically significant.

Of the 7,443 samples analyzed, 1,398 were culture positive, 5,774 were culture negative, and 271 were contaminated. Table 1 shows the bacterial species and the number of identified culture positive samples. In all age groups, the area under the curve (AUC) was highest for the sum of the WBC and B-A-C graphs (Fig. 1). The cutoffs of the sums of the WBC and B-A-C graphs in each age group were presented. The AUC for all groups over 15 years of age was >0.9 and with >90% sensitivity. The three most commonly identified strains in urine culture were *Escherichia coli* (937 samples), *Klebsiella pneumoniae* (86 samples), and *Enterococcus faecalis* (72 samples). *E. coli* and *K. pneumoniae* infections resulted in higher B-A-C and WBC counts than *E. faecalis* infections (Fig. 2). Post-hoc analyses showed the following: *E. coli* vs *E. faecalis* (WBC $P<0.001$, B-A-C $P<0.001$, RBC $P=0.818$), *E. faecalis* vs *K. pneumoniae* (WBC $P=0.011$, B-A-C $P<0.001$, RBC $P=0.065$), and *E. coli* vs *K. pneumoniae* (WBC $P=0.577$, B-A-C $P=0.752$, RBC $P=0.063$).

Our results showed that UF-1000i is suitable for UTI screening in outpatients ≥15 years but not in outpatients <15 years.

Rapid screening of UTI by Sysmex UF-1000i

Fig. 2. Graph of median WBC vs B-A-C counts determined by UF-1000i (Sysmex, Kobe, Japan) in outpatients with a urinary tract infection confirmed to be caused by Escherichia coli (937 samples), Klebsiella pneumoniae (86 samples), and Enterococcus faecalis (72 samples). The distribution range (95% confidence interval, minimum, maximum, interquartile range) is as follows: E. coli B-A-C (11,765.0-14,186.4/µL, 2.0/µL, 99,086.0/µL, 17,826.1/µL), E. coli WBC (1.073.3-1,464.4/µL, 0.0/µL, 32,723.0/µL, 1,007.4/µL); E. faecalis B-A-C (1,836.6-5,964.5/µL, 0.0/µL, 53,597.0/µL, 3,016.4/µL), E. faecalis WBC (285.4-847.1/µL, 1.0/µL, 6,779.0/µL, 332.6/µL); K. pneumoniae B-A-C (10,532.2-18,205.2/µL, 2.0/µL, 80,533.0/µL, 20,834.0/µL), and K. pneumoniae WBC (582.3-2,037.0/µL, 1.0/µL, 31,392.0/µL, 1,081.3/µL).
