(Received 29 April 2008; published 2 September 2008)

We explore the subtle relationships between partial separability and entanglement of subsystems in multiqubit quantum states and give experimentally accessible conditions that distinguish between various classes and levels of partial separability in a hierarchical order. These conditions take the form of bounds on the correlations of locally orthogonal observables. Violations of such inequalities give strong sufficient criteria for various forms of partial inseparability and multiqubit entanglement. The strength of these criteria is illustrated by showing that they are stronger than several other well-known entanglement criteria (the fidelity criterion, violation of Mermin-type separability inequalities, the Laskowski-Zukowski criterion, and the Dür-Cirac condition) and also by showing their great noise robustness for a variety of multiqubit states, including N-qubit Greenberger-Horne-Zeilinger states and Dicke states. Furthermore, for N≥3 they can detect bound entangled states. For all these states, the required number of measurement settings for implementation of the entanglement criteria is shown to be only N+1. If one chooses the familiar Pauli matrices as single-qubit observables, the inequalities take the form of bounds on the antidiagonal matrix elements of a state in terms of its diagonal matrix elements.

I. INTRODUCTION

The problem of characterizing entanglement for multipartite quantum systems has recently drawn much attention. An important issue in this problem is that, apart from the extreme cases of full separability and full entanglement of all particles in the system, one also has to face the intermediate cases in which only some particles in the system are entangled and others not. The latter states are usually called “partially separable” or, more precisely, “k-separable” when they take the form of a mixture of states that factorize when the N-partite system is partitioned into k subsystems (k≤N) [1–4]. In this paper we will focus on multiqubit systems only. We propose a classification of partially separable states for such systems, slightly extending the classification introduced by Dür and Cirac [2]. This classification consists of a hierarchy of levels corresponding to the k-separable states for k=1,…,N, and within each level various classes are distinguished by specifying under which partitions of the system the state is separable or not.

Several experimentally accessible conditions to characterize k-separable multiqubit states have already been proposed, e.g., by Laskowski and Zukowski [5], Mermin-type separability inequalities [1,6–10], or in terms of entanglement witnesses [11]. However, these conditions do not distinguish the various classes within the levels. Separability conditions that do distinguish some of these classes in the hierarchy were developed by Dür and Cirac. Here we present separability conditions that extend and strengthen all the conditions just mentioned.

These conditions take the form of sets of inequalities that bound the correlations for standard Bell-type experiments (involving at each site measurement of two orthogonal spin observables). They form a hierarchy with bounds that decrease by a factor of 4 for each level k in the partial separability hierarchy. For the classes within a given level, the inequalities give state-dependent bounds, differing for each class. Violations of the inequalities provide strong sufficient criteria for various forms of inseparability and multiqubit entanglement.

We demonstrate the strength of these conditions in two ways: First, by showing that they imply several other general separability conditions, namely the fidelity criterion [12–14], the partial separability conditions just mentioned, i.e., the Laskowski-Zukowski condition (with a strict improvement for k=2, N), the Dür-Cirac condition, and the Mermin-type separability inequalities. We also show that the latter are equivalent to the Laskowski-Zukowski condition.

Second, we compare the conditions to other state-specific multiqubit entanglement criteria [11,15,16] both for their white noise robustness and for the number of measurement settings required in their implementation. In particular, we show (i) detection of bound entanglement for N≥3 with noise robustness for detecting the bound entangled states of Ref. [3] that goes to 1 for large N (i.e., maximal noise robustness), (ii) detection of the four qubit Dicke state with noise robustness 0.84 and 0.36 for detecting it as entangled and fully entangled, respectively, (iii) great noise and decoherence robustness [17,18] in detecting entanglement of the N-qubit Greenberger-Horne-Zeilinger (GHZ) state where for colored noise and for decoherence due to dephasing the robustness for detecting full entanglement goes to 1 for large N, and lastly, (iv) better white noise robustness than the stabilizer witness criteria of Ref. [11] for detecting the N-qubit GHZ states. In all these cases it is shown that only N+1 settings are needed.

Choosing the familiar Pauli matrices as the local orthogonal observables yields a convenient matrix element representation of the partial separability conditions. In this representation, the inequalities give specific bounds on the antidiagonal matrix elements in terms of the diagonal ones.

Further, some comments will be made along the way on how these results relate to the original purpose 19 of Bell-type inequalities to test local hidden-variable (LHV) models against quantum mechanics. Most notably, when the number of parties is increased, there is not only an exponentially increasing factor that separates the correlations allowed in maximally entangled states in comparison to those of local hidden-variable theories, but, surprisingly, also an exponentially increasing factor between the correlations allowed by LHV models and those allowed by nonentangled qubit states.

This paper is structured as follows. In Sec. II we define the relevant partial separability notions and extend the hierarchical partial separability classification of Ref. [2]. There we also introduce the notions of $k$-separable entanglement and of $m$-partite entanglement in order to investigate the relation between partial separability and multipartite entanglement. We then discuss four known partial separability conditions discussed above. In Sec. III we derive partial separability conditions for $N$ qubits in terms of locally orthogonal observables. They provide the desired necessary conditions for the full hierarchical separability classification. In Sec. IV the experimental strength of these criteria is discussed. We end in Sec. V with a discussion of the results obtained.

II. PARTIAL SEPARABILITY AND MULTIPARTITE ENTANGLEMENT

In this section we introduce terminology and definitions to be used in later sections. We define the notions of $k$-separability, $\alpha_k$-separability, $k$-separable entanglement, and $m$-partite entanglement and use these notions to capture aspects of the separability and entanglement structure in multipartite states. We review the separability hierarchy introduced by Dür and Cirac [2] and extend their classification. We also discuss four partial separability conditions known in the literature. These conditions will be strengthened in Sec. III.

A. Partial separability and the separability hierarchy

Consider an $N$-qubit system with Hilbert space \( \mathcal{H} = \mathbb{C}^2 \otimes \cdots \otimes \mathbb{C}^2 \). Let \( \alpha_i = (S_1, \ldots, S_j) \) denote a partition of \( \{1, \ldots, N\} \) into $j$ disjoint nonempty subsets \( (k \leq N) \). Such a partition corresponds to a division of the system into $k$ distinct subsystems, also called a $k$-partite split [2]. A quantum state $\rho$ of this $N$-qubit system is $k$-separable under a specific $k$-partite split $\alpha_k$ [1–4] if and only if it is fully separable in terms of the $k$ subsystems in this split, i.e., if and only if

$$
\rho = \sum_i p_i \otimes_{n=1}^k \rho_i^{s_i}, \quad p_i \geq 0, \quad \sum_i p_i = 1, \quad (1)
$$

where $\rho_i^{s_i}$ is a state of subsystem corresponding to $S_i$ in the split $\alpha_k$. We denote such states as $\rho \in D_N^{k\text{-sep}}$ and also call them $\alpha_k$-separable, for short. Clearly, $D_N^{k\text{-sep}}$ is a convex set. A state of the $N$-qubit system outside this set is called $\alpha_k$-inseparable.

More generally, a state $\rho$ is called $k$-separable [5,20–23] (denoted as $\rho \in D_N^{k\text{-sep}}$) if and only if there exists a convex decomposition

$$
\rho = \sum_j p_j \otimes_{n=1}^k \rho_j^{s_j}, \quad p_j \geq 0, \quad \sum_j p_j = 1, \quad (2)
$$

where each state $\otimes_{n=1}^k \rho_j^{s_j}$ is a tensor product of $k$ density matrices of the subsystems corresponding to some such partition $\alpha_k^{(j)}$, i.e., it factorizes under this split $\alpha_k^{(j)}$. In this definition, the partition may vary for each $j$, as long as it is a $k$-partite split, i.e., contains $k$ disjoint nonempty sets. Clearly $D_N^{k\text{-sep}}$ is also convex; it is the convex hull of the union of all $D_N^{k\text{-sep}}$ for fixed values of $k$ and $N$. States that are not $k$-separable will be called $k$-inseparable. Note that a $k$-separable state need not be $\alpha_k$-separable for any particular split $\alpha_k$ [24]; and even the converse implication need not hold: If a state is biseparable under every bipartition, it does not have to be fully separable, as shown by the three-partite examples in Ref. [25]. Similar observations (using different terminology) were presented in Refs. [20,21], but below we will present a more systematic investigation.

The notion of $k$-separability naturally induces a hierarchical ordering of the $N$-qubit states. Indeed, the sequence of sets $D_N^{k\text{-sep}}$ is nested: $D_N^{k\text{-sep}} \subset D_N^{k+1\text{-sep}} \subset \cdots \subset D_N^{N\text{-sep}}$. In other words, $k$-separability implies $\ell$-separability for all $\ell \leq k$. We call a $k$-separable state that is not $(k+1)$-separable "$k$-separably entangled." Thus each $N$-qubit state can be characterized by the level $k$ for which it is $k$-separably entangled, and these levels provide a hierarchical ranking: at one extreme end are the 1-separable entangled states which are fully entangled (e.g., the GHZ states), at the other end are the $N$-separable or fully separable states (e.g., product states or the "white noise state" 1/2$^N$).

Often, it is interesting to know how many qubits are entangled in a $k$-separable entangled state. However, this question does not have a unique answer. For example, take $N = 4$ and $k=2$ (biseparability). In this case two types of states may occur in the decomposition (2), namely $\rho^{(i)} \otimes \rho^{(j)}$ and $\rho^{(i)} \otimes \rho^{(j,k,l)} (i,j,k,l=1,2,3,4)$. A 2-separable entangled four-partite state might thus be two- or three-partite entangled.

In general, an $N$-qubit state $\rho$ will be called "$m$-partite entangled" if and only if a decomposition of the state such as in Eq. (2) exists such that each subset $S^{(i)}$ contains at most $m$ parties, but no such decomposition is possible when all the $k$ subsets are required to contain less than $m$ parties [13]. [In Refs. [20,21] this is called "not producible by $(m-1)$-partite entanglement."] It follows that a $k$-separable entangled state is also $m$-partite entangled, with $[N/k] \leq m \leq N-k+1$. Here $[N/k]$ denotes the smallest integer which is not less than $N/k$. Thus a state that is $k$-separably entangled ($k < N$) is at least $[N/k]$-partite entangled and might be up to $(N-k+1)$-partite entangled. Therefore conditions that distinguish $k$-separability from $(k+1)$-separability also provide conditions for $m$-partite entanglement, but generally allowing a wide range of values of $m$. For example, for $N=100$ and $k = 2$, $m$ might lie anywhere between 50 and 99.

Of course, a much tighter conclusion about $m$-partite entanglement can be drawn if we know exactly under which splits the state is separable. This is why the notion of $\alpha_k$-separability is helpful, since it provides these finer distinctions. For example, suppose that a 100-qubit state is separable under the bipartite split (\{(1,2,\ldots,100)\}) but under
no other bipartite split. This state would then be 2-separable (biseparable) but now we could also infer that $m=99$. On the other hand, if the state were only separable under the split $[(1, ..., 50), (51, ..., 100)]$, it would still be biseparable, but only $m$-partite entangled for $m=50$.

Dür and Cirac [2] provided such a fine-grained classification of $N$-qubit states by considering their separability or inseparability under all $k$-partite splits. Let us introduce this classification (with a slight extension) by means of the example of three qubits, labeled as $a,b,c$.

**Class 3.** Starting with the lowest level $k=3$, there is only one 3-partite split, $a-b-c$, and consequently only one class to be distinguished at this level, i.e., $D_{3}^{a b c}$. This set coincides with $D_{3}^{3}$-sep-

**Classes 2.1–2.8.** Next, at level $k=2$, there are three bipartite splits: $a-(b,c)$, $b-(a,c)$, and $c-(a,b)$ which define the sets $D_{2}^{a-(b,c)}$, $D_{2}^{b-(a,c)}$, and $D_{2}^{c-(a,b)}$. One can further distinguish classes defined by all logical combinations of separability and inseparability under these splits, i.e., all the set-theoretical intersections and complements shown in Fig. 1. This leads to classes 2.2–2.8. Dür and Cirac showed that all these classes are nonempty. To these, we add one more class 2.1: the set of biseparable states that are not separable under any split. As we have seen, this set is nonempty too.

**Class 1.** Finally, at level $k=1$ there is again only one (trivial) split $(a,b,c)$, and thus only one class, consisting of all the fully entangled states, i.e., $D_{1}^{abc} \setminus D_{2}^{a b c}$.

We feel that the above extension is desirable since otherwise the Dür-Cirac classification would not distinguish between class 2.1 and class 1. However, states in class 2.1 are simply convex combinations of states that are biseparable under different bipartite splits. Such states can be realized by mixing the biseparable states and are conceptually different from the fully inseparable states of class 1.

This three-partite example serves to illustrate how the Dür-Cirac separability classification works for general $N$.

Level $k$ ($1 \leq k \leq N$) of the separability hierarchy consists of all $k$-separable entangled states. Each level is further divided into distinct classes by considering all logically possible combinations of separability and inseparability under the various $k$-partite splits. The number of such classes increases rapidly with $N$, and therefore we will not attempt to list them. In general, all such classes may be nonempty. As an extension of the Dür-Cirac classification, we distinguish at each level $1 < k < N$ one further class, consisting of $k$-separable entangled states that are not separable under any $k$-partite split.

In order to find relations between these classes, the notion of a contained split is useful [2]. A $k$-partite split $\alpha_{k}$ is contained in a $\ell$-partite split $\alpha_{\ell}$, denoted as $\alpha_{k} < \alpha_{\ell}$, if $\alpha_{k}$ can be obtained from $\alpha_{\ell}$ by joining some of the subsets of $\alpha_{\ell}$. The relation $<$ defines a partial order between splits at different levels. This partial order is helpful because $\alpha_{k}$-separability implies $\alpha_{\ell}$-separability of all splits $\alpha_{i}$ containing $\alpha_{k}$. We will use this implication below to obtain conditions for separability of a $k$-partite split at level $k$ from such conditions on all $(k-1)$-partite splits at level $k-1$. This $k$-partite split is contained in. At Conditions at a lower level thus imply conditions at a higher level.

The multipartite entanglement properties of $k$-separable or $\alpha_{k}$-separable states are subtle, as can be seen from the following examples.

(i) Mixing states does not conserve $m$-partite entanglement. Take $N=3$, then mixing the 2-partite entangled 2-separable states $(|0\rangle \otimes (|00\rangle + |11\rangle)) / \sqrt{2}$ and $(|0\rangle \otimes ((|00\rangle - |11\rangle)) / \sqrt{2}$ with equal weights gives a 3-separable state $(|000\rangle (|000\rangle + |011\rangle)) / \sqrt{2}$.

(ii) An $N$-partite state can be $m$-partite entangled ($m < N$) even if it has no $m$-partite subsystem whose (reduced) state is $m$-partite entangled [13,20]. Such states are said to have irreducible $m$-partite entanglement [26]. Thus a state of which some reduced state is $m$-partite entangled is itself at least $m$-partite entangled, but the converse need not be true.

