(Dated: July 14, 2009; revised November 10, 2009)

We study the effect of a right-handed coupling of quarks to the W-boson on the measurements of $|V_{ub}|$ and $|V_{cb}|$. It is shown that such a coupling can remove the discrepancies between the determinations of $|V_{ub}|$ from $B \to \pi \ell \nu$, $B^+ \to \pi^+ \nu$ and $B \to X_u \ell \nu$. Further the measurements of $|V_{cb}|$ from $B \to D^* \ell \nu$, $B \to D \ell \nu$ and inclusive $B \to X_c \ell \nu$ decays can be brought into better agreement. We demonstrate that a right-handed coupling can be generated within the MSSM by a finite gluino-squark loop. The effect involves the parameters $\delta_{2R}^{UR}$ and $\delta_{3R}^{UR}$ of the squark mass matrices, which are poorly constrained from other processes. On the other hand, all gluino-squark corrections to the regular left-handed coupling of the W-boson are found to be too small to be relevant.

I. INTRODUCTION

In the standard model (SM) with its gauge group $SU(3)_C \times SU(2)_L \times U(1)$ the tree-level W coupling has a pure $V-A$ structure meaning that all charged currents are left-handed. Right-handed charged currents were first studied in the context of left-right symmetric models which enlarge the gauge group by an additional $SU(2)_R$ symmetry between right-handed doublets. In these models new right-handed gauge bosons $W_R$, $Z_R$ appear and the physical SM-like W-boson has a dominant left-handed component with a small admixture of $W_R$. The latter will generically lead to small right-handed couplings to both quarks and leptons. The right-handed mass scale inferred from today’s knowledge on neutrino masses is so large that all right-handed gauge couplings are undetectable. Most of these couplings are further experimentally strongly constrained. A different source of right-handed couplings of quarks to the W-boson can be loop effects, which generate a dimension-six quark-quark-W vertex. In this case no right-handed lepton couplings occur, as long as the neutrinos are assumed left-handed. A generic analysis of such higher-dimensional right-handed couplings has been studied in Ref. aiming at a better understanding of $K \to \pi \mu \nu$ data. The general effect of left- and right-handed anomalous couplings of the W to charm was studied in Ref. The authors conclude that only the real part of the right-handed charm-bottom coupling can be sizable. The coupling of the W to up has been studied in.

We will investigate the effect of a right-handed W-coupling on the extraction of $|V_{ub}|$ and $|V_{cb}|$ in section II and show that current tensions between SM and data can be removed. In section III we will calculate the loop-corrected W-coupling in the generic Minimal Supersymmetric Standard Model (MSSM). We find that the right-handed W-coupling can be as large as 20% and brings the different determinations of $|V_{ub}|$ into perfect agreement.

The effect on $|V_{cb}|$ is at most around 2%, which alleviates the tension studied in Sec. II. Finally we conclude.

II. RIGHT-HANDED W COUPLINGS

An appropriate framework for our analysis is an effective Lagrangian. Following the notation of Ref., we write

$$\mathcal{L} = \mathcal{L}_{SM} + \frac{1}{\Lambda} \sum_i C^{(5)}_i Q^{(5)}_i + \frac{1}{\Lambda^2} \sum_i C^{(6)}_i Q^{(6)}_i + \mathcal{O}\left(\frac{1}{\Lambda^3}\right),$$

where $\mathcal{L}_{SM}$ is the standard model (SM) Lagrangian, while $Q^{(n)}_i$ stand for dimension-$n$ operators built out of the SM fields and are invariant under the SM gauge symmetries. Such an effective theory approach is appropriate for any SM extension in which all new particles are sufficiently heavy ($M_{new} \sim \Lambda \gg m_t$). As long as only processes with momentum scales $\mu \ll \Lambda$ are considered, all heavy degrees of freedom can be eliminated, leading to the effective theory defined in. The operators $Q^{(5)}_i$ and $Q^{(6)}_i$ have been completely classified in Ref. Since $Q^{(5)}_i$ involve no quark fields, they are not needed for our further discussion, and we skip the superscripts “(5)” at the dimension-six operators and the associated Wilson coefficients $C_i$. In this article, we need the following dimension-six operator describing anomalous right-handed W-couplings to quarks:

