Abstract

Background: Free radical is a crucial factor for progression of COPD. Antioxidant enzymes, including superoxide dismutase (SOD) and catalase (CAT) have been well known to reduce morbidity of chronic disease. Vitamin D₃ has antioxidant effect in human body. Objectives: To assess the effects of D₃ supplementation on plasma SOD and CAT levels in D₃ deficient COPD patients. Method: A double blinded placebo controlled randomized clinical trial was carried out on 30 vitamin D₃ deficient male, smoker and stable COPD patients of age >40 years. All the patients were randomly allocated to ‘Study’ (n=15) or ‘Control’ (n=15) and their baseline plasma SOD and CAT were measured. Study patients received 80,000 IU (2 oral capsules) of D₃ per week for first 13 weeks. Subsequently, after checking their serum 25(OH)D or Ca²⁺, they received 40,000 IU (1 oral capsule) of D₃ either per 1 week or per 2 weeks or per 6 weeks or no further supplementation for next 13 weeks. All the ‘Control’ patients received two oral capsules of placebo weekly for consecutive 26 weeks. Additionally, all patients of both groups were also advised to have sunlight exposure (within 11 to 14 hrs) at least for 5 to 15 minutes daily. After 26 weeks of follow up, both enzymes, serum 25(OH)D or Ca²⁺ of all patients were measured by spectrophotometry. Data were analyzed by
Introduction

One of the major causes of chronic morbidity and mortality throughout the world is Chronic obstructive pulmonary Disease (COPD).[^1] It is characterized by persistent respiratory symptoms and airflow limitation due to airway and/or alveolar abnormalities usually caused by significant exposure to noxious particles or gases[^1].

This respiratory ailment is currently fourth leading cause of death in the world but it is projected to be third leading cause of death by 2020[^1]. In Bangladesh, prevalence of COPD among people greater than 40 years is 21.6% and overall prevalence in general population is 4.32%.[^2]

Lungs are continuously exposed to free radicals originated from air pollution or cigarette smoke and excess oxidants can cause destruction of the lung.[^3-4] Therefore, body antioxidants from different sources protect our body from the damaging effect of these exogenous or endogenous free radicals.[^5] Several antioxidant enzymes in our body provide the first line defense by neutralizing these free radicals. Among these antioxidant enzymes, superoxide dismutase (SOD) and catalase (CAT) are important for respiratory organs.[^5] Previous studies reported decreased SOD and CAT activity in COPD patients compared to healthy control.[^7-8]

Vitamin D₃ deficiency is a recent rising problem in general population throughout the world.[^9] In respiratory health, vitamin D₃ deficiency has been shown to increase the risk of active tuberculosis[^10] and upper respiratory tract infections.[^11] It is believed that patients with COPD are at greater risk of vitamin D₃ deficiency.[^12] In addition, research evidence indicate positive correlation between serum vitamin D₃ and erythrocyte SOD and CAT activity.[^13] Furthermore, vitamin D₃ supplementation increased both (SOD and CAT) in diabetic mice[^14], hemodialysis patient[^15], preeclamptic women[^16] as well as in vitamin D₃ deficient patients with stable asthma-COPD overlap patients.[^17]

Nevertheless, the volume of information regarding the role of vitamin D₃ supplementation (as an antioxidant) on plasma antioxidant enzymes status is very scarce for any conclusive remarks.

Therefore, this study was designed to observe the effect of vitamin D₃ supplementation on plasma SOD and CAT level in vitamin D₃ deficient stable COPD patients.

Method

Study design, setting, time:

This randomized double blinded placebo controlled trail was conducted in the Department of Physiology, Bangabandhu Sheikh Mujib...
D₃ supplementation on antioxidant enzymes in D₃ deficient COPD. Anjum et al.

Medical University (BSMMU) and National Institute of the Diseases of Chest and Hospital (NIDCH), Dhaka from March, 2019 to February, 2020. This clinical trial was registered at www.clinicaltrials.gov, ID: NCT04011930 and approved by Institutional Review Board of BSMMU.