(iii) Consider a biseparable entangled state that is only separable under the bipartite split $((1),(2,\ldots,N))$. One cannot infer that the subsystem $\{2,\ldots,N\}$ is ($N-1$)-partite entangled. A counterexample is the three-qubit state $\rho = (|0\rangle \langle 0| \otimes P_{bc}^{(b,c)} + |1\rangle \langle 1| \otimes P_{bc}^{(b,c)}) / 2$ which is biseparable only under the partition $a-(b,c)$, and thus bipartite entangled, but has no bipartite subsystem whose reduced state is entangled. Here $P_{bc}^{(b,c)}$ and $P_{bc}^{(b,c)}$ denote projectors on the Bell states $|\phi^{-}\rangle = \frac{1}{\sqrt{2}} (|01\rangle - |10\rangle)$ for parties $b$ and $c$, respectively.

(iv) A state that is inseparable under all splits but which is not fully inseparable (i.e., $\rho \in D_{N}^{k=sep}$ with $k>1$ and $\rho \notin \bigcup_{\alpha_{k}} D_{N}^{\alpha_{k}} \forall \alpha_{k}, k$) might still have all forms of $m$-partite entanglement apart from full entanglement, i.e., it could be $m$-partite entangled with $2 \leq m \leq N-1$. Thus the state could even have $m$-partite entanglement as low as 2-partite entanglement, although it is inseparable under all splits. For example, Töth and Gühne [21] consider a mixture of two $N$-partite states where each of them is $(N/2)$-separable according to different splits. This mixed state is by construction $(|N/2\rangle\rangle$-separable, not biseparable under any split, yet only 2-partite entangled. See also the example in [24] which is
(N−1)-separable and only 2-partite entangled.

(v) Lastly, N-partite fully entangled states exist where no m-partite reduced state is entangled (such as N-qubit GHZ state) and also where all m-partite reduced states are entangled (such as the N-qubit W states) [27].

These examples serve to emphasize that one should be very cautious in inferring the existence of entanglement in subsystems of a larger system which is known to be m-partite entangled or k-separable entangled for some specific value of m and k.

**B. Separability conditions**

We now review four separability conditions for qubits, which will all be strengthened in the next section. These are necessary conditions for states to be k-separable, 2-separable, and $\alpha_2$-separable, respectively.

1) Laskowski and Żukowski [5] showed that for any k-partite N-qubit state $\rho$ the antidiagonal matrix elements (denoted by $|j, j\rangle$, where $j = d + 1 - j$, $d = 2^N$) must satisfy

$$\max_j |\rho_{jj}| \leq \left(\frac{1}{2}\right)^k, \quad \forall \rho \in D_N^{2\text{-sep.}}. \quad (3)$$

This condition can be easily proven by the observation that for any density matrix to be physically meaningful its antidiagonal matrix elements must not exceed 1/2. Therefore antidiagonal elements of a product of k density matrices cannot be greater than $(1/2)^k$. By convexity, this results then holds all k-separable states. Note that this condition is not basis dependent.

It follows from Eq. (3) that if the antidiagonal matrix elements of state $\rho$ obey

$$\left(\frac{1}{2}\right)^k \geq \max_j |\rho_{jj}| > \left(\frac{1}{2}\right)^{k+1}, \quad (4)$$

then $\rho$ is at most k-separable, i.e., k-separable entangled, and thus at least m-partite entangled, with $m \geq [N/k]$. The partial separability condition (3) does not yet explicitly refer to directly experimentally accessible quantities. However, in the next section we will rewrite this condition in terms of expectation values of local observables and show that they are equivalent to Mermin-type separability inequalities.

2) Mermin-type separability inequalities [1,6,8–10]. Consider the familiar Clauser-Horne-Shimony-Holt operator for two qubits (labeled as a and b) which is defined by

$$M^{(2)} := X_a \otimes X_b + X_a \otimes Y_b + Y_a \otimes X_b - Y_a \otimes Y_b. \quad (5)$$

Here, $X_a$ and $Y_a$ denote two spin observables on the Hilbert spaces $H_a$ and $H_b$ of qubit a and b. The so-called Mermin operator [28] is a generalization of this operator to N qubits [labeled as (a, b, ...., n)], defined by the recursive relation

$$M^{(N)} := \frac{1}{2} M^{(N-1)} \otimes (X_a + Y_a) + \frac{1}{2} M^{(N-1)} \otimes (X_a - Y_a), \quad (6)$$

where $M'$ is the same operator as $M$ but with all X’s and Y’s interchanged.

In the special case where, for each qubit, the spin observables $X$ and $Y$ are orthogonal, i.e., $\{X_i, Y_i\} = 0$ for $i \in \{a, ..., n\}$, Nagata et al. [1] obtained the following k-separability conditions:

$$\langle M^{(N)} \rangle^2 + \langle M^{(N)} \rangle^2 \leq 2^N \langle \frac{1}{4} \rangle^k, \quad \forall \rho \in D_N^{k\text{-sep.}}. \quad (7)$$

As just mentioned, the next section will show that these inequalities are equivalent to the Laskowski-Żukowski inequalities. The quadratic inequalities (7) also imply the following sharp linear Mermin-type inequality for k-separability:

$$\langle \langle M^{(N)} \rangle \rangle^2 \leq 2^{N+1} \langle \frac{1}{2} \rangle^k, \quad \forall \rho \in D_N^{k\text{-sep.}}. \quad (8)$$

For $k = N$ inequality (8) reproduces a result obtained by Roy [10].

3) The fidelity $F(\rho)$ of a N-qubit state $\rho$ with respect to the generalized N-qubit GHZ state $|\Psi_N^{GHZ,\alpha}\rangle := ((0)^{\otimes N} + e^{i\alpha}|1)^{\otimes N}/\sqrt{2} (\alpha \in \mathbb{R}$) is defined as

$$F(\rho) := \max_a \langle \Psi_N^{GHZ,\alpha}\rangle |\rho N^{GHZ,\alpha}\rangle = \frac{1}{2} (\rho_{1,1} + \rho_{d,d}) + |\rho_{1,d}|, \quad (9)$$

The fidelity condition [12–14] (also known as the projection-based witness [11]) says that for all biseparable $\rho$,

$$F(\rho) \leq 1/2, \quad \forall \rho \in D_N^{2\text{-sep.}}. \quad (10)$$

In other words, $F(\rho) > 1/2$ is a sufficient condition for full N-partite entanglement. An equivalent formulation of Eq. (10) is

$$2|\rho_{1,d}| \leq \sum_{j \neq 1,d} |\rho_{j,j}|, \quad \forall \rho \in D_N^{2\text{-sep.}}. \quad (11)$$

Of course, analogous conditions may be obtained by replacing $|\Psi_N^{GHZ,\alpha}\rangle$ in the definition (9) by any other maximally entangled state [14,29]. Exploiting this feature, one can reformulate Eq. (11) in a basis-independent form:

$$2 \max_{j \neq 1,d} |\rho_{j,j}| \leq \sum_{j \neq 1,d} |\rho_{j,j}|, \quad \forall \rho \in D_N^{2\text{-sep.}}. \quad (12)$$

Note that in contrast to the Laskowski-Żukowski condition and the Mermin-type separability inequalities, the fidelity condition does not distinguish biseparability and other forms of k-separability. Indeed, a fully separable state (e.g., $|0)^{\otimes N}$) can already attain the value $F(\rho) = 1/2$. Thus the fidelity condition only distinguishes full inseparability (i.e., $k = 1$) from other types of separability ($k \geq 2$). However, as will be shown in the next section, violation of the fidelity condition yields a stronger test for full entanglement than violation of the Laskowski-Żukowski condition.

4) The Dür-Cirac depolarization method [2,4] gives necessary conditions for partial separability under specific bipartite splits. It uses a two-step procedure in which a general state $\rho$ is first depolarized to become a member of a special family of states, called $\rho_\alpha$, after which this depolarized state is tested for $\alpha_2$-separability under a bipartite split $\alpha_2$. If the
depolarized state $\rho_{ij}$ is not separable under $c_{ij}$, then neither is the original state $\rho$, but not necessarily vice versa since the depolarization process can decrease inseparability.

The special family of states $\rho_N$ is given by

$$\rho_N = \lambda_0^N |\psi_0^N(\phi_0^N) + \lambda_0^N |\psi_0(\phi_0)| + \sum_{j=1}^{2^{N-1}} \lambda_j (|\psi_j^N(\phi_j^N) + |\psi_j(\phi_j)|),$$

(13)

with the so-called orthonormal GHZ-basis $|\phi_j^N\rangle = 1/\sqrt{2}(|j\rangle \pm |j^{1^c}\rangle)$, where $j = j_1j_2\cdots j_{N-1}$ is in binary notation (i.e., a string of $N-1$ bits), and $j^c$ means a bit-flip of $j$: $j^c = j_1^c j_2^c \cdots j_{N-1}^c$, with $j_i^c = 1,0$ if $j_i = 0,1$. The depolarization process does not alter the values of $\lambda_0^N = (\langle \phi_0^N|\rho|\phi_0^N\rangle)$ and of $\lambda_j = (\langle \phi_j^N|\rho|\phi_j^N\rangle + \langle \phi_j|\rho|\phi_j\rangle)/2$ of the original state $\rho$. The values of $j = j_1j_2\cdots j_{N-1}$ can be used to label the various bipartite splits by stipulating that $j = j_1j_2\cdots j_{N-1}$, $j_n = 0,1$ corresponds to the $n$th qubit belonging (not to) the same subset as the last qubit. For example, the splits $a-(bc)$, $b-(ac)$, $c-(ab)$ have labels $j = 10,01,11$, respectively.

The Dür-Cirac condition [2] says that a state $\rho$ is separable under a specific bipartite split $ij$ if

$$|\lambda_0^i - \lambda_0^j| \leq 2\lambda_j \Leftrightarrow 2|\rho_{ij,kl}| \leq \rho_{ij} + \rho_{kl},$$

(14)

For the states (13) this condition is in fact necessary and sufficient. In the right-hand side of the second inequality of Eq. (14) $l$ is determined from $j$ using $	ext{Tr}([\rho |\psi_j^N(\phi_j^N) + |\psi_j|\phi_j\rangle]) = \rho_{ij} + \rho_{kl}$.

Separability conditions for multipartite splits are constructed from the conditions (14) by means of the partial order $\prec$ of containment. As mentioned above, if a state is $\alpha_2$-separable, then it is also $\alpha_2$-separable for all bipartite splits $\alpha_2 < \alpha_2$. Therefore the conjunction of all $\alpha_2$-separability conditions must hold for such a state.

Note that if $|\lambda_0^i - \lambda_0^j| > 2\max_1 \lambda_j$, the state is inseparable under all bipartite splits, but this does not imply that it is fully inseparable (cf. [24]). Indeed, this feature also exists for states of the form (13) as the following example shows. Take the following two members of the family (13) for $N = 3$: for $\rho_1^i$ we choose $\lambda_0^0 = 1/2$, $\lambda_0^1 = 0$, $\lambda_1^1 = 1/4$, $\lambda_0^2 = 0$, and for $\rho_1^j$, $\lambda_0^1 = 1/2$, $\lambda_0^2 = 0$, $\lambda_1^0 = 0$, $\lambda_0^0 = 0$, $\lambda_1^1 = 1/4$. It follows from condition (14) that $\rho_1^i$ is separable under split $a-(bc)$ and inseparable under other splits, while $\rho_1^j$ is separable under the split $c-(ab)$ and inseparable under any other split. Now form a convex mixture of these two states: $\tilde{\rho}_1 = \alpha \rho_1^i + \beta \rho_1^j$ with $\alpha + \beta = 1$ and $\alpha, \beta \in (0,1)$. This state $\tilde{\rho}_1$ is still of the form (13), so that we can again apply condition (14) to conclude that $\tilde{\rho}_1$ is not separable under any bipartite split, yet inseparable by construction.

In the next section we give necessary conditions for $k$-separability and $\alpha_2$-separability that are stronger than the Laskowski-Żukowski condition (for $k = 2, N$), the fidelity condition, and the Dür-Cirac condition.

III. DERIVING PARTIAL SEPARABILITY CONDITIONS

This section presents separability conditions for all levels and classes in the separability hierarchy of $N$-qubit states. We start with the case of $N = 2$, which has been treated more extensively in [30]. We next move on to the slightly more complicated case of three qubits, for which explicit separability conditions are given for each of the ten classes in the separability hierarchy which were depicted in Fig. 1. Finally, the case of $N$ qubits is treated by a straightforward generalization.

A. Two-qubit case: Setting the stage

For two-qubit systems the separability hierarchy is very simple: there is only one possible split, and consequently just one class at each of the two levels $k = 1$ and $2$, i.e., states are either inseparable (entangled) or separable. Consider a system composed of a pair of qubits in the familiar setting of two distant sites, each receiving one of the two qubits, and where, at each site, a measurement of either of two spin observables is made. We will focus on the special case that these local spin observables are mutually orthogonal. Let $(X_a, Y_a, Z_a)$ denote three orthogonal spin observables on qubit $a$, and $(X_b, Y_b, Z_b)$ on qubit $b$. (The superscript $1$ denotes that we are dealing with single-qubit operators.) A familiar choice for the orthogonal triples $(X_1, Y_1, Z_1)$ are the Pauli matrices $(x_a, y_a, z_a)$; but note that the choice of the two sets need not coincide. We further define $I_{a,b}^{(1)} = 1$. For all single-qubit pure states $|\psi\rangle$ we have

$$\langle X_1^{(1)} \rangle_\psi + \langle Y_1^{(1)} \rangle_\psi + \langle Z_1^{(1)} \rangle_\psi = 1,$$

and for mixed states $\rho$

$$\langle X_1^{(1)} \rangle_\rho + \langle Y_1^{(1)} \rangle_\rho + \langle Z_1^{(1)} \rangle_\rho \leq 1,$$

(15)

(16)

We write $X_a X_b$ or even $XX$, etc. as shorthand for $X_a \otimes X_b$ and $(XX) := \text{Tr}[(\rho|X_a \otimes X_b)$ for the expectation value in a general state $\rho$, and $(XX) := \langle \psi|X_a \otimes X_b|\psi\rangle$ for the expectation in a pure state $|\psi\rangle$.