$$Q_{RR} = \bar{u}f \gamma^\mu P_R d_i \left(\tilde{\phi}^i iD^\mu \phi \right) + h.c.,$$

where $\phi$ denotes the Higgs doublet and $\tilde{\phi} = i\tau^2 \phi^*$. The Feynman rule for the $W-u_f-d_i$ interaction vertex,

$$-ig_2 \gamma^\mu \frac{1}{\sqrt{2}} \left(V^{L}_{fi}P_L + V^{R}_{fi}P_R \right),$$
is found by combining the usual SM interaction with the extra contributions that are obtained by setting the Higgs field in Eq. (2) to its vacuum expectation value. In Eq. (3) $V^L_{ij}$ and $V^R_{ij}$ denote elements of the effective CKM matrices, which are not necessarily unitary. $V^R_{ij}$ is related to the Wilson coefficient in Eq. (1) via $V^R_{ij} = \frac{C_{RR}}{2\sqrt{2}G_F\Lambda^2}$. $V^L_{ij}$ receives contributions from the tree-level CKM matrix and the LL analogue of $Q_{RR}$ in Eq. (4).

Right-handed couplings to light quarks have been studied in Ref. [3] and to charm (up) quarks in Ref. [4] (Ref. [5]). Ref. [9] examines such couplings in inclusive decays. In Ref. [6] it was pointed out that very strong constraints can be obtained on $V^R_{ub}$ from $b \to s\gamma$, because the usual helicity suppression factor of $m_b/M_W$ is absent in the right-handed contribution. By the same argument $V^R_{ub}$ (or $V^R_{cb}$ if one considers $b \to d\gamma$) is tightly constrained. Large effects concerning transitions between the first two generations are unlikely, because $V^R_{ub}$ and $V^R_{cb}$ are larger than other off-diagonal CKM elements. Further deviations from Minimal Flavour Violation (as defined in [10]), i.e. deviations from Yukawa-driven flavour transitions, are unlikely in the first two generations, but plausible with respect to transitions involving the third generation [11]. We therefore focus our attention on the remaining two elements $V^L_{ub}$ and $V^L_{cb}$.

### A. Determination of $V^L_{ub}$ and $V^L_{cb}$

The experimental determination of $|V_{ub}|$ and $|V_{cb}|$ from both inclusive and exclusive $B$ decays is a mature field by now [2]. E.g. the form factors needed for $B \to \pi\nu\bar{\nu}$ are known to 12% accuracy [12]. More recently, also the leptonic decay $B \to \tau\nu\bar{\nu}$ is studied in the context of $V_{ub}$. To discuss the impact of right-handed currents we denote the CKM element extracted from data with SM formula by $V_{qb}$, where $q = u$ or $q = c$. If the matrix element of a considered exclusive process is proportional to the vector current, $V_{qb}^L$ and $V_{qb}^R$ enter with the same sign and the

\[ |V^L_{qb}| \text{ as a function of } \text{Re}[V^R_{qb}/V^L_{qb}] \text{ extracted from different processes. Blue(darkest): inclusive decays. Red(gray): } B \to \tau\nu. \text{ Yellow(lightest gray): } V_{qb} \text{ determined from CKM unitarity.} \]

\[ FIG. \ 1: \ |V^L_{qb}| \text{ as a function of } \text{Re}[V^R_{qb}/V^L_{qb}] \text{ extracted from different processes. Blue(darkest): inclusive decays. Red(gray): } B \to \tau\nu. \text{ Yellow(lightest gray): } V_{qb} \text{ determined from CKM unitarity.} \]

\[ V^L_{qb} = V_{qb} - V^R_{qb} \]

For processes proportional to the axial-vector current $V^R_{qb}$ enters with the opposite sign as $V^L_{qb}$, so that

\[ V^L_{qb} = V_{qb} + V^R_{qb}. \]

In inclusive decays the interference term between the left-handed and right-handed contributions is suppressed by a factor of $m_b/m_t$, so that it is irrelevant in the case of $V_{tb}$ and somewhat suppressed in the case of $V_{cb}$. The remaining dependence on $V_{qb}$ is quadratic and therefore negligible.