Study population:
For this purpose, 30 (thirty) male, smoker, stable patients with COPD of age ≥40 years were enrolled by purposive sampling. Diagnosis was done by pulmonologists through clinical, physical and radiological signs of chronic airway disease, usually with spirometric evidence of chronic airflow limitation (post bronchodilator FEV₁/FVC<0.7)₁, but its absence did not absolutely exclude COPD. Duration of COPD (1 to 5 years), duration of smoking (>10 pack years)₁₈, body mass index (18.5 to 24.9 kg/m²)₁₉, serum total calcium (8.5 to 10.5 mg/dl)²₀, serum inorganic phosphate (2.3 to 4.7 mg/dl)²₀ and serum parathormone (10 to 65 pg/ml)²₀ were inclusion criteria. In addition, patients with uncontrolled diabetes mellitus (fasting blood sugar ≥7 mmol/l and/or HbA₁c ≥7%)²¹, uncontrolled systemic hypertension (systolic blood pressure ≥140 mm Hg and/or diastolic blood pressure ≥90 mm Hg, with anti-hypertensive medication)²², dyslipidemia (total cholesterol ≥240 mg/dl and/or HDL<40 mg/dl and/or LDL≥160 mg/dl and/or triglyceride≥200 mg/dl and/or with use of any lipid lowering drug)²₃, renal insufficiency (serum creatinine >1.36 mg/dl)²₄ as well as history of any pulmonary, liver, endocrine or cardiac disease, malignancy or with consumption of any drug known to affect vitamin D metabolism (phenytoin, carbamazepine, clotrimazole, rifampicin, nifedipine, spironolactone) within 1 month prior to study, were excluded.

Randomization:
The final selection of vitamin D₃ deficient ACO patients (after screening) were done by principal investigator. Then a code was provided to each of them (to hide their identity) and with the help of a computer-generated random table, all were randomly allocated into vitamin D supplemented group (n=26) or placebo treated group (n=25) (Figure 1). Both the randomization and blinding were done by a third party, not member of the research team. Neither the principal investigator nor the patients were aware about the grouping. Before the data analysis, grouping of the patient was disclosed.

Intervention:
Study patients received 80,000 IU (2 oral capsules) of vitamin D₃ per week for first 13 weeks. Detail of the dose schedule for D₃ supplementation for last 13 weeks²⁵ are shown in Table I. In this study design, all the ‘Control’ patients received two oral capsules of placebo weekly for consecutive 26 weeks. Additionally, all the patients of both groups were also advised to have sunlight exposure (within 11 am to 2 pm)²₆ only for 5 to 15 minutes daily.²₇ During the follow up after 13 weeks, if serum 25(OH)D level was found <10 ng/ml (severely deficiency)²₅ in any patient, then he was discarded (Figure 1) from the study (for ethical purpose). Ingredients of vitamin D₃ capsules were cholecalciferol (40,000 IU), microcrystalline cellulose (58.1 gm), butylatedhydroxy toluene (0.2 mg), magnesium stearate (3 mg), gelatin capsule shell (1 mg). Placebo was identical in all aspect to that of vitamin D₃ and ingredients of placebo were same as vitamin D₃ except Cholecalciferol. Vitamin D₃ and placebo capsules were prepared and supplied by Beximco Pharmaceuticals Limited, Bangladesh. After explaining the dose schedule and possible side effects of drug (vitamin D₃ or placebo) the patient consumed the first dose, given by the investigator and then followed the subsequent doses as instructed throughout the intervention period. Patients were advised to continue the standard pharmacological treatment...
of COPD (according to GOLD criteria) throughout the intervention period.

Data collection.
An informed written consent was taken from each preliminarily selected patient and their serum 25(OH)D level was estimated. Patients with 25(OH)D level between 10-30 ng/ml was finally enrolled as vitamin D₃ deficient and. Before administration of vitamin D₃ or placebo the baseline plasma level of SOD and CAT of all patients were measured and at the end of 26 weeks follow up, both the enzyme levels and vitamin D₃ level of both groups were again measured.

Serum 25(OH)D was assessed by Chemiluminescent microparticle immunoassay (CMIA) method (Abbot Laboratory, Ireland). Plasma SOD and CAT enzyme levels were assessed by colorimetric method using SOD assay kit (Elabscience, USA) and CAT assay kit (Elabscience, USA).

Statistical Analysis. The data were expressed as mean±SD and the data were analyzed by SPSS (Version 20), and for statistical analysis, Shapiro-Wilk test, independent sample ‘t’ test as well as paired sample ‘t’ test were used as applicable. In the interpretation of results, p≤0.05 was accepted as significant.

---

**Figure 1:** CONSORT (Consolidated Standards of Reporting Trials) diagram; COPD: Chronic obstructive pulmonary disease
Results
A total of 30 patients were initially randomized and 20 of them ultimately completed the study (7 patients from study group and 3 patients from control groups were dropped out) (Figure 1).

Both the groups (with vitamin D₃ and placebo) at their baseline status were comparable, as there were no significant differences of the confounding variables (age, duration of COPD, duration of smoking, BMI, socioeconomic status, fasting blood sugar, lung function Serum 25(OH)D, parathormone, total calcium, inorganic phosphate serum glycated hemoglobin, systolic and diastolic blood pressure) between them (Table II).

There was no significant difference in the baseline characteristics including antioxidant enzymes (SOD and CAT) between study and control groups (Figure 2). However, the mean plasma SOD (p≤0.01) as well as CAT (p≤0.001) significantly increased after 26 weeks of follow-up.