So, let two triples of locally orthogonal observables $(X_a, Y_a, Z_a)$ and $(X_b, Y_b, Z_b)$ be given, where $a, b$ label the different qubits. We introduce two sets of four two-qubit operators on $H = 2^{\otimes 2} \otimes 2^2$, labeled by the subscript $s = 0, 1$

$$X_s^{(0)} := \frac{1}{2} (X_a X_b^{(1)} - Y_a Y_b^{(1)}), \quad X_s^{(2)} := \frac{1}{2} (X_a^{(1)} X_b^{(1)} + Y_a^{(1)} Y_b^{(1)}),$$

$$Y_s^{(2)} := \frac{1}{2} (Y_a^{(1)} X_b^{(1)} + X_a^{(1)} Y_b^{(1)}), \quad Y_s^{(1)} := \frac{1}{2} (Y_a^{(1)} X_a^{(1)} - X_a^{(1)} Y_b^{(1)}),$$

$$Z_s^{(2)} := \frac{1}{2} (Z_a^{(1)} f_{(1)}^{(1)} + f_{(1)}^{(1)} Z_b^{(1)}), \quad Z_s^{(1)} := \frac{1}{2} (Z_a^{(1)} f_{(1)}^{(1)} - f_{(1)}^{(1)} Z_b^{(1)}),$$

$$I_s^{(2)} := \frac{1}{2} (f_{(1)}^{(1)} f_{(1)}^{(1)} + Z_b^{(1)} f_{(1)}^{(1)}), \quad I_s^{(1)} := \frac{1}{2} (f_{(1)}^{(1)} f_{(1)}^{(1)} - Z_b^{(1)} f_{(1)}^{(1)}).$$

(17)

Here, the superscript label indicates that we are dealing with two-qubit operators. Later on, $X_s^{(2)}$ will sometimes be notated...
as $X_{\text{act}}^{(2)}$, and similarly for $Y_{\text{act}}^{(2)}$, $Z_{\text{act}}^{(2)}$, and $I_{\text{act}}^{(2)}$. This more extensive labeling will prove convenient for the multiqubit generalization. Note that $(X_{\text{act}}^{(2)})^2=(Y_{\text{act}}^{(2)})^2=(Z_{\text{act}}^{(2)})^2=(I_{\text{act}}^{(2)})^2$ for $x=0,1$, and that all eight operators mutually anticommute. Furthermore, if the orientations of the two triples are the same, these two sets form representations of the generalized Pauli group, i.e., they have the same commutation relations as the Pauli matrices on $C^2$, i.e., $[X_{\text{act}}^{(2)}, Y_{\text{act}}^{(2)}]=2iZ_{\text{act}}^{(2)}$, etc. and

\[
(X_{\text{act}}^{(2)})^2 + (Y_{\text{act}}^{(2)})^2 + (Z_{\text{act}}^{(2)})^2 = (I_{\text{act}}^{(2)})^2, \quad x \in \{0,1\},
\]

with equality only for pure states.

Assume for the moment that the two-qubit state is pure and separable. We may thus write $\rho = |\Psi\rangle\langle\Psi|$, where $|\Psi\rangle = |\psi\rangle\langle\phi|$, to obtain

\[
\langle X_{0,Y}^{(2)} \rangle^2 + \langle Y_{0,Y}^{(2)} \rangle^2 = \langle X_{\text{act}}^{(2)} \rangle^2 + \langle Y_{\text{act}}^{(2)} \rangle^2
\]

\[
= \frac{1}{4} \langle (X_{a,b}^{(1)})^2 + (Y_{a,b}^{(1)})^2 \rangle (\langle (X_{a,b}^{(1)})^2 \rangle + \langle (Y_{a,b}^{(1)})^2 \rangle)
\]

\[
= \frac{1}{4} \langle (I_{a,b}^{(1)})^2 - (Z_{a,b}^{(1)})^2 \rangle (\langle (I_{a,b}^{(1)})^2 \rangle - \langle (Z_{a,b}^{(1)})^2 \rangle)
\]

\[
= \langle (I_{0,Y}^{(2)})^2 - (Z_{0,Y}^{(2)})^2 \rangle = \langle (I_{x})^2 \rangle - \langle (Z_{x})^2 \rangle.
\]

(19)

This result for pure separable states can be extended to any mixed separable state $\rho \in D^2_{2\text{-sep}}$ by noting that the density operator of any such state is a convex combination of the density operators for pure product states, i.e., $\rho = \sum p_j |\psi_j\rangle\langle\psi_j|$, with $|\psi_j\rangle = |\psi_j\rangle\langle\phi_j|$, $p_j \geq 0$, and $\sum p_j = 1$. We may thus write for such states:

\[
\max_{x \in \{0,1\}} \langle X_{x}^{(2)} \rangle^2 + \langle Y_{x}^{(2)} \rangle^2
\]

\[
\leq \min_{x \in \{0,1\}} \langle (I_{x})^2 \rangle - \langle (Z_{x})^2 \rangle, \quad \forall \rho \in D^2_{2\text{-sep}}, \quad x,y \in \{0,1\}.
\]

(20)

Here, $\langle \cdot \rangle$ denotes an expectation value in the state $|\Psi\rangle$. The first inequality follows because $\sqrt{(X_{x}^{(2)})^2 + (Y_{x}^{(2)})^2}$ are convex functions of $\rho$ for all $x$ and $y$ because $(X_{x}^{(2)})^2 - (Z_{x}^{(2)})^2$ are concave in $\rho$ for all $y$. As shown in [30] the right-hand side of this inequality is bounded by $1/2$, which follows by considering the equalities of Eq. (19). However, for entangled states, e.g., for the Bell states $|\phi^\pm\rangle = |(00) \pm (11)\rangle/\sqrt{2}$ and $|\psi^\pm\rangle = |(01) \pm (10)\rangle/\sqrt{2}$ the left-hand side can attain the value of $1$, hence inequality (20) provides a nontrivial bound for separable states, and thus a criterion for testing entanglement.

In other words, for all separable 2-qubit states one has

\[
\max_{x \in \{0,1\}} \langle X_{x}^{(2)} \rangle^2 + \langle Y_{x}^{(2)} \rangle^2
\]

\[
\leq \min_{x \in \{0,1\}} \langle (I_{x})^2 \rangle - \langle (Z_{x})^2 \rangle, \quad \forall \rho \in D^2_{2\text{-sep}}.
\]

(21)

In fact, the validity of the inequalities (21) for all orthogonal triples $\{X_a, Y_a, Z_a\}$ and $\{X_b, Y_b, Z_b\}$ provides a necessary and sufficient condition for separability for two-qubit states, pure or mixed. (See [30] for a proof.)

Note that, depending on whether the orientation of the triples of local orthogonal observables is the same or not, the inequalities on the left-hand side of Eq. (21) (leaving out the upperbound $1/4$) may be simplified. If we choose the orientations for both parties to be the same, then the interesting separability inequalities in Eq. (21) are $\langle (X_{a}^{(2)})^2 + (Y_{a}^{(2)})^2 \rangle \leq \langle (I_{a}^{(2)})^2 - (Z_{a}^{(2)})^2 \rangle$, whereas the other inequalities in Eq. (21) become trivially true [cf. Eq. (18)]. Choosing the orientations to be different reverses this verdict.

To conclude this section we give an explicit form of the separability inequalities (21) by choosing the Pauli matrices $\{\sigma_x, \sigma_y, \sigma_z\}$ for both triples $\{X_a, Y_a, Z_a\}$ and $\{X_b, Y_b, Z_b\}$. This choice enables us to write the inequalities (21) in terms of the density matrix elements on the standard $z$-basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$, labeled here as $|1\rangle, |2\rangle, |3\rangle, |4\rangle$. This choice of observables yields $(X_{a}^{(2)})^2 = 2 \text{Re} \rho_{1,4}$,

\[
\langle X_{a}^{(2)} \rangle = 2 \text{Im} \rho_{1,4}, \quad \langle Y_{a}^{(2)} \rangle = \rho_{1,4} + \rho_{4,4}, \quad \langle Z_{a}^{(2)} \rangle = \rho_{1,1} + \rho_{3,3}, \quad \langle X_{b}^{(2)} \rangle = 2 \text{Re} \rho_{2,3}, \quad \langle Y_{b}^{(2)} \rangle = -2 \text{Im} \rho_{2,3}, \quad \langle Z_{b}^{(2)} \rangle = \rho_{2,2} + \rho_{3,3}, \quad \langle Z_{b}^{(2)} \rangle = \rho_{2,2} - \rho_{3,3}.
\]

So in this choice, we can write Eq. (21) as

\[
\max \{|\rho_{1,4}|^2, |\rho_{2,3}|^2 \} \leq \min \{|\rho_{1,1}\rho_{4,4}, \rho_{2,2}\rho_{3,3} \} \leq \frac{1}{16}, \quad \rho \in D^2_{2\text{-sep}}.
\]

(22)

In the form (22), it is easy to compare the result to the separability conditions reviewed in Sec. II B. Assume for simplicity that $|\rho_{1,4}|$ is the largest of all the antidiagonal elements $|\rho_{j,k}|$. Then, for $\rho \in D^2_{2\text{-sep}}$, and using $(M_{1,2}^2 + (M_{3,4}^2)/2 \geq 8(X_{1,4}^2 + (Y_{1,4}^2))/{\text{Mermin-type separability inequality}}$ (7) becomes $|\rho_{1,4}|^2 \leq 1/16$, which is equivalent to the Laskowski-Žukowski condition $|\rho_{1,4}| \leq 1/4$; the fidelity/Dür-Cirac conditions read: $2|\rho_{1,4}| \leq \rho_{2,2} + \rho_{3,3}$; and the condition (22): $|\rho_{1,4}|^2 \leq \rho_{2,2}\rho_{3,3}$. Using the trivial inequality $\langle p_{1,4} \rangle - (\rho_{1,1} + \rho_{4,4}) \leq 2\langle p_{2,2}\rho_{3,3} \rangle \leq \rho_{2,2} + \rho_{3,3}$, we can then write the following chain of inequalities:

\[
4|\rho_{1,4}| - (\rho_{1,1} + \rho_{4,4}) \leq 2|\rho_{1,4}| \leq 2\sqrt{\rho_{2,2}\rho_{3,3}} \leq \rho_{2,2} + \rho_{3,3}.
\]

(23)

where we used the symbols $\leq$ and $\leq$ to denote inequalities that hold for all states, and for the separability condition (22), respectively.

The Laskowski-Žukowski condition is then recovered by comparing the first and fourth expressions in this chain, the fidelity/Dür-Cirac conditions by comparing the second and fourth expression, and a new condition—not previously mentioned—can be obtained by comparing the first and third term, whereas condition (22), i.e., the comparison between
the second and third expression in Eq. (23), is the strongest inequality in this chain, and thus implies and strengthens all of these other conditions.

B. Three-qubit case

We now derive separability conditions that distinguish the ten classes in the three-qubit classification of Sec. II A by generalizing the method of Sec. III A. To begin with, define four sets of three-qubit observables from the two-qubit operators (17).

\[ X_0^{(3)} := \frac{1}{2} (X^{(1)}X^{(2)}_0 - Y^{(1)}Y^{(2)}_0), \quad Y_0^{(3)} := \frac{1}{2} (Y^{(1)}X^{(2)}_0 + X^{(1)}Y^{(2)}_0), \]

\[ Z_0^{(3)} := \frac{1}{2} (Z^{(1)}I^{(2)}_0 + I^{(1)}Z^{(2)}_0), \quad I_0^{(3)} := \frac{1}{2} (I^{(1)}I^{(2)}_0 - Z^{(1)}Z^{(2)}_0), \]

\[ X_2^{(3)} := \frac{1}{2} (X^{(1)}X^{(2)}_1 - Y^{(1)}Y^{(2)}_1), \quad X_3^{(3)} := \frac{1}{2} (X^{(1)}X^{(2)}_2 + Y^{(1)}Y^{(2)}_2), \]

\[ Y_2^{(3)} := \frac{1}{2} (Y^{(1)}X^{(2)}_1 + X^{(1)}Y^{(2)}_1), \quad Y_3^{(3)} := \frac{1}{2} (Y^{(1)}X^{(2)}_2 - X^{(1)}Y^{(2)}_2), \]

\[ Z_2^{(3)} := \frac{1}{2} (Z^{(1)}I^{(2)}_1 + I^{(1)}Z^{(2)}_1), \quad Z_3^{(3)} := \frac{1}{2} (Z^{(1)}I^{(2)}_2 - I^{(1)}Z^{(2)}_2), \]

\[ I_2^{(3)} := \frac{1}{2} (I^{(1)}I^{(2)}_1 + Z^{(1)}Z^{(2)}_1), \quad I_3^{(3)} := \frac{1}{2} (I^{(1)}I^{(2)}_2 - Z^{(1)}Z^{(2)}_2), \]

(24)

where \( X^{(1)}X^{(2)}_0 = X^{(1)}_a \otimes X^{(2)}_{bc} \), etc., \( a, b, c \) label the three qubits. In analogy to the two-qubit case, we note that all these operators anticommute and that if the orientations of the triples for each qubit are the same, the operators in Eq. (24) yield representations of the generalized Pauli group: \([X_x^{(3)}, Y_x^{(3)}] = 2iZ_x^{(3)}\) for \( x = 0, 1, 2, 3 \). For convenience, we will indeed assume these orientations to be the same, unless noted otherwise. Choosing orientations differently would yield similar separability conditions, in the same vein as in the previous section. Under this choice we have, for all \( k \),

\[ \langle X_k^{(3)} \rangle^2 + \langle Y_k^{(3)} \rangle^2 + \langle Z_k^{(3)} \rangle^2 \leq \langle a^{(3)} \rangle^2, \quad \forall \rho \in D^{k}_{N} \]  

(25)

with equality only for pure states.

We now derive conditions for the different levels and classes of the partial separability classification. Most of the proofs are by straightforward generalization of the method of the previous section and these will be omitted.

Suppose first that the three-qubit state is pure and separable under split \( a-(bc) \). From the definitions (24) we obtain

\[ \langle X_0^{(3)} \rangle^2 + \langle Y_0^{(3)} \rangle^2 = \frac{1}{4} ((X_0^{(1)})^2 + (Y_0^{(1)})^2)((X_0^{(2)})^2 + (Y_0^{(2)})^2) = \langle X_0^{(3)} \rangle^2 + \langle Y_0^{(3)} \rangle^2 \]

\[ = \langle X_0^{(3)} \rangle^2 + \langle Y_0^{(3)} \rangle^2 \]

\[ = (I_0^{(1)})^2 - (Z_0^{(1)})^2 \]

\[ = \frac{1}{4} ((I_0^{(1)})^2 - (Z_0^{(1)})^2)((I_0^{(2)})^2 - (Z_0^{(2)})^2) \]

\[ = (I_0^{(3)})^2 - (Z_0^{(3)})^2, \]  

(26)

Similarly, for pure states that are separable under split \( b-(ac) \), we obtain analogous equalities by interchanging the labels \( x = 1 \) and \( x = 3 \) (denoted as \( 1 \leftrightarrow 3 \)); and for split \( c-(ab) \) by \( 1 \leftrightarrow 2 \).

