Technical Note

Mineral Detection Using Sharpened VNIR and SWIR Bands of Worldview-3 Satellite Imagery

Honglyun Park 1 and Jaewan Choi 2,*

Abstract: Worldview-3 satellite imagery provides panchromatic images with a high spatial resolution and visible near infrared (VNIR) and shortwave infrared (SWIR) bands with a low spatial resolution. These images can be used for various applications such as environmental analysis, urban monitoring and surveying for sustainability. In this study, mineral detection was performed using Worldview-3 satellite imagery. A pansharpening technique was applied to the spatial resolution of the panchromatic image to effectively utilize the VNIR and SWIR bands of Worldview-3 satellite imagery. The following representative similarity analysis techniques were implemented for the mineral detection: the spectral angle mapper (SAM), spectral information divergence (SID) and the normalized spectral similarity score ($NS_2^3$). In addition, pixels that could be estimated to indicate minerals were calculated by applying an empirical threshold to each similarity analysis result. A majority voting technique was applied to the results of each similarity analysis and pixels estimated to indicate minerals were finally selected. The results of each similarity analysis were compared to evaluate the accuracy of the proposed methods. From that comparison, it could be confirmed that false negative and false positive rates decreased when the methods proposed in the present study were applied.

Keywords: image fusion; Worldview-3; shortwave infrared; spectral angle mapper; mineral detection

1. Introduction

As satellite sensor technology advances, the spatial resolution of satellite images is being continuously improved and satellite sensors capable of acquiring diverse spectral wavelength bands have been recently developed. Satellite sensors are able to provide satellite images with diverse spatial and spectral resolutions. These can be utilized in the field, for example, in national environmental analyses, urban monitoring, change detection and surveying for sustainability [1]. In particular, Worldview-3 satellite images provide panchromatic images, eight visible near infrared (VNIR) bands and eight shortwave infrared (SWIR) bands with spatial resolutions of 0.3 m, 1.2 m and 3.7 m, respectively, and are known to be effective for the analysis of the properties of artificial structures, minerals and rocks as VNIR and SWIR bands between the spectral wavelength bands of 400 and 2,400 nm are provided [2,3]. However, as the spatial resolution of each band varies, the spatial resolution should be matched to utilize the satellite images for analysis [4]. Generally, images of a high spatial resolution are downsampled to match the image size of each band but this is disadvantageous because this reduces the utility of the images. Therefore, a pansharpening technique was developed to sharpen the VNIR and SWIR bands using the panchromatic band. Chavez et al. [5] developed the Brovey technique based on the ratio of the pixel value of the panchromatic band to the intensity of the image and Aiazzi et al. [6] proposed a sharpening technique using local coefficients to reduce the spatial distortion.

Target detection is a technique that analyzes the position of a pixel presumed to be a specific material by using the spectral properties of the pixels in remote sensing data [7–9]. A number of studies have recently been conducted related to target detection utilizing...
satellite images that provide wide wavelength bands such as Worldview-3 satellite images. Sun et al. [10] performed target detection for specific minerals using the band properties of Worldview-3 imagery and Le et al. [11] detected coal by applying an extreme learning machine to Landsat 8 OLI satellite images based on the spectral information of coal acquired using a spectroradiometer. Additionally, Kim [12] developed a processing technique to minimize the influence of background pixels on target detection using the matched filter (MF) and adaptive cosine estimator (ACE) techniques.

In this study, mineral detection was performed in areas that are difficult to access using satellite imagery. As the target area of this study is a region that cannot be accessed, the spectral data of minerals cannot be directly obtained. In this case, a method can be applied that uses the spectral data of pixels that are known to indicate the presence of minerals in the image. Mines and facilities near Pyeongsan (North Korea) were selected as the study area in this work. Worldview-3 satellite imagery, which provides VNIR and SWIR bands, was used for mineral detection and minerals were detected via a similarity analysis-based method using these VNIR and SWIR bands. To effectively utilize the VNIR and SWIR bands of Worldview-3, the VNIR and SWIR bands with a 0.3 m spatial resolution the same as that of a panchromatic image were produced by applying the pansharpening technique. Similarity analyses were conducted utilizing a spectral angle mapper (SAM), spectral information divergence (SID) and the normalized spectral similarity score (NS). Mineral-related spectral data were extracted from the Worldview-3 satellite images that had undergone a radiometric correction. The pixels presumed to be minerals were selected by applying thresholds to the results of the SAM, SID and NS methods and the final designation of the pixels (as indicating minerals or not) were determined by applying a majority voting method to the results from the three techniques. The accuracy of the method proposed in the present study was evaluated by comparing this final result with the individual results of applying SAM, SID and NS, respectively.

