Abstract

Epoch gradient descent method (a.k.a. Epoch-GD) proposed by (Hazan and Kale, 2011) was deemed a breakthrough for stochastic strongly convex minimization, which achieves the optimal convergence rate of $O(1/T)$ with $T$ iterative updates for the objective gap. However, its extension to solving stochastic min-max problems with strong convexity and strong concavity still remains open, and it is still unclear whether a fast rate of $O(1/T)$ for the duality gap is achievable for stochastic min-max optimization under strong convexity and strong concavity. Although some recent studies have proposed stochastic algorithms with fast convergence rates for min-max problems, they require additional assumptions about the problem, e.g., smoothness, bi-linear structure, etc. In this paper, we bridge this gap by providing a sharp analysis of epoch-wise stochastic gradient descent ascent method (referred to as Epoch-GDA) for solving strongly convex strongly concave (SCSC) min-max problems, without imposing any additional assumptions about smoothness or its structure. To the best of our knowledge, our result is the first one that shows Epoch-GDA can achieve the fast rate of $O(1/T)$ for the duality gap of general SCSC min-max problems. We emphasize that such generalization of Epoch-GD for strongly convex minimization problems to Epoch-GDA for SCSC min-max problems is non-trivial and requires novel technical analysis. Moreover, we notice that the key lemma can be also used for proving the convergence of Epoch-GDA for weakly-convex strongly-concave min-max problems, leading to the best complexity as well without smoothness or other structural conditions.

1. Introduction

In this paper, we consider stochastic algorithms for solving the following min-max saddle-point problem with a general objective function $f$ without smoothness or any other special structure:

$$\min_{x \in X} \max_{y \in Y} f(x, y),$$

where $X \subseteq \mathbb{R}^d$ and $Y \subseteq \mathbb{R}^n$ are closed convex sets and $f : X \times Y \to \mathbb{R}$ is continuous. It is of great interest to find a saddle-point solution to the above problem, which is defined as
problem, where there exists $\rho > 0$ such that $f(x, y) + \frac{\rho}{2} \|x\|^2$ is strongly convex in terms of $x$ for any $y \in Y$ and is strongly concave in terms of $y$ for any $x \in X$; (ii) weakly-convex strongly-concave (WCSC) problem, where there exists $\rho > 0$ such that $f(x, y) + \frac{\rho}{2} \|x\|^2$ is strongly convex in terms of $x$ for any $y \in Y$ and is strongly concave in terms of $y$ for any $x \in X$. Both classes have applications in machine learning (Yan et al., 2019; Rafique et al., 2018).

In this work, we focus on two classes of the min-max problems: (i) strongly-convex strongly-concave (SCSC) problem where $f$ is strongly convex in terms of $x$ for any $y \in Y$ and is strongly concave in terms of $y$ for any $x \in X$; (ii) weakly-convex strongly-concave (WCSC) problem, where there exists $\rho > 0$ such that $f(x, y) + \frac{\rho}{2} \|x\|^2$ is strongly convex in terms of $x$ for any $y \in Y$ and is strongly concave in terms of $y$ for any $x \in X$. Both classes have applications in machine learning (Yan et al., 2019; Rafique et al., 2018).

Although stochastic algorithms for convex-concave min-max problems have been studied extensively in the literature, their research is still far behind its counterpart for stochastic convex minimization problems. Below, we highlight some of these gaps to motivate the present work. For the sake of presentation, we first introduce some terminologies. The duality gap at $(x, y)$ is defined as $\text{Gap}(x, y) := f(x, \hat{y}(x)) - f(\hat{x}(y), y)$, where $\hat{x}(y) := \arg\min_{x' \in X} f(x', y)$ and $\hat{y}(x) := \arg\max_{y' \in Y} f(x, y')$. If we denote by $P(x) := \max_{y' \in Y} f(x, y')$, then $P(x) - P(x^*)$ is the primal objective gap, where $x^* = \arg\min_{x \in X} P(x)$.