Of course, these equalities hold for pure states only, but by the convex analysis of Sec. III A we obtain from Eqs. (26) and (27) inequalities for all mixed states that are biseparable under the split \( a-(bc) \):

\[ \max_{x \in [0,1]} \langle X_x^{(3)} \rangle^2 + \langle Y_x^{(3)} \rangle^2 \leq \min_{x \in [0,1]} \langle Z_x^{(3)} \rangle^2 \leq \frac{1}{4} \]

\[ \forall \rho \in D_3^{a-(bc)}. \]  

(28)

For states that are biseparable under split \( b-(ac) \) the analogous inequalities with \( 1 \leftrightarrow 3 \) hold, i.e.,

\[ \max_{x \in [1,2]} \langle X_x^{(3)} \rangle^2 + \langle Y_x^{(3)} \rangle^2 \leq \min_{x \in [1,2]} \langle Z_x^{(3)} \rangle^2 \leq \frac{1}{4} \]

\[ \forall \rho \in D_3^{b-(ac)}, \]  

(29)

and for the split \( c-(ab) \) we need to replace \( 1 \leftrightarrow 2 \):
\[
\max_{x \in [0,2]} (X^{3}_x)^2 + (Y^{3}_x)^2 \leq \min_{x \in [0,2]} (X^{3}_x)^2 - (Z^{3}_x)^2 \leq \frac{1}{4}, \\
\forall \rho \in D^3_{3(ab)}. \quad (30)
\]

A general biseparable state \( \rho \in D^3_{3-sep} \) is a convex mixture of states that are separable under some bipartite split, i.e., \( \rho = p_1 \rho_{a-b(c)} + p_2 \rho_{b-a(c)} + p_3 \rho_{c-a(b)} \) with \( \sum_{j=1}^{3} p_j = 1 \). Since \( \sqrt{(X^{3}_0)^2 + (Y^{3}_0)^2} \) is convex in \( \rho \) we get from Eqs. (28)–(30) for such a state:

\[
\frac{\sqrt{(X^{3}_0)^2 + (Y^{3}_0)^2}}{\sqrt{(X^{3}_0)^2 + (Y^{3}_0)^2}} \leq p_1 \frac{\sqrt{(X^{3}_{1})^2 - (Z^{3}_{1})^2}}{\sqrt{(X^{3}_{1})^2 - (Z^{3}_{1})^2}} + p_2 \frac{\sqrt{(X^{3}_{2})^2 - (Z^{3}_{2})^2}}{\sqrt{(X^{3}_{2})^2 - (Z^{3}_{2})^2}} + p_3 \frac{\sqrt{(X^{3}_{3})^2 - (Z^{3}_{3})^2}}{\sqrt{(X^{3}_{3})^2 - (Z^{3}_{3})^2}} + p_4 \sqrt{(X^{3}_{4})^2 - (Z^{3}_{4})^2}, \quad (31)
\]

Here \( \langle \cdot \rangle_{\rho_{a-b(c)}} \) means taking the expectation value in the state \( \rho_{a-b(c)} \), etc. Analogous bounds hold for the expressions \( \sqrt{(X^{3}_x)^2 + (Y^{3}_x)^2} \) for \( x = 1, 2, 3 \).

From the numerical upper bounds in the conditions (28)–(30) it is easy to obtain a first biseparability condition:

\[
\langle X^{3}_x \rangle^2 + \langle Y^{3}_x \rangle^2 \leq 1/4, \quad \forall \rho \in D^3_{3-sep}, \quad x \in \{0, 1, 2, 3\}. \quad (32)
\]

This is equivalent to the Laskowski–Żukowski condition (3) for \( k = 2 \), as will be shown below. However, a stronger condition can be obtained by noting that \( \sqrt{(X^{3}_x)^2 + (Y^{3}_x)^2} \) is concave in \( \rho \) so that

\[
p_1 \frac{\sqrt{(X^{3}_{1})^2 - (Z^{3}_{1})^2}}{\sqrt{(X^{3}_{1})^2 - (Z^{3}_{1})^2}} + p_2 \frac{\sqrt{(X^{3}_{2})^2 - (Z^{3}_{2})^2}}{\sqrt{(X^{3}_{2})^2 - (Z^{3}_{2})^2}} + p_3 \frac{\sqrt{(X^{3}_{3})^2 - (Z^{3}_{3})^2}}{\sqrt{(X^{3}_{3})^2 - (Z^{3}_{3})^2}} \leq \sqrt{(X^{3}_{1})^2 + (Y^{3}_1)^2}.
\]

After taking a sum over \( y \neq x \) in Eq. (33), the left-hand side of Eq. (33) is larger than the right-hand side of Eq. (31). This yields a stronger condition for biseparability of three-qubit states

\[
\langle X^{3}_x \rangle^2 + \langle Y^{3}_x \rangle^2 \leq \sum_{y \neq x} \sqrt{(X^{3}_y)^2 + (Y^{3}_y)^2} - \sqrt{(Z^{3}_y)^2}, \quad \forall \rho \in D^3_{3-sep}, \quad x, y \in \{0, 1, 2, 3\}. \quad (34)
\]

That Eq. (34) is indeed a stronger than Eq. (32) will be shown below using the density matrix representation of this condition. If one would alter the orientation of the orthogonal triple of observables for a certain qubit, then the right-hand side of Eq. (34) changes by adding either 1, 2, or 3 (modulo 3) to \( x \) in the sum on the right-hand side, depending on for which qubit the orientation was changed.

Next, consider the case of a 3-separable state, \( \rho \in D^3_{3-sep} \). One might then use the fact that this split is contained in all three bipartite splits \( a-b(c), b-a(c) \), and \( c-a(b) \) to conclude that the inequalities (28)–(30) must hold simultaneously. Thus 3-separable states must obey

\[
\max_{x} \langle X^{3}_x \rangle^2 + \langle Y^{3}_x \rangle^2 \leq \min_{x} \langle X^{3}_x \rangle^2 - \langle Z^{3}_x \rangle^2 \leq \frac{1}{4}, \quad \forall \rho \in D^3_{3-sep}. \quad (38)
\]

We have thus obtained different conditions for each of the ten classes in the full separability classification of three qubits, summarized in Table I.

Violations of these partial separability conditions give sufficient conditions for particular types of entanglement. For example, if inequality (38) is violated, then the state must be in one of the biseparable classes 2.1–2.8 or in class 1, which implies that the state is at least 2-partite entangled; if Eq. (34) violated it is in class 1 and thus fully inseparable (fully entangled), and so on.

In order to gain further familiarity with the above separability inequalities, we choose the ordinary Pauli matrices \( \{\sigma_x, \sigma_y, \sigma_z\} \) for the locally orthogonal observables \( \{X^{(1)}_x, Y^{(1)}_y, Z^{(1)}_z\} \), and formulate them in terms of density matrix elements in the standard \( z \) basis. Inequalities (28)–(30) now read successively:
Finally, condition (35) for general 3-separable states becomes

\[
\max\{|p_{1,8}|^2, |p_{2,7}|^2, |p_{3,6}|^2, |p_{4,5}|^2\} \leq \min\{|p_{1,8}|p_{2,7}, p_{2,2}, p_{3,6}, p_{4,5}\} \leq \frac{1}{64}, \quad \forall \rho \in D^3_{3-sep}. \tag{44}
\]

Note that the separability inequalities (39)–(44) all give bounds on antidiagonal elements in terms of diagonal elements.

We will now show that these bounds improve upon the separability conditions discussed in Sec. II B. We focus on the antidiagonal element \(p_{1,8}\) (i.e., we suppose that this is the largest antidiagonal matrix element) since this is easiest for comparison. However, the same argument holds for any other antidiagonal matrix element.

The Dür-Cirac conditions in terms of \(|p_{1,8}|\) read as follows. For partial separability under the split \(a-(bc): 2|p_{1,8}| \leq p_{4,4} + p_{5,5}\), under the split \(b-(ac): 2|p_{1,8}| \leq p_{3,3} + p_{6,6}\), and lastly under the split \(c-(ab): 2|p_{1,8}| \leq p_{2,2} + p_{7,7}\). Next, the Laskowski–Zukowski condition (3) gives for \(\rho \in D^2_{3-sep}\) that \(|p_{1,8}| \leq 1/4\) and for \(\rho \in D^3_{3-sep}\) that \(|p_{1,8}| \leq 1/8\). The fidelity condition (9) gives that if \(\rho \in D^3_{3-sep}\) then \(2|p_{1,8}| \leq p_{2,2} + \cdots + p_{7,7}\).

In order to show that all these conditions are implied by our separability conditions, we employ some inequalities which hold for all states \(\rho: |p_{1,8}|^2 \leq p_{1,1} + p_{8,8} [\text{this follows from Eq. (25)], and } (\sqrt{p_{4,4} - p_{5,5}})^2 \geq 0 \implies 2\sqrt{p_{4,4}p_{5,5}} \leq p_{4,4} + p_{5,5}, and similarly \(2\sqrt{p_{3,3}p_{6,6}} \leq p_{3,3} + p_{6,6}\) and \(2\sqrt{p_{2,2}p_{7,7}} \leq p_{2,2} + p_{7,7}\). Using these trivial inequalities one easily sees that the conditions (39)–(41) imply the Dür-Cirac conditions for separability under the three bipartite splits. It is also easy to see that the condition for 3-separability (44) strengthens the Laskowski–Zukowski condition (3) for \(k=3\). However, it is not so easy to see that Eq. (43) strengthens both the fidelity and Laskowski–Zukowski condition for \(k=2\). We will nevertheless show that this is indeed the case.

Let us use the symbols \(\approx\) and \(\leq\) to denote inequalities that hold for all states or for separable states, respectively. Combining the above trivial inequalities with condition (43) yields the following sequence of inequalities:

\[
\frac{4|p_{1,8}| - (p_{1,1} + p_{8,8})}{2} \leq 2\sqrt{p_{4,4}p_{5,5}} + 2\sqrt{p_{3,3}p_{6,6}} \quad \text{and } 2\sqrt{p_{2,2}p_{7,7}} \leq p_{2,2} + \cdots + p_{7,7}.
\]

The inequality between the second and third expression is Eq. (43). It implies the other inequalities that follow from
Eq. (45). Comparing the first and fourth expression of Eq. (45) one obtains the Laskowski-Żukowski condition (3), while a comparison of the second and fourth yields the fidelity criterion (9). Comparing the first and third term gives a condition which was not previously mentioned. All these are implied by condition (43).

To end this section we show that the separability inequalities for \( x=0 \) give Mermin-type separability inequalities [28]. Consider the Mermin operator for three qubits:

\[
M^{(3)} := X_a^1 X_b^1 Y_c^1 + Y_a^1 X_b^1 X_c^1 + X_a^1 Y_b^1 X_c^1 - Y_a^1 Y_b^1 Y_c^1,
\]

and define \( M'^{(3)} \) in the same way, but with all \( X \) and \( Y \) interchanged. We can now use the identity \( 16(X_0^{(3)})^2 + (Y_0^{(3)})^2 = (M^{(3)})^2 + (M'^{(3)})^2 \) to obtain from the separability conditions (32) and (38) the following quadratic inequality for \( k \)-separability:

\[
16((X_0^{(3)})^2 + (Y_0^{(3)})^2) = (M^{(3)})^2 + (M'^{(3)})^2 \leq 64 \left( \frac{1}{4} \right)^k,
\]

\( \forall \rho \in D^{k \text{-sep}} \). (47)

Of course, a similar bound holds when \( (X_0^{(2)})^2 + (Y_0^{(2)})^2 \) in the left-hand side is replaced by \( (X_0^{(3)})^2 + (Y_0^{(3)})^2 \) for \( x = 1, 2, 3 \). This reproduces, for \( N=3 \), the result (7) of Ref. [1]. From the density matrix representation, we see that these Mermin-type separability conditions are in fact equivalent to the Laskowski-Żukowski condition (3). Note that these conditions do not distinguish the different classes within level \( k=2 \), as was the case in Eqs. (39)–(41).

C. N-qubit case

In this section we generalize the analysis of the previous section to \( N \) qubits to obtain conditions for \( k \)-separability and \( \alpha_k \)-separability. The proofs are analogous to the previous cases, and will be omitted. Explicit conditions for \( k \)-separability are presented for all levels \( k=1, \ldots, N \). Further, we give a recursive procedure to derive \( \alpha_k \)-separability conditions for each \( k \)-partite split \( \alpha_k \) at all level \( k \). From these, one can easily construct the conditions that distinguish all the classes in \( N \)-partite separability classification by enumerating all possible logical combinations of separability or inseparability under each of these splits at a given level. We will, however, not attempt to write down these latter conditions explicitly since the number of classes grows exponentially with the number of qubits. We start by considering bipartite splits, and biseparable states (level \( k=2 \)), and then move upwards to obtain separability conditions for splits on higher levels.

We define \( 2^{(N-1)} \) sets of four observables \( \{X^{(N)}, Y^{(N)}, Z^{(N)}, I^{(N)}\} \), with \( x \in \{0, 1, \ldots, 2^{(N-1)}-1\} \) recursively from the \((N-1)\)-qubit observables:

\[
X_y^{(N)} := \frac{1}{2} (X^{(1)} \otimes X_y^{(N-1)} - Y^{(1)} \otimes Y_y^{(N-1)}), \quad X_{y+1}^{(N)} := \frac{1}{2} (X^{(1)} \otimes X_{y+1}^{(N-1)} + Y^{(1)} \otimes Y_y^{(N-1)}),
\]

\[
Y_y^{(N)} := \frac{1}{2} Y^{(1)} \otimes X_y^{(N-1)} + X^{(1)} \otimes Y_y^{(N-1)}), \quad Y_{y+1}^{(N)} := \frac{1}{2} (Y^{(1)} \otimes X_{y+1}^{(N-1)} - X^{(1)} \otimes Y_y^{(N-1)}),
\]

\[
Z_y^{(N)} := \frac{1}{2} (Z^{(1)} \otimes I_y^{(N-1)} + I^{(1)} \otimes Z_y^{(N-1)}), \quad Z_{y+1}^{(N)} := \frac{1}{2} (Z^{(1)} \otimes I_{y+1}^{(N-1)} - I^{(1)} \otimes Z_y^{(N-1)}),
\]

\[
l_y^{(N)} := \frac{1}{2} (I^{(1)} \otimes Z_y^{(N-1)} + Z^{(1)} \otimes I_y^{(N-1)}), \quad l_{y+1}^{(N)} := \frac{1}{2} (I^{(1)} \otimes Z_{y+1}^{(N-1)} - Z^{(1)} \otimes I_y^{(N-1)}),
\]

with \( y \) even, i.e., \( y \in \{0, 2, 4, \ldots\} \). Analogous relations between these observables hold as those between the observables (17) and (24). In particular, if the orientations of each triple of local orthogonal observables is the same, these sets form representations of the generalized Pauli group, and every \( N \)-qubit state obeys \( (X_y^{(N)})^2 + (Y_y^{(N)})^2 \leq (l_y^{(N)})^2 + (Z_y^{(N)})^2 \), with equality only for pure states.