2. Methods

In this study, mineral detection was performed using the VNIR and SWIR bands of Worldview-3 satellites. Radiometric correction is essential when using satellite imagery for mineral detection. Therefore, radiometric correction was performed using the QUick Atmospheric Correction (QUAC) algorithm on the Worldview-3 satellite images. VNIR and SWIR bands with the same spatial resolution as the panchromatic image were produced by applying the GS2 (Gram–Schmidt 2) sharpening technique to the VNIR and SWIR bands. Similarity analyses were then conducted utilizing the spectral data of the minerals acquired from the Worldview-3 satellite images. The similarity analyses were conducted using SAM and SID and the pixels finally presumed to be minerals were determined by using a majority voting technique. The results obtained from this approach were comparatively evaluated with the respective results from the two similarity analyses to verify the performance of the method proposed in this study. Figure 1 shows the flowchart of the study.
Figure 1. Workflow of the proposed mineral detection.

2.1. Pansharpening

In general, a high-resolution satellite sensor provides high-resolution panchromatic images and low-resolution multispectral images. Panchromatic images and multispectral images are fused to produce high-resolution multispectral images, which increase the utility of the low-resolution images; this technique is called pansharpening. The pansharpening technique extracts high-frequency information from panchromatic images and injects this information into multispectral images [13–15] (see Equation (1)).

\[
\hat{\text{MS}}_n = \text{MS}_n + g_n (\text{P} - \text{IL}), \ n = 1, \ldots, N
\]

In Equation (1), \(\text{MS}_n\) is the sharpened high-resolution multispectral image, \(\text{MS}_n\) is the multispectral image interpolated using the scale of the P image, \(g_n\) is the injection gain, \(\text{P}\) is the panchromatic image, \(\text{IL}\) is the low-resolution synthetic intensity image and \(N\) represents the band number of the multispectral image.

The GS2 pansharpening technique was applied in this study. In the GS2 technique, the low-resolution images obtained by applying the image pyramid or image filtering technique to the panchromatic image are applied to \(\text{IL}\) (from Equation (1)). The variable \(g_n\) is calculated using the relation of the covariance between \(\text{IL}\) and the variance of \(\text{IL}\) [16].

2.2. Spectral Angle Mapper

In this study, similarity indexes were utilized for mineral detection. SAM measures similarities using the spectral angle between pixels [17,18]; see Equation (2).

\[
\text{SAM} = \cos \left( \frac{\langle V_1, V_2 \rangle}{\|V_1\| \|V_2\|} \right)
\]

In Equation (2), \(V_1\) and \(V_2\) refer to the pixels or spectral reflectances of the object and the material of interest, respectively, \(\langle V_1, V_2 \rangle\) is the inner product of the pixel values and \(\|V_1\|\) represents the size of the vector when the first pixel is assumed to be a vector. The SAM indexes are in the range of 0 to \(\pi/2\). The more similar the properties of pixels are to each other, the closer the value is to 0. As the SAM indexes measure the spectral angle of each pixel, materials that have different absolute values of spectral reflectance will have low values if they have the same spectral pattern.
2.3. Spectral Information Divergence

SID indexes are calculated assuming that each pixel of the object and the material of interest, \( p \) and \( q \), could be represented by random vectors. SID indexes can be put in order using Equation (3). Hence, the larger the value of the SID index, the higher the similarity between pixels [19,20].

\[
SID = \sum p \log \left( \frac{p}{q} \right) + \sum q \log \left( \frac{p}{q} \right)
\] (3)

