Abstract

Low-grade appendiceal mucinous neoplasm (LAMN) is a rare disease. The strategy of treatment for LAMN has not been established. We herein present a case of LAMN treated by laparoscopic ileocecal resection with D2 lymph node (LN) dissection, which exhibited invagination. A 59-year-old man visited at our emergency room with intermittent abdominal pain. Abdomino-pelvic computed tomography (CT) revealed suspiciously a diagnosis as intussusception of LAMN into the ascending colon. Emergency laparoscopic operation was performed. A laparoscopic ileocecal resection with D2 LN dissection was performed because swollen lymph nodes were notified around the ileocolic artery. Histologically, he was diagnosed as LAMN, T3, N0, M0, Stage II.

Keywords: Low-grade appendiceal mucinous neoplasm, Intussusception, Laparoscopic surgery

Introduction

The concept of low-grade appendiceal mucinous neoplasm (LAMN) is consistent with the recent edition of the World Health Organization (WHO) classification as one of appendiceal neoplasms, because of aggressive biological potential despite with a benign morphologic appearance1. In Japan, it has been recognized as a tumor equivalent to borderline malignancy, however it has been newly classified in the 8th edition of Japanese Classification of Colorectal Carcinoma2. Little evidence is known in terms of treatment strategy for LAMN because of few reports of analyses using accumulated data3.

We herein report a case of LAMN underwent laparoscopic ileocecal resection with lymphadenectomy as an equivalent to cancer after diagnosis due to intussusception.

Case report

A 59-year-old man who had been aware of intermittent abdominal pain in 3 days visited at our emergency room. He had no problems with his daily life. On arrival, his vital sign was stable. His physical findings showed that spontaneous pain and tenderness were obtained from the epigastric region to the right flank. No abnormal findings in his hematologic and chemical examination. Abdomino-pelvic computed tomography (CT) revealed a 4 cm-sized cystic tumor in the appendix with a uniform low density inverted into the ascending colon (Fig. 1). Emergency operation was scheduled under diagnosis as intussusception of LAMN into the ascending colon. Under general anesthesia, laparoscopic operation was performed using 5 ports. Laparoscopic ileocecal resection with D2 LN dissection was performed because swollen lymph nodes were notified around the ileocolic artery. Histologically, he was diagnosed as LAMN, T3, N0, M0, Stage II. Since his postoperative course was uneventful, he...
LAMN performed with laparoscopic surgery

discharged on postoperative day 8. Surveillance has been scheduled for Stage II colon cancer based on Japanese Society for Cancer of the Colon and Rectum (JSCCR) guidelines 2016 for the treatment of colorectal cancer. There is no symptom of relapse 15 months passed after surgery.

**Fig. 1.** CT scan revealed a 4 cm-sized cystic tumor in the appendix with a uniform low density (white arrow). It inverted into the ascending colon (white arrow head).

**Fig. 2.** Laparoscopic view revealed a marked swelling of the appendix was observed (white arrow) however intussusception had been already resolved.

**Fig. 3.** A swollen appendix had excluded the cecal wall (white arrow) macroscopically.

**Fig. 4.** A part of the epithelium fell off and was replaced by macrophages (a). An accumulated mucus was in contact with the muscle layers of cecum (white arrow: b).
Discussion

The appearance of LAMN is commonly an appendiceal mucocoele, which is characterized by the large amount of mucin in the appendiceal lumen. In LAMN, acellular mucin only beyond muscularis propria rarely has a recurrence risk. However, the potential to develop a malignant condition is increased in patients with positive margin; appendiceal rupture; mucin, cells, or both outside the appendix; or pseudomyxoma peritonei (5–8). Since cellular or acellular LAMN beyond muscularis propria should be already staged T3 category, careful attention should be needed in surgical procedure.

In this case, he was suspiciously diagnosed as LAMN with intussusception by the CT scan. Thereafter, an emergency operation was scheduled using laparoscopy. Under laparoscopic observation, he underwent laparoscopic ileocecal resection with D2 lymphadenectomy because of being observed an enlarged node belong to ileocolic vessels. Surgical resection is considered as the only curative treatment for LAMN. However, no definitive criterion for resection range is still unestablished. An appendectomy is enough for curative resection when the appendiceal root is intact (9). In the case of appendiceal mucinous adenocarcinoma, appendectomy could not be enough even when the appendiceal root is intact. The incidence of LN metastasis has been reported in 1.7% cases (10). Since cellular or acellular LAMN beyond muscularis propria is intact (9), when the appendiceal root is intact. The incidence of LN metastasis has been reported in 1.7% cases (10); however, that of mutinous adenocarcinoma ranging from 25 to 50% (11) and preoperative definitive diagnosis may be difficult (12). Therefore, ileocecal resection or right hemicolectomy with LN dissection is often performed. Analyses have been providing to clarify the clinicopathology of appendiceal cancer in a project study of the Japanese Society for Cancer of the Colon and Rectum. A treatment strategy will possibly be indicated based on their results.