1. Biseparability

Consider a state that is separable under some bipartite split \( \alpha_2 \) of the \( N \) qubits. For each such split we get \( 2^{(N-1)} \) separability inequalities in terms of the sets \( \{X_y^{(N)}, Y_y^{(N)}, Z_y^{(N)}, I_y^{(N)}\} \) labeled by \( x \in \{0, 1, \ldots, 2^{(N-1)}-1\} \). These separability inequalities provide necessary conditions for the \( N \)-qubit state to be separable under the split under consideration. In order to find these inequalities, we first determine the \( N \)-qubit analogs of the three-qubit pure state equalities (26) and (27) corresponding to this bipartite split. We have not found a generic expression that lists them all for each possible split and all \( x \). However, for the split where the first qubit is separated from the \((N-1)\) other qubits, i.e., \( \alpha_2=\alpha-(bc \cdots n) \) a generic form can be given:
TABLE II. Solution sets for the seven different bipartite splits of four qubits.

| Split $\alpha_k$ | $a-(bcd)$ | $b-(acd)$ | $c-(abd)$ | $d-(abc)$ | $(ab)-(cd)$ | $(ac)-(bd)$ | $(ad)-(bc)$ |
|------------------|---------|---------|---------|---------|-----------|-----------|-----------|
| $\bar{z}^2_1$   | {0.1,} | {0.3,} | {0.6,} | {0.4,} | {0.2,} | {0.7,} | {0.5,} |
| $\bar{z}^2_2$   | {2.3,} | {1.2,} | {1.7,} | {1.5,} | {1.3,} | {1.6,} | {1.4,} |
| $\bar{z}^2_3$   | {4.5,} | {5.6,} | {2.4,} | {2.6,} | {4.6,} | {2.5,} | {2.7,} |
| $\bar{z}^2_4$   | {6.7,} | {4.7,} | {3.5,} | {3.7,} | {5.7,} | {3.4,} | {3.6,} |

$\left(\langle X_{x}^{(N)} \rangle^2 + \langle Y_{x}^{(N)} \rangle^2\right)^{1/2} = \frac{1}{4} \left(\langle X_{a}^{(1)} \rangle^2 + \langle Y_{a}^{(1)} \rangle^2\right) \left(\langle X_{x}^{(N-1)} \rangle^2 + \langle Y_{x}^{(N-1)} \rangle^2\right)$

$= \langle X_{x+1}^{(N)} \rangle^2 + \langle Y_{x+1}^{(N)} \rangle^2 - \langle Z_{x}^{(N)} \rangle^2$

$= \frac{1}{4} \left(\langle f_{x}^{(N)} \rangle^2 - \langle Z_{x}^{(N)} \rangle^2\right) \left(\langle f_{x}^{(N)} \rangle^2 - \langle Z_{x}^{(N)} \rangle^2\right)$

$= \langle f_{x}^{(N)} \rangle^2 - \langle Z_{x}^{(N)} \rangle^2$, \hspace{1cm} (49)

where, without loss of generality, $x$ is chosen to be even, i.e., $x \in \{0, 2, 4, \ldots\}$. For other bipartite splits the sets of observables labeled by $x$ are permuted, in a way depending on the particular split.

For example, for $N=4$ where $x \in \{0, 1, \ldots, 7\}$ the equalities (49) give the result for the split $a-(bcd)$. The corresponding equalities for other bipartite splits are obtained by the following permutations of $x$: for split $b-(acd)$: $1 \leftrightarrow 3$ and $5 \leftrightarrow 7$; for split $c-(abd)$: $1 \leftrightarrow 6$ and $3 \leftrightarrow 4$; and for split $d-(abc)$: $1 \leftrightarrow 4$ and $3 \leftrightarrow 6$. For the split $(ab)-(cd)$: $1 \leftrightarrow 2$ and $5 \leftrightarrow 6$; for $(ac)-(bd)$: $1 \leftrightarrow 7$ and $3 \leftrightarrow 5$; and lastly, for $(ad)-(bc)$: $1 \leftrightarrow 5$ and $3 \leftrightarrow 7$.

For mixed states that are separable under a given bipartite split the equalities (49) (and their analogs obtained via suitable permutations) become inequalities. We again state them for the split $a-(bc\cdots n)$:

$$\max \left\{ \frac{1}{2} \left(\langle X_{x}^{(N)} \rangle^2 + \langle Y_{x}^{(N)} \rangle^2\right) \right\} \leq \min \left\{ \frac{1}{4} \left(\langle f_{x}^{(N)} \rangle^2 - \langle Z_{x}^{(N)} \rangle^2\right) \right\} \leq \frac{1}{4}, \ \forall \rho \in D^{a}_{N}, \ \text{with} \ x \in \{0, 2, 4, \ldots\}. \hspace{1cm} (50)$$

The proof of Eq. (50) is a straightforward generalization of the convex analysis in Sec. III A. Again, for the other bipartite splits, the labels $x$ are permuted in a way depending on the particular split.

For a general biseparable state $\rho \in D^{\text{sep}}_{N}$, we thus obtain the following biseparability conditions:

$$\langle X_{x}^{(N)} \rangle^2 + \langle Y_{x}^{(N)} \rangle^2 \leq 1/4, \ \forall \ x, \ \forall \rho \in D^{\text{sep}}_{N}, \hspace{1cm} (51)$$

which is equivalent to the Laskowski–Żukowski condition for $k=2$ (as will be shown below); and just as in the three-qubit case, we also obtain a stronger condition

$$\sqrt{\langle X_{x}^{(N)} \rangle^2 + \langle Y_{x}^{(N)} \rangle^2} \leq \sum_{y \neq x} \sqrt{\langle f_{y}^{(N)} \rangle^2 - \langle Z_{y}^{(N)} \rangle^2}, \ \forall \rho \in D^{\text{sep}}_{N}, \ \text{with} \ x, y = 0, 1, \ldots, 2^{(N-1)} - 1. \hspace{1cm} (52)$$

Violation of this inequality is a sufficient condition for full inseparability, i.e., for full $N$-partite entanglement.

The inequalities (52) are stronger than the fidelity criterion (9) and the Laskowski–Żukowski criterion (3) for $k=2$, and inequalities (50) are stronger than the Dür-Cirac condition (14) for separability under bipartite splits. This will be shown below in Sec. III C 3.

2. Partial separability criteria for levels $2<k<N$.

For levels $k>2$ we sketch a procedure to find $\alpha_{k+1}$-separability inequalities recursively from inequalities at the preceding level. Suppose that at level $k$ the inequalities are given for separability under each $k$-partite split $\alpha_{k}$ of the $N$ qubits, and that these $\alpha_{k}$-separability inequalities take the form

$$\max_{x \in z_{x}^{k}} \langle X_{x}^{(N)} \rangle^2 + \langle Y_{x}^{(N)} \rangle^2 \leq \min_{x \in z_{x}^{k}} \left(\langle f_{x}^{(k)} \rangle^2 - \langle Z_{x}^{(k)} \rangle^2\right) \leq \frac{1}{4^{(k-1)}}, \ \forall \rho \in D^{\alpha_{k}}_{N}, \ i \in \{1, 2, \ldots, 2^{(N-k)}\}, \hspace{1cm} (53)$$

where $z_{x}^{k}$ denote “solution sets” for the specific $k$-partite split $\alpha_{k}$. For example, in the case of three qubits, the solution sets for the bipartite split $a-(bc)$ are $z_{x}^{a-(bc)} = \{0, 1\}$ and $z_{x}^{a-(bc)} = \{2, 3\}$, as can be seen from Eq. (28). The solution sets for other bipartite splits can be read off Eqs. (29) and (30) so as to give $z_{x}^{b-(ac)} = \{0, 3\}$, $z_{x}^{a-(bc)} = \{1, 2\}$, and $z_{x}^{a-(bc)} = \{0, 2\}, z_{x}^{a-(bc)} = \{1, 3\}$; and for future purposes we list them for the case of four qubits in Table II above. These were obtained by determining Eq. (50) for $N=4$ and for all bipartite splits $\alpha_{k}$.

Now move one level higher and consider a given $(k+1)$-partite split $\alpha_{k+1}$. This split is contained in a total number of $\binom{k+1}{2} = k(k+1)/2$ $k$-partite splits $\alpha_{k}$. Call the collection of these $k$-partite splits $S_{\alpha_{k+1}}$. We then obtain preliminary separability
inequalities for the split $\alpha_k$ from the conjunction of all separability inequalities for the splits $\alpha_k$ in the set $S_{\alpha_{k+1}}$. To be specific, this yields
\[
\max_{x \in z_{\alpha_{k+1}}^{(k)}} \max_{\alpha_k \in S_{\alpha_{k+1}}} (X_x^{(N)})^2 + (Y_x^{(N)})^2 \leq \min_{x \in z_{\alpha_{k+1}}^{(k)}} (I_x^{(N)})^2 - (Z_x^{(N)})^2 \leq \frac{1}{4^{k-1}}, \quad \forall \rho \in D_N^{a_{k+1}}.
\] (54)

This may be written more compactly as
\[
\max_{x \in z_{\alpha_{k+1}}^{(k)}} (X_x^{(N)})^2 + (Y_x^{(N)})^2 \leq \min_{x \in z_{\alpha_{k+1}}^{(k)}} (I_x^{(N)})^2 - (Z_x^{(N)})^2 \leq \frac{1}{4^{k-1}}, \quad \forall \rho \in D_N^{a_{k+1}}, \quad i \in \{1, 2, \ldots, 2^{(N-k-1)}\}.
\] (55)

(In fact, this can be regarded as an implicit definition of the solution set $z_{\alpha_{k+1}}^{(N)}$.) More importantly, by an argument similar to that leading from Eq. (35) to Eq. (38) one finds a stronger numerical bound in the utmost right-hand side of these inequalities, namely $4^{-k}$ instead of $4^{-(k-1)}$. Thus the final result is
\[
\max_{x \in z_{\alpha_{k+1}}^{(k)}} (X_x^{(N)})^2 + (Y_x^{(N)})^2 \leq \min_{x \in z_{\alpha_{k+1}}^{(k)}} (I_x^{(N)})^2 - (Z_x^{(N)})^2 \leq \frac{1}{4^{k}}, \quad \forall \rho \in D_N^{a_{k+1}}, \quad i \in \{1, 2, \ldots, 2^{(N-k-1)}\}.
\] (56)

This shows that the $\alpha_k$-separability inequalities indeed take the same form as Eq. (53) at all levels.

As an example of this recursive procedure, take $N=4$, set $k=3$, and choose the split $a-b-(cd)$. This split is contained in three 2-partite splits $a-(bcd)$, $b-(acd)$, and $(ab)-(cd)$. Using Eq. (54) and the first, second, and fifth column of Table II one obtains the following two solutions sets for the split $a-b-(cd)$: $z_1^{a-b} = \{0, 1, 2, 3\}$ and $z_2^{a-b} = \{4, 5, 6, 7\}$. This leads to the separability inequalities
\[
\max_{x \in \{0, 1, 2, 3\}} (X_x^{(4)})^2 + (Y_x^{(4)})^2 \leq \min_{x \in \{0, 1, 2, 3\}} (I_x^{(4)})^2 - (Z_x^{(4)})^2 \leq \frac{1}{16}, \quad \forall \rho \in D_4^{a-b}.
\] (57)

For other 3-partite splits the inequalities can be obtained in a similar way as to give Table III above.

As a special case, we mention the result for full separability, i.e., for $k=N$. There is only one $N$-partite split, namely where all qubits end up in a different set. Further, there is only one solution set $z^{(N)}$ and it contains all $x \in \{0, 1, \ldots, 2^{(N-1)}-1\}$.

States $\rho$ that are separable under this split thus obey
\[
\max_x (X_x^{(N)})^2 + (Y_x^{(N)})^2 \leq \min_x (I_x^{(N)})^2 - (Z_x^{(N)})^2 \leq \frac{1}{4^{(N-1)}}, \quad \forall \rho \in D_N^{sep}.
\] (58)

Violation of this inequality is a sufficient condition for some entanglement to be present in the $N$-qubit state. The condition (58) strengthens the Laskowski-Zukowski condition (3) for $k=N$ (to be shown below).

For an $N$-qubit $k$- separable state $\rho \in D_N^{k-sep}$, i.e., a state that is a convex mixture of states that are separable under some $k$-partite split, we obtain from Eq. (56) the following $k$-separability conditions:
\[
(X_x^{(k)})^2 + (Y_x^{(k)})^2 \leq \frac{1}{4^{(k-1)}}, \quad \forall x, \quad \forall \rho \in D_N^{k-sep}.
\] (59)

which is equivalent to the Laskowski-Zukowski condition (3) for all $N$ and $k$ (this will be shown below using the density matrix formulation of these conditions). However, in analogy to Eq. (34) we also obtain the stronger condition:
\[
\forall (X_x^{(N)})^2 + (Y_x^{(N)})^2 \leq \min_{y \in \{0, 1, \ldots, 2^{N-1}\}} \sum_{y \in \{0, 1, \ldots, 2^{N-1}\}} (I_x^{(N)})^2 - (Z_x^{(N)})^2, \quad \forall \rho \in D_N^{k-sep},
\] (60)
where, for given $N, k$, and $x$, $T_{l \rightarrow j}^{N,k}$ denotes a tuple of values of $y \neq x$, each one being picked from each of the solutions sets $z_i^{N,k}$ that contain $x$, where $\alpha_l$ ranges over all the $k$-partite splits of the $N$ qubits. In general, there will be many ways of picking such values, and we use $l$ as an index to label such tuples.

For example, in the case $N=3$, there is a total of six solution sets (two for each of the three bipartite splits): $\{0, 1\}, \{2, 3\}, \{0, 2\}, \{1, 3\}, \{0, 3\}, \{1, 2\}$. If we set $x=0$ and pick a member different from 0 from each of those sets that contain 0, we find $T_{l \rightarrow j}^{3,1}=\{1,2,3\}$. This is in fact the only such choice and thus $l=1$. Thus in this example condition (60) reproduces the result (34).

As a more complicated example, take $N=4$, $k=3$, and choose again $x=0$. In this case there are six 3-partite splits each of which has two solution sets, as given in Table III. The solution sets that contain 0 are all on the top row of this table. There are now many ways of constructing a tuple by picking elements that differ from 0 from each of these sets, for example, $T_{l \rightarrow j}^{4,3}=(1,2,1,3,3,1)$, etc. In this case one has to take a minimum in Eq. (60) over all these $l=1, \ldots, 3^6$ tuples.

For $k=2$, condition (60) reduces to Eq. (52) and for $k=N$ to Eq. (58). For these values of $k$, the condition is stronger than Eq. (59) (see the next section). For $k \neq N$, this is still an open question.