2.4. Normalized Spectral Similarity Score

NS\(_3\) is one of the representative similarity analysis techniques and is defined as Equation (4).

\[
NS^3 = \sqrt{ED^2 + (1 - \cos \theta)^2}
\] (4)

In Equation (4), ED is the spectral distance between two pixels and \( \theta \) represents the spectral angle between two pixels. An NS\(_3\) index represents the average of the spectral angles and spectral distances and is a measure that quantifies the size difference, similarity and shape of the spectral reflectance [21,22]. NS\(_3\) indexes range from 0 to \( \sqrt{2} \). Hence, the closer the value is to 0, the higher the similarity between the pixels, as in the case of SAM.

3. Result and Discussion

3.1. Study Area and Materials

The VNIR and SWIR bands of Worldview-3 satellite images acquired on 17 October 2016 were utilized for mineral detection. The selected study area was Pyeongsan-gun (Hwanghaebuk-do, North Korea), which has regions in which uranium plants and mines are presumed to be located. The Worldview-3 satellite images utilized for mineral detection provided panchromatic images with a spatial resolution of 0.31 m, eight VNIR bands with a spatial resolution of 1.24 m and eight SWIR bands with a spatial resolution of 3.7 m. The panchromatic images were converted to a spatial resolution of 0.3 m through a geometric correction for use in the sharpening technique and the VNIR and SWIR bands were converted to spatial resolutions of 1.2 m and 3.7 m, respectively, which were integer multiples of the 0.3 m spatial resolution. In addition, a radiometric correction was used to transform the spectral reflectance values. Table 1 shows the spectral information for each band of the Worldview-3 satellite images and specifies the Worldview-3 satellite images utilized for the experiment, as shown in Figure 2.

Table 1. Worldview-3 data specifications.

| Worldview-3 Bands | Central Wavelength [nm] | Band Width [nm] | Spatial Resolution [m] |
|-------------------|-------------------------|----------------|-----------------------|
| Panchromatic      | 625                     | 350            | 0.31                  |
| Band 1: coastal   | 425                     | 50             |                       |
| Band 2: blue      | 480                     | 60             |                       |
| Band 3: green     | 545                     | 70             |                       |
| Band 4: yellow    | 605                     | 40             |                       |
| Band 5: red       | 660                     | 60             |                       |
| Band 6: red edge  | 725                     | 40             |                       |
| Band 7: near-IR 1 | 833                     | 125            |                       |
| Band 8: near-IR 2 | 950                     | 180            |                       |

| Band 16: SWIR 8   | 2330                   | 70             |                       |

Figure 2. Study area (Pyeongsan-gun, Hwanghaebuk-do, North Korea).

3.2. Experimental Results

As the target area of this study was an inaccessible region, mineral-related spectral data could not be directly obtained. In cases such as this, a method can be employed that uses the spectral data of pixels that are presumed to be pixels that solely indicate minerals in the image. Therefore, in this study, a spectral library was built using the spectral data of minerals acquired from Worldview-3 satellite images for mineral detection. The spectral data of the minerals were acquired from an area that was not included in Figure 2 and the average value of five pixels presumed to be pixels that only indicated minerals was ultimately designated as the spectral value of the mineral. The image of the region where the spectral data of the minerals were acquired is shown in Figure 3; this mine is known to produce the same mineral as the mine in Figure 2. Figure 4 is the spectral graph of the five pixels presumed to be the mineral.
A similarity analysis of the images of the study area was conducted using the previously built spectral library of the minerals. SAM, SID and NS$^3$ were applied in the similarity analyses and binary images were produced by applying empirical thresholds. Figure 5 shows the images before and after applying these thresholds to the results from the SAM, SID and NS$^3$ analyses.
A majority voting technique was applied to improve the accuracy of mineral detection. Majority voting was applied to pixels that were presumed to be minerals in each similarity analysis result. In majority voting, the pixels in which two or more results are estimated to be minerals as a result of applying three similarity techniques are finally determined to be mineral pixels.