When $f$ is convex in $x$ and concave in $y$, many studies have designed and analyzed stochastic primal-dual algorithms for solving the min-max problems under different conditions of the problem (see references in next section). A standard result is provided by (Nemirovski et al., 2009), which proves that primal-dual SGD suffers from a convergence rate of $O(1/\sqrt{T})$ for the duality gap without imposing any additional assumptions about the objective function. This is analogous to that for stochastic convex minimization (Nemirovski et al., 2009). However, the research of stochastic algorithms for SCSC problems lacks behind that for strongly convex minimization problems. A well-known result for stochastic strongly convex minimization is given by (Hazan and Kale, 2011), which presents the first fast convergence rate $O(1/T)$ for stochastic strongly convex minimization by Epoch-GD algorithm, which runs standard SGD in an epoch-wise manner by decreasing the step size geometrically. However, a fast rate of $O(1/T)$ for the duality gap of a stochastic algorithm is still unknown for general SCSC problems. We notice that there are extensive studies about stochastic algorithms with faster convergence rates than $O(1/\sqrt{T})$ for solving convex-concave min-max problems (Zhang and Xiao, 2017; Tan et al., 2018; Shalev-Shwartz and Zhang, 2013; Du and Hu, 2018; Dang and Lan, 2014; Chen et al., 2014; Palaniappan and Bach, 2016; Hsieh et al., 2019; Yan et al., 2019; Hien et al., 2017; Zhao, 2019). However, these works usually require additional assumptions about the objective function (e.g., smoothness, bilinear structure) or only prove the convergence for weaker measures (e.g., the primal objective gap, the distance of a solution to the saddle point).

We aim to bridge this gap by presenting the first fast rate $O(1/T)$ of the duality gap for solving general SCSC problems. In particular, we propose an epoch-wise stochastic gradient ascent (Epoch-GDA) algorithm - a primal-dual variant of Epoch-GD that runs stochastic gradient descent update for the primal variable and stochastic gradient ascent update for the dual variable for solving (1). Although the algorithmic generalization is straightforward, the proof of convergence in terms of the duality gap for Epoch-GDA is not
Table 1: Summary of complexity results of this work and previous works for finding an $\epsilon$-duality-gap solution for SCSC or an $\epsilon$-stationary solution for WCSC min-max problems. We focus on comparison of existing results without assuming smoothness of the objective function. Restriction means whether additional condition about the objective function is imposed.

|         | This paper                                 | No          | Nearly Stationary   | $\tilde{O}\left(\frac{1}{\epsilon^4}\right)$ |

Straightforward at all. We note that the key difference in the analysis of Epoch-GDA is that to upper bound the duality gap of a solution $(\bar{x}, \bar{y})$ we need to deal with the distance of an initial solution $(x_0, y_0)$ to the reference solutions $(\hat{x}(\bar{y}), \hat{y}(\bar{x}))$, where $\hat{x}(\bar{y}) = \arg\min_{x' \in X} f(x', \bar{y})$ and $\hat{y}(\bar{x}) = \arg\max_{y' \in Y} f(\bar{x}, y')$ depend on $\bar{y}$ and $\bar{x}$, respectively. In contrast, in the analysis of the objective gap for Epoch-GD, one only needs to deal with the distance from an initial solution $x_0$ to the optimal solution $x^*$, i.e., $\|x_0 - x^*\|^2_2$, which by strong convexity can easily connects to the objective gap $P(x_0) - P(x^*)$, leading to the telescoping sum on the objective gap. Towards addressing the challenge caused by dealing with the duality gap, we present a key lemma that connects the distance measure $\|x_0 - \hat{x}(\bar{y})\|^2_2 + \|y_0 - \hat{y}(\bar{x})\|^2_2$ to the duality gap of $(x_0, y_0)$ and $(\bar{x}, \bar{y})$. In addition, since we use the same technique as Epoch-GD for handling the variance of stochastic gradient by projection onto a bounded ball with shrinking radius, we have to carefully prove that such restriction does not affect the duality gap for the original problem, which also needs to deal with bounding $\|x_0 - \hat{x}(\bar{y})\|^2_2$ and $\|y_0 - \hat{y}(\bar{x})\|^2_2$.