To conclude this section, let us recapitulate. We have found separability conditions in terms of local orthogonal observables for each of the $N$ parties that are necessary for $k$-separability and for separability under splits $\alpha_l$ at each level on the hierarchical separability classification. Violations of these separability conditions give sufficient criteria for $k$-separable entanglement and $m$-partite entanglement with $[N/k] \leq m \leq N-k+1$. The separability conditions are stronger than the Dür-Cirac condition for separability under specific splits, and stronger than the fidelity condition and the Laskowski-Zukowski condition for biseparability. The latter condition is also strengthened for $k=N$. These implications are shown in the next section.

3. The conditions in terms of matrix elements

Choosing the Pauli matrices $\{\sigma_1^{(i)}, \sigma_2^{(i)}, \sigma_3^{(i)}\}$ as local orthogonal observables, with the same orientation at each qubit, allows one to formulate the separability conditions in terms of the density matrix elements $\rho_{ij}$ on the standard $z$ basis [31]. For these choices we obtain:

$$X_0^{(N)} = \left| 0 \right\rangle \left\langle 0^N \right| + \left| 0^N \right\rangle \left\langle 0 \right|, \quad \left\langle X_0^{(N)} \right| = 2 \operatorname{Re} \rho_{1,d},$$

$$Y_0^{(N)} = -i \left| 0 \right\rangle \left\langle 0^N \right| + i \left| 0^N \right\rangle \left\langle 0 \right|, \quad \left\langle Y_0^{(N)} \right| = -2 \operatorname{Im} \rho_{1,d},$$

$$I_0^{(N)} = 0 \left| 0 \right\rangle \left\langle 0^N \right| + \left| 0^N \right\rangle \left\langle 0 \right|, \quad \left\langle I_0^{(N)} \right| = \rho_{1,1} + \rho_{d,d},$$

$$Z_0^{(N)} = 0 \left| 0 \right\rangle \left\langle 0^N \right| - \left| 0^N \right\rangle \left\langle 0 \right|, \quad \left\langle Z_0^{(N)} \right| = \rho_{1,1} - \rho_{d,d}. \quad (61)$$

The analogous inequalities for separability under other bipartite splits are obtained by suitable permutations on the labels. Indeed, for split $b-(acd)$ labels 8 and 5, 9 and 12, 2 and 3, and 5 and 14 are permuted, which we denote as $(8,9,2,15) \leftrightarrow (5,12,3,14)$; for split $c-(abcd)$: $(8,9,2,15) \leftrightarrow (3,14,5,12)$; for split $d-(abc)$: $(8,9,3,14) \leftrightarrow (2,15,5,12)$; for the split $(ab)-(cd)$: $(8,9,3,14) \leftrightarrow (4,13,7,10)$; for $(ac)-(bd)$: $(8,9,5,12) \leftrightarrow (6,11,7,10)$; and lastly, for the split $(ad)-(bc)$: $(8,9,5,12) \leftrightarrow (7,10,6,11).$ For a general biseparable state we obtain

$$\left| \rho_{1,16} \right| \leq \sqrt{\rho_{2,2,15,15} + \rho_{3,3,14,14} + \cdots + \rho_{8,8,9,9}}, \quad \forall \rho \in D_{3}^{b-(cd)}, \quad (63)$$

and analogous for the other antiorthogonal elements.

Next, consider one level higher, i.e., $k=3$. There are six different 3-partite splits for a system consisting of four qubits. For separability under each such split a different set of inequalities can be obtained from Eq. (54). To be more precise, such a set consists of the conjunction of all the separability inequalities for the bipartite splits at level $k=2$ this particular 3-partite split is contained in. For $N=4$ each 3-partite split is contained in three bipartite splits. For example, for separability under split $a-b-(cd)$ we obtain

$$\max \left\{ |\rho_{1,16}|^2, |\rho_{8,9}|^2, |\rho_{14,14}|^2, |\rho_{12,12}|^2 \right\} \leq \min \left\{ \rho_{1,16}, \rho_{8,8}, \rho_{9,9}, \rho_{14,14}, \rho_{12,12} \right\} \leq 1/64,$$

$$\max \left\{ |\rho_{2,2,15,15}|^2, |\rho_{3,3,14,14}|^2, |\rho_{6,6,11,11}|^2, |\rho_{7,7,10,10}|^2 \right\} \leq \min \left\{ \rho_{2,2,15,15}, \rho_{3,3,14,14}, \rho_{6,6,11,11}, \rho_{7,7,10,10} \right\} \leq 1/64,' \quad \forall \rho \in D_{3}^{a-b-(cd)} \quad (64).$$

This is the density matrix formulation of Eq. (57).

A general 3-separable state $\rho \in D_{3}^{3-sep}$ is a convex mixture of states that each are separable under some such 3-partite split. The separability condition follows from Eq. (60):
\[ |\rho_{1,16}| \leq \min_{\lambda} \left( \frac{1}{2} \sum_{j \in T^0_{1,6}} (\rho_{j,j} \rho_{17-j,17-j}) \right), \quad \forall \rho \in D^3_{4,sep}, \]  

(65)

where \( T^0_{1,6} \) is the tuple of indices \( j \) in \( \{1,16\} \) that label the antidiagonal density matrix elements \( \rho_{1,17-j} \) corresponding to the density matrix formulation of the set of operators \( \{X^{(y)}\} + \{Y^{(y)}\} \) with \( y \) determined by \( T^0_{1,6} \). Here we have used that the antidiagonal element \( \rho_{1,16} \) corresponds to \( \{X^{(y)}\} + \{Y^{(y)}\} \). For \( N=4, k=3 \) there are six possible splits, so for each \( l, j \) is picked from a total of six sets. For the case under consideration the sets are \( \{1, 4, 5, 8\}, \{2, 3, 4\}, \{1, 3, 5, 7\}, \{1, 2, 5, 6\}, \{1, 2, 7, 8\}, \) and \( \{1, 3, 6, 8\} \). For each \( j \) one chooses a tuple of values of \( j \) where one value is picked from each of these six sets, except for the value 1 which is excluded. Analogous inequalities are obtained for the other antidiagonal matrix elements.

Finally for full separability \((k=4)\) we get

\[ \max\{|\rho_{1,16}^2|,|\rho_{2,15}^2|,\ldots,|\rho_{8,9}^2|\} \leq \min\{|\rho_{1,1}|\rho_{16,16}|,|\rho_{2,2}|\rho_{15,15}|,\ldots,|\rho_{8,8}|\rho_{9,9}|\} \leq 1/256, \quad \forall \rho \in D^4_{4,sep}. \]  

(66)

For general \( N \), it is easy to see that Eq. (51) yields the Laskowski-Zukowski condition (3). It is instructive to look at the extremes of biseparability and full separability, since for them explicit forms can be given. For \( k=2 \) condition (52) reads

\[ |\rho_{l}| \leq \sum_{n \neq l,d} \sqrt{\rho_{n,n'}} \rho_{d,d'}/2, \quad \forall \rho \in D^{2-sep}_N, \quad \text{where } l = d + 1 - n, \quad n, l \in \{1, \ldots, d\}. \]

(67)

For \( k=N \), we can reformulate condition (58) as

\[ \max\{|\rho_{l,d}|^2,|\rho_{l,d-1}|^2,\ldots\} \leq \min\{|\rho_{1,1}|\rho_{16,16}|,|\rho_{2,2}|\rho_{15,15}|,\ldots,|\rho_{8,8}|\rho_{9,9}|\} \leq 1/4^N, \quad \forall \rho \in D^{N-sep}_N. \]

(68)

It is easily seen that the condition (68) is stronger than the Laskowski-Zukowski condition (3). Again, these inequalities give bounds on antidiagonal matrix elements in terms of diagonal ones on the \( z \) basis. These density matrix representations depend on the choice of the Pauli matrices as the local observables. However, every other triple of locally orthogonal observables with the same orientation can be obtained from the Pauli matrices by suitable local basis transformations, and therefore this matrix representation does not lose generality. Choosing different orientations of the triples one obtains the corresponding inequalities by suitable permutations of antidiagonal matrix elements.

We will now show that Eq. (67) is indeed stronger than the fidelity condition (9) and the Laskowski-Zukowski condition (3) for \( k=2 \) by following the same analysis as in the three-qubit case. We again assume, for convenience, that the antidiagonal element \( \rho_{1,d} \) is the largest of all antidiagonal elements. Using some inequalities that hold for all states together with the condition (67) for biseparability we get the following sequence of inequalities for \( \rho_{1,d} \):

\[ 4 |\rho_{1,d}|^2 - (\rho_{1,1} + \rho_{d,d})^2 \leq 2 |\rho_{1,d}|^2 - 2 \rho_{2,2} \rho_{1,d-1,d-1}^2 + \cdots + 2 \rho_{d,d-2} \rho_{d,2} + \rho_{d-1,d-1}. \]

(69)

The inequality in the middle is Eq. (67). It implies all other inequalities in the sequence (69). The inequality between the first and fourth term yields the Laskowski-Zukowski condition for \( k=2 \), and between the second and fourth gives the fidelity criterion in the formulation (11). One also sees that the fidelity criterion is stronger than the Laskowski-Zukowski condition for \( k=2 \).

We finally discuss two examples showing that the biseparability condition (67) is stronger in detecting full entanglement than other methods. First, consider the family of \( N \)-qubit states

\[ \rho_N = \lambda_0^N |\psi_0^N\rangle \langle \psi_0^N| + \lambda_0^N |\psi_0^N\rangle \langle \psi_0^N| + \sum_{j=1}^{2^{N-1}} \lambda_j^N (|\psi_j^N\rangle \langle \psi_j^N| + |\psi_j^N\rangle \langle \psi_j^N|), \]

(70)

The states (70) violate Eq. (67) for all \( |\lambda_0^N - \lambda_0^N| \neq 0 \) and are thus detected as fully entangled by that condition. In that case they are also inseparable under any split. The fidelity criterion (11), however, detects these states as fully entangled only for \( |\lambda_0^N - \lambda_0^N| = \sum \lambda_j^N \). Violation of Eq. (67) thus allows for detecting more states of the form \( \rho_N \) as fully entangled than violation of the fidelity criterion. Further, the Dür-Cirac criteria detects these states as inseparable under any split for \( |\lambda_0^N - \lambda_0^N| \geq 2 \lambda_j^N \), which includes less states than a violation of Eq. (67). This generalizes the observation of Ref. [32] from two qubits to the \( N \)-qubit case.

Second, consider the \( N \)-qubit GHZ-like states \( |\theta\rangle = \cos \theta |\theta\rangle^N + \sin \theta |\bar{\theta}\rangle^N \). We can easily read off from the density matrix \( |\theta\rangle \langle \theta| \) that the far off-antidiagonal matrix elements \( \rho_{1,d} = \rho_{d,1} \) is equal to \( \cos \theta \sin \theta \) and that the diagonal matrix elements\( \rho_{2,2}, \ldots, \rho_{d-1,d-1} \) are all equal to zero. Using Eq. (67) we see that these states are fully \( N \)-partite entangled for \( \rho_{1,d} = \cos \theta \sin \theta \neq 0 \), i.e., for all \( \theta \neq 0, \pi/2 \) (mod \( \pi \)). Thus all fully entangled states of this form are detected by condition (67), including those not detectable by any standard multiparticle Bell inequality [33].

4. Relationship to Mermin-type inequalities for partial separability and LHV models

We will now show that the separability inequalities of the previous section imply already known Mermin-type inequalities [28] for partial separability. Using the identity
\[2^{(N+1)}(x_0^{(N)})^2 + (y_0^{(N)})^2 = (M^{(N)})^2 + (M^\dagger)^2 \text{ for the Mermin operators}\]

\begin{equation}
(M^{(N)})^2 + (M^\dagger)^2 \leq 2^{(N+3)}\left(\frac{1}{4}\right)^k, \quad \forall \rho \in D_N^{k-sep},
\end{equation}

which reproduces the result (7) found by [1]. Since Eq. (51) is equivalent to Eq. (3) we see that the Mermin-type separability condition is in fact one of the Laskowski-Żukowski conditions written in terms of local observables X and Y.

As a special case we consider a split of the form \(\{1,\ldots,\kappa\},\{\kappa+1,\ldots,n\}\). Any state that is separable under this split is \((\kappa+1)\text{-separable}\) so we get the condition \(\langle M^{(N)}\rangle^2 + \langle M^\dagger\rangle^2 \leq 2^{(N-2\kappa+1)}\), and hence \(\langle M^{(N)}\rangle \leq 2^{(N-2\kappa+1)/2}\). This strengthens the result of Gisin and Bechmann-Pasquinucci [9] by a factor \(2^{\kappa/2}\) for this specific Mermin operators (6).

As another special case of the inequalities (71), consider \(k=N\). In this case, the inequalities express a condition for full separability of \(\rho\). These inequalities are maximally violated by fully entangled states by an exponentially increasing factor of \(2^{N-1}\), since the maximal value of \(\langle M^{(N)}\rangle\) for any quantum state \(\rho\) is \(2^{(N+1)/2}\) [34]. Furthermore, LHV models violate them also by an exponentially increasing factor of \(2^{(N-1)/2}\), since for all \(N\), LHV models allow a maximal value for \(\langle M^{(N)}\rangle\) of 2 [9,13], which is a factor \(2^{(N-1)/2}\) smaller than the quantum maximum using entangled states. This bound for LHV models is sharp since the maximum is attained by fully entangled states by an exponentially increasing factor of 2\(^{N-1}\).

That the maximum violation of multipartite Bell inequalities allowed by quantum mechanics grows exponentially with \(N\) with respect to the value obtainable by LHV models has been known for quite some years [28,34]. However, it is equally remarkable that the maximum value obtainable by entangled quantum states exponentially increases in comparison to the maximum value obtainable by LHV models, cf. Fig. 2. We thus see exponential divergence between separable quantum states and LHV theories: as \(N\) grows, the latter are able to give correlations that need more and more entanglement in order to be reproducible in quantum mechanics.

But why does quantum mechanics have correlations larger than those obtainable by a LHV model? Here we give an argument showing that it is not the degree of entanglement but the degree of inseparability that is responsible. The degree of entanglement of a state may be quantified by the value \(m\) that indicates the \(m\)-partite entanglement of the state, and the degree of inseparability by the value of \(k\) that indicates the \(k\)-separability of the state. Now suppose we have 100 qubits. For partial separability of \(k \geq 51\) no state of these 100 qubits can violate the Mermin inequality (8) above the LHV bound, although the state could be up to 50-partite entangled \((m \leq 50)\). However, for \(k=2\), a state is possible that is also 50-partite entangled, but which violates the Mermin inequality by an exponentially large factor of \(2^{97/2}\). For \(k < N\), a \(k\)-separable state is always entangled in some way, so we see that it is the degree of partial separability, not the amount of entanglement in a multiqubit state that determines the possibility of a violation of the Mermin inequality. Of course, some entanglement must be present, but the inseparability aspect of the state determines the possibility of a violation. This is also reflected in the fact that for a given \(N\) it is the value of \(k\), and not that of \(m\), which determines the sharp upper bounds of the Mermin inequalities.