Starting with $|V_{ub}|$, we note that the determinations from inclusive and exclusive semileptonic decays agree within their errors, but the agreement is not perfect [2, 13]. The analysis of $B \to \tau\nu$ is affected by the uncertainty in the decay constant $f_B$. Within errors the three determination of $|V_{ub}|$ are compatible, as one can read off from Fig. 1. The picture looks very different once the information from a global fit to the unitarity triangle (UT) is included: As pointed out first by the CKMfitter group, the measured value of $B \to \tau\nu$ suffers from a tension with the SM of 2.4–2.7σ [13]. First, the global UT fit gives a much smaller error on $|V_{ub}|$ (as a consequence of the well-measured UT angle $\beta$); the corresponding value is also shown in Fig. 1. Second, the data on $B_d-B_s$ mixing exclude very large values for $f_B$, which in turn cut out the lower part of the yellow (light gray) region in Fig. 1. Essentially we realize from Fig. 1 that we can remove this tension while simultaneously bringing the determinations of $|V_{ub}|$ from inclusive and exclusive semileptonic decays into even better agreement. For this the right-handed component must be around $|V^L_{qb}/V^L_{ub}| \approx -0.15$. Since new physics may as well affect the other quantities entering the UT, a more quantitative statement requires the consideration of a definite model.

Next we turn to $V_{cb}$. The relative uncertainties in the exclusive decays $B \to D^*\tau\nu$ and $B \to D\tau\nu$ and in the

\[ FIG. \ 2: \ |V^L_{qb}| \text{ as a function of } \text{Re}[V^R_{qb}/V^L_{qb}] \text{ extracted from different processes. Blue(darkest): inclusive decays. Red(gray): } B \to \tau\nu. \text{ Yellow(light gray): } B \to D\tau\nu. \]

"true" value of $V^L_{qb}$ in the presence of $V^R_{qb}$ is given by:

\[ V^L_{qb} = V_{qb} - V^R_{qb} \]

(4)

For processes proportional to the axial-vector current $V^R_{qb}$ enters with the opposite sign as $V^L_{qb}$, so that

\[ V^L_{qb} = V_{qb} + V^R_{qb}. \]

(5)
inclusive $B \to X_c \ell\nu$ analyses are much smaller than in the $b \to u$ decays considered above. Note that $B \to D\ell\nu$ only involves the vector current so that Eq. (4) applies. $B \to D^{\ast}\ell\nu$ receives contributions from both vector and axial vector currents, but the contribution from the vector current is suppressed in the kinematic endpoint region used for the extraction of $|V_{cb}|$. Therefore Eq. (5) applies to $B \to D^{\ast}\ell\nu$. The impact of a right-handed current on $B \to X_c \ell\nu$ has been calculated in Ref. 9. Fig. 2 shows that the agreement among the three values of $|V_{cb}|$ obtained from these decay modes is not totally satisfactory within the SM. One further realizes that we can reduce the discrepancy to less than $1\sigma$ if a right-handed coupling in the range $0.03 \leq \text{Re} \left| V_{cb}^{R}/V_{cb}^{L} \right| \leq 0.06$ is present.

## III. MSSM Renormalization of the Quark-Quark-W Vertex

In Ref. 11 the renormalization of the quark-quark-W vertex by chirally enhanced supersymmetric self-energies has been computed. The results imply new bounds on the off-diagonal elements of the squark mass matrices if t’Hooft’s naturalness criterion is invoked. In this section we extend the analysis of 11 and calculate the leading contributions to the quark-quark-W vertex which decouple for $M_{\text{SUSY}} \to \infty$. Using the conventions of Ref. 11 we expand to first order in the external momenta and decompose the self-energies as

$$
\Sigma_{fi}^q = \left( \Sigma_{fi}^{LR} + \delta_\chi \Sigma_{fi}^{RR} \right) P_R + \left( \Sigma_{fi}^{RL} + \delta_\chi \Sigma_{fi}^{LL} \right) P_L.
$$