Table I: D₃ supplementation schedule for D₃ deficient COPD patients

At 1st visit / at day 1:
Vitamin D₃ 80,000 IU (2 capsules of 40,000 IU) / week, for consecutive 13 weeks

At 2nd visit / after 13 weeks:

| Condition | Dosage | Notes |
|-----------|--------|-------|
| Serum 25(OH)D ≥ 80 ng/ml and/or Serum Ca²⁺ ≥ 8.5-10.5 mg/dl | Stop taking drug and symptom analysis | No dose for further 13 weeks |
| 50-80 ng/ml and/or 8.5-10.5 mg/dl | 1 cap (40,000 IU) / 6 weeks |
| <80 ng/ml and/or <8.5-10.5 mg/dl | no dose for further 13 weeks |
| >150 ng/ml and/or >8.5-10.5 mg/dl | Close monitoring and ask for – feeling sick or being sick • poor appetite or loss of appetite • feeling very thirsty • passing urine often • constipation or diarrhea • abdominal pain • muscle weakness • pain • bone pain • feeling confused • feeling tired |

At 3rd visit / after 26 weeks:
Patients were referred to pulmonologist and suggested to follow the above mentioned schedule.
Table II: Baseline characteristics of COPD patient in both groups (N=30)

| Characteristics                     | Study (n=15) | Control (n=15) | p value |

D₃ supplementation on antioxidant enzymes in D₃ deficient COPD. Anjum et al.

Discussion

The present study has been undertaken to observe the effects of vitamin D₃ supplementation on plasma antioxidant enzymes in vitamin D₃ deficient stable patients with COPD.

In this study, both the plasma SOD and CAT levels in the D₃ deficient stable male patients with COPD, at their baseline status, were almost similar to those reported by others¹³,¹⁵.

In this study, plasma SOD and CAT significantly increased in D₃ deficient patients with COPD after 26 weeks of vitamin D₃ administration in comparison to their baseline status. Similar observation in SOD and CAT level were found in erythrocytes of patients with atopic dermatitis after 60 days of vitamin D₃ supplementation¹³.

Moreover these antioxidant enzymes were found to be increased in serum after 8 weeks¹⁶ as well as in plasma after 26 weeks¹⁷ of vitamin D₃ supplementation in patients with preeclampsia and asthma-COPD overlap patients, respectively.

In addition, in the current study, after 26 weeks of follow up, SOD and CAT were significantly higher in plasma of our COPD patients with vitamin D₃ supplementation in comparison to that of patients with placebo. Similar observation was found in erythrocytes of atopic dermatitis patients on 60th day²¹ in liver tissue of diabetic rats on 28th day²⁸, in serum of preeclamptic pregnant women after 8 weeks¹⁶ and in plasma of vitamin D₃ deficient asthma-COPD overlap patients on 26th week¹⁷ after different dose schedule of vitamin D₃ supplementation.

Moreover, SOD was higher in plasma of neonates with hypoxic-ischemic encephalopathy on 5th day²⁹ in cardiac tissue of obese rat on 5th week³⁰ of vitamin D₃ supplementation.

In addition, CAT was also found higher in hippocampus of vitamin D₃ supplemented rats with multiple sclerosis on 21st day of follow up³¹.

Figure 2: Antioxidant enzyme levels on pre and post intervention in both groups; Each bar symbolizes mean±SD of stable COPD patients; Study1: Patients with vitamin D₃ on day 1; Study2: Patients with vitamin D₃ after 26th week; Control1: Patients with placebo on day 1; Control2: Patients with placebo after 26th week; ***: p<0.001 in A1 vs A2; ###: p<0.001 in A2 vs B2; **: p<0.01 in A1 vs A2.
From the present study, the exact cause of increment of SOD and CAT after vitamin D$_3$ supplementation in COPD patients is uncertain. However, being a steroid through its genomic effect, vitamin D$_3$ might induce the mRNA gene expression of the antioxidant enzymes, SOD and CAT through Sirtuin1 (SIRT1) expression.\footnote{Halliwell B, Whiteman M. Measuring reactive species and oxidative damage in vivo and in cell culture; how should you do it and what do the results mean? Br J Pharmacol 2004; 142(2):231-55. doi: 10.1038/sj.bjp.0705776}

**Conclusion**
The outcome of this trial reveals that vitamin D$_3$ supplementation increases the antioxidant enzymes in D$_3$ deficient COPD patients.

**Limitation**
In this trial both of diabetes mellitus and hypertension were included which would cause oxidative stress, we intended to exclude the COPD patients with these two co-morbidities. But it could not be possible, due to patients unavailability and time constraint.

Therefore, similar study is recommended in nondiabetic as well as normotensive male COPD patients. In addition, other antioxidant enzymes should be assessed with different dose and follow up schedule of this fat soluble vitamin supplementation in D$_3$ deficient COPD patients to ascertain our findings.