IV. EXPERIMENTAL STRENGTH OF THE CONDITIONS FOR \(k\)-SEPARABLE ENTANGLEMENT DETECTION

Violations of the above conditions for partial separability provide sufficient criteria for detecting \(k\)-separable entanglement (and \(m\)-partite entanglement with \(N/m \leq N-k+1\)). It has already been shown that these criteria are stronger than the Laskowski-Żukowski criterion for \(k\)-inseparability for \(k=2, N\) (i.e., detecting some and full entanglement), the fidelity criterion for full inseparability (i.e., full entanglement), and the Dür-Cirac criterion for inseparability under splits. In this section we will elaborate further on the experimental usefulness and strength of these entanglement criteria when focusing on specific \(N\)-qubit states. The strength of an entanglement criterion to detect a given entangled state may be assessed by determining how well it copes with two desiderata [11]: the noise robustness of the criterion for this given state should be high, and the number of local measurements settings needed for its implementation should be small.

In this section we will first take a closer look at the issue of noise robustness and at the number of required settings for implementation of the separability criteria, both in the general state-independent case and in the case of detecting target states. We then show the strength of the criteria for a variety of specific \(N\)-qubit states.
A. Noise robustness and the number of measurement settings

White noise robustness of an entanglement criterion for a given entangled state is the maximal fraction $p_0$ of white noise which may be admixed to this state so that the state can no longer be detected as entangled by the criterion. Thus for a given entangled state $\rho$, the noise robustness of a criterion is the threshold value $p_0$ for which the state $\rho = p\rho_0 + (1-p)\rho$, with $p \geq p_0$, can no longer be detected by that criterion.

So, for the criterion for detecting full entanglement (67), the white noise robustness is found by solving the threshold equation for $p_0$:

$$|(1-p_0)\rho_{ij}| = \sum_{j\neq l} \sqrt{\left|\frac{P_0}{2N} + (1-p_0)P_{jj}\right|}\left|\frac{P_0}{2N} + (1-p_0)P_{jj}\right|.$$  \hspace{1cm} (72)

The state is fully entangled for $p < p_0$.

For the criterion (68), for detecting some entanglement, one finds a similar threshold equation:

$$\max_i \left|\left| (1-p_0)\rho_{ij}\right|^2 \right| = \min_j \left( \left|\frac{P_0}{2N} + (1-p_0)P_{jj}\right|\left|\frac{P_0}{2N} + (1-p_0)P_{jj}\right|\right).$$  \hspace{1cm} (73)

This equation is quadratic and easily solved. Again, the state is entangled for $p < p_0$.

A local measurement setting [35–37] is an observable such as $M = \sigma_1 \otimes \sigma_1 \cdots \otimes \sigma_N$, where $\sigma_i$ denote single qubit observables for each of the $N$ qubits. Measuring such a setting (determining all coincidence probabilities of the $2^N$ outcomes) also enables one to determine the probabilities for observables like $1 \otimes \sigma_1 \cdots \otimes \sigma_N$, etc. [15]. Now consider the observables $X^{(N)}_i$ and $Y^{(N)}_i$ that appear in the separability criteria of Eqs. (49)–(60). As it is easily seen from their definitions in Eq. (48), one can measure such an observable using $2^N$ local settings. However, these same $2^N$ settings then suffice to measure the observables $X^{(N)}_i$ and $Y^{(N)}_i$ for all other $x$ since these are linear combinations of the same settings. Thus $2^N$ measurement settings are sufficient to determine $X^{(N)}_i$ and $Y^{(N)}_i$ for all $x$. It remains to determine the number of settings needed for the terms $I^{(N)}_i$ and $Z^{(N)}_i$. For all $x$ these terms contain only two single-qubit observables: $Z^{(1)}_i$ and $I^{(1)}_i$. They can thus be measured by a single setting, i.e., $(Z^{(1)}_i) \otimes \cdots \otimes (Z^{(1)}_i)$.

Thus in total $2^N+1$ settings are needed in order to test the separability conditions. This number grows exponentially with the number of qubits. However, this is the price we pay for being so general, i.e., for having criteria that work for all states. If we apply the criteria to detecting forms of inseparability and entanglement of specific entangled $N$-qubit states, this number can be greatly reduced. Knowledge of the target state enables one to select a single separability inequality for an optimal value of $x$ in Eqs. (49)–(54) and (56)–(60). Violation of this single inequality is then sufficient for detecting the entanglement in this state, and, as we will now show, the required number of settings then grows only linear in $N$, with $N+1$ being the optimum for many states of interest.

For simplicity, assume that the local observables featuring in the criteria are the Pauli spin observables with the same orientation for each qubit. We can then readily use the density matrix representations of the separability criteria given at the end of each section in Sec. III. Choosing the local observables differently amounts to performing suitable bases changes to the density matrix representations and would not affect the argument.

The matrix representations of the conditions show that only some anti-diagonal matrix elements and the values of some diagonal matrix elements have to be determined in order to test whether these inequalities are violated. Indeed, observe that for all $x$, $(I^{(N)}_i)^2 - (Z^{(N)}_i)^2 = 4P_{ij}P_{jj}$ with $j = d + 1 - j$ for some $j \in \{1, 2, \ldots, d\}$ and $(X^{(N)}_i)^2 - (Y^{(N)}_i)^2 = 4P_{jj}P_{ij}$ denotes some anti-diagonal matrix element. It suffices to consider $x = 0$ since conditions for other values of $x$ are obtained by some local unitary basis changes that will be explicitly given later on. We now want to rewrite the density matrix representation for this single separability inequality with $x=0$ in terms of less than $2^N+1$ settings.

Determining the diagonal matrix elements requires only a single setting, namely $\sigma_2^{\otimes N}$. Next, we should determine the modulus of the far-off anti-diagonal element $P_{1,d}$ ($d = 2^N$) by measuring $X^{(N)}_0$ and $Y^{(N)}_0$, since $\langle X^{(N)}_0 \rangle = 2 \Re P_{1,d}$ and $\langle Y^{(N)}_0 \rangle = 2 \Im P_{1,d}$ [cf. Eq. (61)]. Following the method of [15], these matrix elements can be obtained from two settings $\mathcal{M}_1$ and $\tilde{\mathcal{M}}_1$, given by

$$\mathcal{M}_1 = \left[ \cos \left( \frac{1}{N} \pi \right) \sigma_1 + \sin \left( \frac{1}{N} \pi \right) \sigma_2 \right] \otimes \cdots \otimes \left[ \cos \left( \frac{1}{N} \pi \right) \sigma_1 + \sin \left( \frac{1}{N} \pi \right) \sigma_2 \right] \otimes \cdots \otimes \left[ \cos \left( \frac{1}{N} \pi \right) \sigma_1 + \sin \left( \frac{1}{N} \pi \right) \sigma_2 \right],$$  \hspace{1cm} (74)

$$\tilde{\mathcal{M}}_1 = \left[ \cos \left( \frac{1}{N} \pi + \frac{\pi}{2} \right) \sigma_1 + \sin \left( \frac{1}{N} \pi + \frac{\pi}{2} \right) \sigma_2 \right] \otimes \cdots \otimes \left[ \cos \left( \frac{1}{N} \pi + \frac{\pi}{2} \right) \sigma_1 + \sin \left( \frac{1}{N} \pi + \frac{\pi}{2} \right) \sigma_2 \right] \otimes \cdots \otimes \left[ \cos \left( \frac{1}{N} \pi + \frac{\pi}{2} \right) \sigma_1 + \sin \left( \frac{1}{N} \pi + \frac{\pi}{2} \right) \sigma_2 \right],$$  \hspace{1cm} (75)

These operators obey

$$\sum_{l=1}^N (-1)^l \mathcal{M}_1 = N X^{(N)}_0,$$  \hspace{1cm} (76)

$$\sum_{l=1}^N (-1)^l \tilde{\mathcal{M}}_1 = N Y^{(N)}_0.$$  \hspace{1cm} (77)

The proof of Eq. (76) is given in [15] and Eq. (77) can be proven in the same way.

These relations show that the imaginary and the real part of an anti-diagonal element can be determined by the $N$ settings $\mathcal{M}_1$ and $\tilde{\mathcal{M}}_1$, respectively. This implies that the biseparability condition (67) needs only $2N+1$ measurement settings. However, if each anti-diagonal term is real valued (which is often the case for states of interest) it can be determined by the $N$ settings $\mathcal{M}_1$ so that in total $N+1$ settings suffice.
Implementation of the criteria for other $x$ involves determining the modulus of some other antidiagonal matrix element instead of the far-off antidiagonal element $\rho_{ij}$. The settings that allow for this determination can be obtained from a local unitary rotation on the settings $M_l$ and $\tilde{M}_l$ needed to measure $|\rho_{ij}|$. This can be done as follows.

Suppose we want to determine the modulus of the matrix element $\rho_{ij}$. The unitary rotation to be applied is given by $U_l=j_{ij} \sigma_0 \otimes \sigma_1 \otimes \cdots \otimes \sigma_{N-1}$ in binary notation, with $\sigma_0=1$ and $\sigma_j=\sigma_z$. The settings that suffice are then given by $M_{l,j}=U_lM_lU_l^\dagger$ and $\tilde{M}_{l,j}=U_l\tilde{M}_lU_l^\dagger$ ($l=1,2,\ldots,N$). For example, take $N=4$ and suppose we want to determine $\rho_{3,4}$. We obtain the required settings by applying the local unitary $U_3=1 \otimes \sigma_x \otimes 1 \otimes \sigma_z$ (since the binary notation of 5 on four bits is 0101) to the two settings $M_l$ and $\tilde{M}_l$ given in Eqs. (74) and (77), respectively, that for $N=4$ allow for determining $|\rho_{ij}|$. In conclusion, using the above procedure the modulus of each antidiagonal element can be determined using $2N$ settings, and in case they are real (or imaginary) $N$ settings suffice.

Since the strongest separability inequality for the specific target state under consideration is chosen, this reduction in the number of settings does not reduce the noise robustness for detecting forms of entanglement as compared to that obtained using the entanglement criteria in terms of the usual settings $X^{(N)}_l$, etc.

In conclusion, if the state to be determined is known, the $2N$ settings of Eqs. (74) and (75) together with the single setting $\sigma_{N-1}^{(N)}$ suffice, and in case this state has solely real or imaginary antidiagonal matrix elements only $N+1$ settings are needed. The white noise robustness using these settings is just as great as using the general condition that use the observables $X^{(N)}_l$ and $Y^{(N)}_l$, and is found by solving Eqs. (72) or (73) for detecting full and some entanglement, respectively.

As a final note, we observe that in order to determine the modulus of not just one but of all antidiagonal matrix elements it is more efficient to use the observables $X^{(N)}_l$ and $Y^{(N)}_l$ than the observables of Eqs. (74) and (75). The first method needs $2N$ settings to do this and the second needs $2N/2$ settings (since there are $2N/2$ independent antidiagonal elements), i.e., the latter needs more settings than the former for all $N$.

Let us apply the above procedure to an example, taken from Ref. [15], the so-called four-qubit singlet state, which is given by

$$|\Phi_0\rangle = \frac{1}{\sqrt{3}} \left(|0011\rangle + |1100\rangle - \frac{1}{2}(|01\rangle \otimes |01\rangle + |10\rangle \otimes |10\rangle) \right).$$

(78)

For detecting it as fully entangled Eq. (72) gives a noise robustness $p_0=12/29 \approx 0.41$, and for detecting it as entangled Eq. (73) gives a noise robustness of $16/19=0.84$. The implementation needs $16+1=17$ settings.

This number of settings can be reduced by using the fact that this state has only real antidiagonal matrix elements and that we need only look at the largest antidiagonal element. As shown above, this matrix element can be measured in four settings. Thus the total number of settings required is reduced to only five. The off-diagonal matrix element to be determined is $|0011\rangle|1100\rangle$. The four settings that allow for this determination are obtained from the four settings given in Eq. (74) by applying the unitary operator $U_3=1 \otimes 1 \otimes \sigma_x \otimes \sigma_z$ to these settings.

For comparison, note that in Ref. [15] it was shown that the so-called projector-based witness for the state (78) detects full entanglement with a white noise robustness $p_0=0.267$ and uses 15 settings, whereas the optimal witness from [15] uses only three settings and has $p_0=0.317$. Here we obtain $p_0=0.41$ using five settings, implying a significant increase in white noise robustness using only two settings more.

This example gives the largest noise robustness when the conditions are measured in the standard $z$ basis. However, sometimes one obtains larger noise robustness when the state is first rotated so as to be expressed in a different basis before it is analyzed. For example, consider the four-qubit Dicke state (2,4), where $|I,N\rangle=(I^{12})^{-1/2}\sum_\pi \pi(I_1,1,\ldots,0_{n+1},0_{n+2},\ldots,0_n)$ are the symmetric Dicke states [38] with $\pi(I_1)$ the set of all distinct permutations of the $N$ qubits. In this basis the state does not violate any of the separability conditions we have discussed above. However, if each qubit is rotated around the $x$ axis by $90^\circ$ all of the separability conditions can be violated with quite high noise robustness. Indeed, it is detected as inseparable under all splits through violation of conditions (50) for $p < p_0=16/19=0.84$ and as fully entangled through violation of condition (52) for $p < p_0=4/11 \approx 0.36$ using five settings. For comparison, Chen et al. [16] used specially constructed entanglement witnesses for detection of full entanglement in these states, and they obtained as noise robustness $p_0=2/9=0.22$ using only two settings. We have not performed an optimization procedure, so it is unclear whether or not the values obtained for $p_0$ can be improved.

### B. Noise and decoherence robustness for the $N$-qubit GHZ state

In this section we determine the robustness of our separability criteria for detecting the $N$-qubit GHZ state in five kinds of noise processes (admixing white and colored noise, and three types of decoherence: depolarization, dephasing, and dissipation of single qubits). We give the noise robustness as a function of $N$ for detecting some entanglement, inseparability with respect to all splits and full entanglement. We compare the results for white noise robustness of the criteria for full entanglement to that of the fidelity criterion (10) and to that of the so-called stabilizer criteria of Refs. [17,39].

The $N$-qubit GHZ state $|\Psi_{\text{GHZ},0}\rangle=\frac{1}{\sqrt{2}}(|00\cdots0\rangle+|11\cdots1\rangle)$ can be transformed into a mixed state $\rho_{\text{GHZ}}$ by admixing noise to this state or by decoherence. Let us consider the following five such processes.