These self-energies lead to a flavor-valued wave-function renormalization $\Delta U_{fi}^{LR}$ for all external left- and right-handed fields. It is useful to decompose these factors further into an unphysical anti-Hermitian part $\Delta U_{fi}^{LA}$ which can be absorbed into the renormalization of the CKM matrix, and a Hermitian part $\Delta U_{fi}^{LR}$, which can constitute a physical effect appearing as a deviation from CKM unitarity: $\Delta U_{fi}^{LR,H} = \Sigma_{fi}^{LL,RR}/2$. Neglecting external momenta, the genuine vertex-correction originating from a squark-gluino loop is given by

$$
-i\lambda_{u,d} W_{st} \frac{g_2}{\sqrt{2}} \frac{i\alpha_s}{3\pi} \sum_{s,t=1}^6 \sum_{f=1}^3 \left( W_f^g W_{ks} W_{kj}^L W_{jt}^d \delta_{st} P_L + W_f^g W_{ks} W_{kj}^L W_{jt}^d \delta_{st} P_R \right) C_2 \left( m_{u,s}, m_{d,t}, m_{g} \right).
$$

The matrices $W_{st}^q$ diagonalize the squark mass matrices 11. The part proportional to $P_L$ in Eq. (7) cancels with the anti-Hermitian part of the wave-function renormalization due to the SU(2) relation between the left-handed up and down squarks for $M_{\text{SUSY}} \to \infty$ according to the decoupling theorem 2. Since the loop functions depend only weakly on $M_{\text{SUSY}}$, the cancellation is very efficient, even for light squarks around 300 GeV. Therefore, the unitarity of the CKM matrix is conserved with very high accuracy. A right-handed mixing of quarks to the W boson is induced by the diagram in Fig. 3 if left-right mixing of squarks is present. The effective coupling corresponds to $Q_{RR}$ in Eq. 2 and vanishes in the decoupling limit. There is no wave-function renormalization of right-handed quarks which can be applied to the W vertex, therefore no gauge cancellations occur.

We show the relative size of the right-handed coupling involving $u,c$ and $b$ in Fig. 4. Note that the mass insertion $\delta_{13,23}$ are not affected by the fine-tuning argument imposed in 11 nor severely restricted by FCNC processes 14. Therefore the size of the induced couplings $V_{tb}^{R}$ can be large enough to explain (attenuate) the apparent discrepancies among the various determinations of $|V_{ub}|$ and $|V_{cb}|$. Nevertheless, if $\delta_{13,23}^{RL}$ is large single-top production is enhanced which can be observed at the LHC 15. In principle also charged Higgs contributions to $B \to \tau\nu$ have to be considered in the MSSM. However, these contributions are only important in the special case in which both $\text{tan}(\beta)$ is large and the charged Higgs is light. Furthermore, a charged Higgs always interferes destructively with the SM, making the discrepancy between the different determinations of $V_{ub}$ even bigger.
IV. CONCLUSIONS

In this article we have first examined the effect of an effective right-handed coupling of quarks to the W boson on the determination of $|V_{ub}|$ and $|V_{cb}|$ from different decay modes. In both cases a right-handed coupling can improve the agreement among these determinations (Figs. 1 and 2). In particular, one can simultaneously remove the disturbing problem with $B \rightarrow \tau \nu$ and improve the agreement among inclusive and exclusive determinations of $|V_{ub}|$. Second, we have shown that a loop-induced right-handed coupling is generated within the MSSM if left-right mixing of squarks is present. This coupling has the right size needed to resolve the tensions in $|V_{ub}|$. Such a scenario involves a large left-right mixing between sbot-tos (as present in e.g. the popular large-$\tan \beta$ scenarios) and a large $A_{31}$-term which enhances single-top production, making it observable at the LHC. If $\delta_{31}^{RL} \approx 0.6$ a 95% CL signal can already be detected with 50 inverse femto-barn. In $b \rightarrow c$ transitions the loop-induced supersymmetric right-handed coupling can alleviate, but cannot fully remove, the discrepancies among the three methods to determine $|V_{cb}|$. To probe $b \rightarrow u$ transitions we propose to look for right-handed couplings in the differential decay distributions of $B \rightarrow \rho \ell \nu$. The smaller right-handed component in $b \rightarrow c$ transitions can be probably better studied in $B \rightarrow X_s \ell \nu$ than in $B \rightarrow D^* \ell \nu$ decays, because a theoretical control of form factors to percent accuracy is challenging.