The performance of the mineral detection method proposed in this study was both qualitatively and quantitatively evaluated and the object of comparison was the result of applying each similarity analysis. The qualitative evaluation involved a visual reading of the images and the quantitative evaluation entailed calculating the confusion matrix using ground truth data. Ground truth data were obtained from pixels known to indicate minerals in the image of the study area. Figure 6 shows the majority voting results and Tables 2–5 show the results of the quantitative evaluation.
Figure 6. Results of applying the majority voting method: (a) ground truth image and (b) final mineral detection result.

Table 2. Result of mineral detection by applying SAM.

| Ground Truth Data                  | Mineral pixels | Non-mineral pixels |
|-----------------------------------|----------------|-------------------|
| Mineral pixels                    | 223,118        | 152,424           |
| Non-mineral pixels                | 29,880         | 13,594,578        |
| Detection rate                    | 0.882          |                   |
| False alarm rate                  | 0.011          |                   |

Table 3. Result of mineral detection by applying SID.

| Ground Truth Data                  | Mineral pixels | Non-mineral pixels |
|-----------------------------------|----------------|-------------------|
| Mineral pixels                    | 131,586        | 21,315            |
| Non-mineral pixels                | 121,412        | 13,725,687        |
| Detection rate                    | 0.520          |                   |
| False alarm rate                  | 0.002          |                   |
Table 4. Result of mineral detection by applying NS\textsuperscript{3}.

| Mineral detection result using NS\textsuperscript{3} | Ground Truth Data |       |       |
|-----------------------------------------------------|-------------------|-------|-------|
|                                                     | Mineral pixels    | Non-mineral pixels |
| MINERAL pixels                                      | 205,683           | 264,826 |
| NON-MINERAL pixels                                  | 47,315            | 13,482,176 |
| Detection rate                                      | 0.813             |       |
| False alarm rate                                    | 0.019             |       |

Table 5. Result of mineral detection by applying majority voting.

| Mineral detection result using majority voting | Ground Truth Data |       |       |
|------------------------------------------------|-------------------|-------|-------|
|                                                     | Mineral pixels    | Non-mineral pixels |
| MINERAL pixels                                      | 203,291           | 60,480 |
| NON-MINERAL pixels                                  | 49,707            | 13,686,522 |
| Detection rate                                      | 0.804             |       |
| False alarm rate                                    | 0.004             |       |

The qualitative evaluation confirmed that the proportion of undetected areas and the false alarm rate were lower than the results obtained by individually conducting each similarity analysis. In particular, the false alarm rate of water-covered areas and building shadows, which show a low spectral reflectance (like minerals) decreased. The results from the quantitative evaluation were similar to the qualitative evaluation results. The detection accuracy for the SAM and NS\textsuperscript{3} results were 0.882 and 0.813, respectively, showing high detection rates. However, the false alarm rates were also high at 0.011 and 0.019, respectively, indicating overdetection. The false alarm rate was low (0.002) for the SID result but the detection rate was also low (0.520). The detection rate of the method proposed in this study was 0.804, which was slightly lower than the SAM and NS\textsuperscript{3} detection rates but the false alarm rate was greatly reduced (0.004). This confirmed that the method proposed in this study produced high detection rates and low false detection rates.

4. Conclusions

The VNIR and SWIR bands from Worldview-3 satellite imagery were used for mineral detection in this study. As part of our approach, the low-resolution VNIR and SWIR bands were converted to high-resolution bands through the GS2 method. In addition, a spectral library of the target minerals was constructed for detection and the spectral data of the target minerals were computed as the average of five pixels in the images estimated to be purely composed of the target mineral. SAM, SID and NS\textsuperscript{3}, which are representative similarity analysis techniques, were used for mineral detection and binary images of pixels presumed to be minerals were produced by applying an empirical threshold to the results of the similarity analyses. Majority voting was then used to determine the final mineral designation of a given pixel when the results of more than two of the three similarity analyses determined that the pixel indicated the presence of a mineral. The proposed method was evaluated by a comparison with the results of each similarity analysis and it was confirmed that the detection rate increased by 28% when compared with the SID results and false alarms decreased by 1.5% when compared with the NS\textsuperscript{3} results. Further mineral detection research is planned by acquiring verified spectral data for minerals.