(i) Mixing in a fraction $p$ of white noise (also called “generalized Werner states” [40]) gives

$$\rho_N^{(i)}=(1-p)|\Psi_{\text{GHZ},0}\rangle\langle \Psi_{\text{GHZ},0}|+p\frac{1}{2^N}.$$  

(79)
(ii) Mixing in a fraction \( p \) of colored noise \([17]\) gives
\[
\rho_N^{(ii)} = (1 - p)\Psi_{GHZ,0}^N + \frac{p}{2} |0\cdots0\rangle\langle0\cdots0| + |1\cdots1\rangle\langle1\cdots1|.
\] (80)

(iii) A depolarization process \([18]\) with a depolarization degree \( p \) of a single qubit gives
\[
\rho_N^{(iii)} = \frac{1}{2} \left( |0\rangle\langle0| + \frac{p}{2} |1\rangle\langle1| \right)^{\otimes N} + \left( 1 - \frac{p}{2} \right) |0\rangle\langle1| + |1\rangle\langle0| \right)^{\otimes N}.
\] (81)

(iv) A dephasing process \([18]\) with a dephasing degree \( p \) of a single qubit gives
\[
\rho_N^{(iv)} = \frac{1}{2} \left( |0\rangle\langle0|^{\otimes N} + |1\rangle\langle1|^{\otimes N} + (1 - p^2) |0\rangle\langle1|^{\otimes N} |1\rangle\langle0|^{\otimes N} \right).
\] (82)

(v) A dissipation process \([18]\) with a dissipation degree \( p \) of a single qubit (where the ground state is taken to be \( |0\rangle \)) gives
\[
\rho_N^{(v)} = \frac{1}{2} \left( |0\rangle\langle0|^{\otimes N} + |p\rangle\langle0|\left( 1 - p \right) |1\rangle\langle1|^{\otimes N} \right) + (1 - p)^{\otimes N} |0\rangle\langle0|^{\otimes N} + |1\rangle\langle1|^{\otimes N}.
\] (83)

We now consider the question for what values of \( p \) these states \( \rho_N^{(i)} \) to \( \rho_N^{(v)} \) are detected as (i) containing some entanglement by the condition \((58)\), and (ii) inseparable under any split by the conditions of the form \((50)\) for all bipartite splits. In other words, we determine the noise (or decoherence) robustness of violations of all these conditions for \( \rho_N^{(i)} \) to \( \rho_N^{(v)} \).

We find the following threshold values \( p_0 \):

(i) \( p_0 = \frac{1}{1 + 2^{1-N}} \),

(ii) \( p_0 = 1 \), \( \forall N \),

(iii) \( (1 - p_0)^N = \left( 1 - \frac{p_0}{2} \right)^a \left( \frac{p_0}{2} \right)^{(N-a)} + \left( 1 - \frac{p_0}{2} \right)^{(N-a)} \left( \frac{p_0}{2} \right)^a \),

(iv) \( p_0 = 1 \), \( \forall N \),

(v) \( p_0 = 1 \), \( \forall N \). (84)

For cases (i), (ii), (iv), and (v) the threshold values \( p_0 \) for detecting some entanglement and inseparability with respect to all splits are the same because for these cases the product of the diagonal matrix elements \( p_{ij}, p_{jj} \) is the same for all \( j \neq 1,d \). Only in case (iii) is this product different for different \( j \). We then have to take the minimum and maximum value, respectively, from which it follows that \( p_0 \) is to be set to \([N/2]\) for detecting some entanglement and to 1 for detecting inseparability with respect to all splits. Here \([N/2]\) is the largest integer smaller or equal to \( N/2 \).

The result in case (i) is in accordance with the results of Refs. \([2,4]\), where it is furthermore shown that the opposite holds as well, i.e., if and only if \( p < 1/(1 + 2^{1-N}) \) then \( \rho_N^{(i)} \) is inseparable under any split and otherwise it is fully separable. Thus all states of the form \((79)\) that are inseparable under any split are detected by violations of the conditions of the form \((50)\) for all bipartite splits. The same holds for cases (ii), (iv), and (v), since all states \( \rho_N^{(i)} \), \( \rho_N^{(iv)} \), and \( \rho_N^{(v)} \) are inseparable under any split for all \( p < 1 \). In other words, as soon as a fraction of the GHZ state is present, these states are inseparable under any split. In case (i) \( p_0 \) increases monotonically from \( p_0 = 2/3 \) for \( N=2 \) to \( p_0 = 1 \) for large \( N \). For process (iii) these limiting values are not so straightforward: \( p_0 = (3 - \sqrt{3})/3 \approx 0.42 \) for \( N=2 \), and \( p_0 = (5 - \sqrt{5})/5 \approx 0.55 \) for large \( N \). In conclusion, the noise and decoherence robustness is high for all \( N \), except maybe for case (iii).

Next, consider the noise robustness for detecting full entanglement by means of the biseparability condition \((52)\). The result is the following:

(i) \( p_0 = 1/[2(1 - 2^{N})] \),

(ii) \( p_0 = 1 \), \( \forall N \),

(iii) \( p_0 \approx 0.42, 0.28, 0.22, 0.18 \), \( N = 2, 3, 4, 5 \),

(iv) \( p_0 = 1 \), \( \forall N \),

(v) \( p_0 \approx 1.048, 0.39, 0.35 \), \( N = 2, 3, 4, 5 \). (85)

For case (i) the noise robustness is equivalent to the fidelity criterion \((10)\). For large \( N \) \( p_0 \) decreases to the limit value \( p_0 = 1/2 \). Cases (ii) and (iv) have \( p_0 = 1 \), thus as soon as the states \( \rho_N^{(ii)} \) and \( \rho_N^{(iv)} \) are entangled they are fully entangled. For cases (iii) and (v) we listed the noise robustness found numerically for \( N=2 \) to 5. These values decrease for increasing \( N \).

Let us compare the results for white noise robustness [case (i)] to the results obtained from the so-called stabilizer formalism. This formalism \([41]\) is used by Tóth and Gühne to derive entanglement witnesses \([11,39]\) that are especially useful for minimizing the number of settings required to detect either full or some entanglement. Here we will only consider the criteria formulated for detecting entanglement of the \( N \)-qubit GHZ states. The stabilizer witness by Tóth and Gühne that detects some entanglement has \( p_0 = 2/3 \), independent of \( N \), and requires only three settings [cf. Eq. (13) in \([11]\)]. The strongest witness for full entanglement of Tóth and Gühne has a robustness \( p_0 = 1/(3 - 2^{2-N}) \) and requires only two settings [cf. Eq. (23) in \([11]\)].

Figure 3 shows these threshold noise ratios for detecting full entanglement for these three criteria. Note that the criterion of Tóth and Gühne \([11]\) needs only two measurement settings, whereas our criteria need \( N+1 \) settings. So although the former are less robust against white noise admixture,
they compare favorably with respect to minimizing the number of measurement settings.

Although we give a criterion for full entanglement that is generally stronger than the fidelity criterion, for the $N$-partite GHZ state this does not lead to better noise robustness. It appears that for large $N$ the noise threshold $p_0 = 1/2$ is the best one can do. However, in the limit of large $N$ the GHZ state is inseparable under all splits for all $p_0 < 1$, as was shown in (i) in Eq. (84), see also Fig. 3. Furthermore, we have seen that if the state $\rho_N^{(0)}$ (i.e., the GHZ state with a fraction $p$ of white noise) is entangled it is also inseparable under any split. Because of the high symmetry of both the GHZ state and white noise, one might conjecture that if the state $\rho_N^{(0)}$ is entangled it is also fully entangled. At present, however, it is unknown whether this is indeed true. Detecting the states $\rho_N^{(0)}$ as fully entangled appears to be a much more demanding task than detecting them as inseparable under all splits. In the first case, for large $N$, only a fraction of 50% noise is permitted, in the second case one can permit any noise fraction (less than 100%). Note that we have given explicit examples of states that are diagonal in GHZ basis [cf. Eq. (14) of Sec. II B], and that are inseparable under any split, but not fully entangled; but these are not of the form $\rho_N^{(0)}$.

Lastly, we mention that our criteria detect the various forms of entanglement and inseparability also if the state $|\Psi_{\text{GHZ},0}\rangle$ is replaced by any other maximally entangled state [i.e., any state of the GHZ basis, cf. Eq. (13)], a feature which is not possible using linear entanglement witnesses. There is no single linear witness that detects entanglement of all maximally entangled states.

C. Detecting bound entanglement for $N \geq 3$

Violation of the separability inequality (58) allows for detecting bound entangled states of Ref. [42]. These states have the form

$$
\rho_B = \frac{1}{N+1} \left( |\Psi_{\text{GHZ},0}\rangle \langle \Psi_{\text{GHZ},0}| + \frac{1}{2} \sum_{i=1}^{N} P_i + \bar{P}_i \right),
$$

with $P_i$ the projector on the state $|0\rangle_i\cdots|1\rangle_i\cdots|0\rangle_N$, and where $\bar{P}_i$ is obtained from $P_i$ by replacing all zeros by ones and vice versa. For $N \geq 4$ these states are entangled and have positive partial transposition (PPT) with respect to transposition of any qubit. This means they are bound entangled [43]. Note that they are detected as entangled by the $N$-partite Mermin inequality $|M_N| = 2$ of Sec. III C only for $N \geq 8$ [42]. However, the condition (58) detects them as entangled for $N \geq 4$. Thus all bound entangled states of this form are detected as entangled by this latter condition. The white noise robustness for this purpose is $p_0 = \frac{2^{N}/(2+2N+2^N)}{N+1} = \frac{2^{N}}{N+1} + \frac{N}{2(N+1)}$, which for $N = 4$ gives $p_0 = \frac{8}{13} = 0.615$ and goes to 1 for large $N$. Note that for $N = 4$, this state violates the condition for 4-separability, and the condition for 3-separability (60), but not the condition for 2-separability. It is thus at least 2-separable entangled. It is not detected as fully entangled by these criteria. (Of course, it could still be fully entangled since these criteria are only sufficient and not necessary for entanglement.) For general $N$ we have not investigated the $k$-separable entanglement of the states (86), although this can be readily performed using the criteria of Eq. (60).

Another interesting bound entangled state is the so-called four-qubit Smolin state [44]

$$
\rho_S = \frac{1}{4} \sum_{j=1}^{4} |\Psi_{ab}\rangle \langle \Psi_{ab}| \otimes |\Psi_{cd}\rangle \langle \Psi_{cd}|,
$$

where $\{|\Psi_i\rangle\}$ is the set of four Bell states $\{|\phi^+\rangle, |\phi^-\rangle\}$, and $a,b,c,d$ label the four qubits. This state is also detected as entangled by the criterion (58), and with white noise robustness $p_0 = 2/3$. The Smolin state violates the separability conditions (50) for biseparability under the splits $a-(bcd), b-(acd), c-(abd), d-(abc)$. However, it is separable under the splits $(ab)-(cd), (ac)-(bd), (ad)-(bc)$ (cf. [44]). This state is thus inseparable under splits that partition the system into two subsets with one and three qubits, but it is separable when each subset contains two qubits.

So far we have detected bound entanglement for $N \geq 4$. What about $N = 3$? Consider the three-qubit bound entangled state of [3]:

$$
\rho = \frac{1}{3} |\Psi_{\text{GHZ}}\rangle \langle \Psi_{\text{GHZ}}| + \frac{1}{6} (|001\rangle \langle 001| + |010\rangle \langle 010| + |101\rangle \langle 101| + |110\rangle \langle 110|).
$$

This state is detected as entangled by the criterion (35), with white noise robustness $p_0 = 4/7 \approx 0.57$. It violates the biseparability condition (28) for the split $a-(bc)$ so it is at least biseparable entangled, but does not violate the condition (34) for biseparability, i.e., it is not detected as fully entangled. In fact, it can be shown using the results of Ref. [4] that this state is separable under the splits $b-(ac)$ and $c-(ab)$.

V. DISCUSSION

We have discussed partial separability of quantum states by distinguishing $k$-separability and $\epsilon_k$-separability and used these distinctions to extend the classification proposed by
Orthogonality of the local observables is crucial in the above derivation of separability conditions. It is due to this assumption that the multiqubit operators form representations of the generalized Pauli group. It would be interesting to analyze the role of orthogonality in deriving the inequalities. For two qubits it has been shown [45] that when orthogonality is relaxed the separability conditions become less strong, and we conjecture the same holds for their multiqubit analogs. Relaxing the requirement of orthogonality has the advantage that some uncertainty in the angles may be accommodated, which is desirable since in real experiments it may be hard to measure perfectly orthogonal observables.

It is also interesting that the separability inequalities are equivalent to bounds on antidiagonal matrix elements in terms of products of diagonal ones. We thus gain a novel perspective on why they allow for entanglement detection: they probe the values of antidiagonal matrix elements, which encode entanglement information about the state; and if these elements are large enough, this entanglement is detected. Note, furthermore, that compared to the Mermin-type separability inequalities we need not do much more to obtain our stronger inequalities. We must solely determine some diagonal matrix elements, and this can be easily performed using the single extra setting $\sigma_0^{N}$. It is also noteworthy that the comparison to the Mermin-type separability inequalities shows that the strength of the correlations allowed for by separable states is exponentially decreasing when compared to the strength of the correlations allowed for by LHV models.

Our recursive definition of the multipartite correlation operators [see Eq. (48)] is by no means unique. One can generate many new inequalities by choosing the locally orthogonal observables differently, e.g., by permuting their order in each triple of local observables. It could well be that combining such inequalities with those presented here yield even stronger separability conditions, as is indeed the case for pure two-qubit states, cf. [30]. Unfortunately, we have no conclusive answers for this open question.

We end by suggesting three further lines of future research. First, it would be interesting to apply the entanglement criteria to an even larger variety of $N$-qubit states than analyzed here, including, for example, all $N$-qubit graph and Dicke states. Second, the generalization from qubits to qudits (i.e., $d$-dimensional quantum systems) would, if indeed possible, prove very useful since strong partial separability criteria for $N$ qudits have—to our knowledge—not yet been obtained. Finally, it would be beneficial to have optimization procedures for choosing the set of local orthogonal observables featuring in the entanglement criteria that gives the highest noise robustness for a given set of states. We believe we have chosen such optimal sets for the variety of states analyzed here, but since no rigorous optimization was performed, our choices could perhaps be improved.

ACKNOWLEDGMENT

We thank Géza Tóth and Otfried Gühne for fruitful discussions on the strength of multipartite entanglement criteria.

[24] For example, consider the following construction (inspired by Ref. [21]) where we use the N-qubit states $|\psi_i\rangle = |e_1\rangle|0\rangle|0\rangle\cdots|0\rangle_N$, $|\phi_2\rangle = |0\rangle|e_2\rangle|0\rangle\cdots|0\rangle_N\cdots$, $|\phi_0\rangle = |0\rangle|0\rangle|0\rangle\cdots|e_{N-1}\rangle_N$, where $|e_i\rangle$ is any entangled pure state of the two parties $i$ and $j$. Then the state $\rho = \sum_{i=1}^N |\psi_i\rangle\langle\psi_i|/N$ is inseparable under all splits, yet by construction $(N-1)$-separable.