Moreover, we notice that the aforementioned key lemma and the telescoping technique based on the duality gap can be also used for proving the convergence of Epoch-GDA for finding an approximate stationary solution of general WCSC problems. The algorithmic framework is similar to that proposed by Rafique et al. (2018), i.e., by solving SCSC problems successively, but with subtle difference in handling the dual variable. In particular, we do not need additional condition on the structure of the objective function and extra care for dealing with the dual variable for restart as done in Rafique et al. (2018). This key difference is caused by our sharper analysis, i.e., we use the telescoping sum based on the duality gap instead of the primal objective gap as in (Rafique et al., 2018). As a result, our algorithm and analysis lead to the best complexity so far for solving WCSC problems without smoothness assumption of the objective. Finally, we summarize our results and the comparison with existing results in Table 1.
2. Related Work

There are extensive studies on stochastic algorithms for min-max problems in both mathematical programming and machine learning communities. Below, we provide an overview of related results in this area and the review is not necessarily exhaustive. In addition, we focus on the stochastic algorithms, and leave deterministic algorithms (Chambolle and Pock, 2011; Nesterov, 2005; Yang et al., 2015; Gidel et al., 2016; Nouiehed et al., 2019; Hong, 2016; Hajinezhad and Hong, 2019; Hong et al., 2018; Lu et al., 2019; Hamedani and Aybat, 2018) out of our discussion.

Nemirovski et al. (2009) is one of the early works that studies stochastic primal-dual gradient methods for convex-concave min-max problems, which establishes a convergence rate of $O(1/\sqrt{T})$ for the duality gap of general convex-concave problems. Following this work, many studies have tried to improve the algorithm and the analysis for certain class of problems by exploring the smoothness condition of some component functions (Juditsky et al., 2011; Zhao, 2019; Hsieh et al., 2019) or bilinear structure of the objective function (Chen et al., 2014; Dang and Lan, 2014). For example, Zhao (2019) considers a family of min-max problems whose objective is $f(x) + g(x) + \phi(x, y) - J(y)$, where smoothness condition is imposed on $f$ and $\phi$ and strong convexity is imposed on $f$ if necessary, and establishes optimal or near optimal complexity of a stochastic primal-dual hybrid algorithm. Although the dependence on each problem parameter of interest is made (near) optimal, the worst case complexity is still $O(1/\sqrt{T})$. Hsieh et al. (2019) considers single-call stochastic extra-gradient and establishes $O(1/T)$ rate for smooth and strongly monotone variational inequalities in terms of the square distance from the returned solution to the saddle point. The present work is complementary to these developments by making no assumption on smoothness or the structure of the problem but consider strong (weak) convexity and strong concavity of the objective function. It has applications in robust learning with non-smooth loss functions (Yan et al., 2019; Rafique et al., 2018).

In the machine learning community, many works have considered stochastic primal-dual algorithms for solving regularized loss minimization problems, whose min-max formulation usually exhibits bi-linear structure (Zhang and Xiao, 2017; Shalev-Shwartz and Zhang, 2013; Wang and Xiao, 2017; Du and Hu, 2018; Palaniappan and Bach, 2016). For example, Zhang and Xiao (2017) designed stochastic primal-dual coordinate (SPDC) method for SCSC problems with bilinear structure, which enjoys a linear convergence for the duality gap. Similarly, in (Yu et al., 2015; Tan et al., 2018), different variants of SPDC are proposed and analyzed for problems with the bilinear structure. Palaniappan and Bach (2016) proposed stochastic variance reduction methods for a family of saddle-point problems with special structure that yields a linear convergence rate. An exception that makes no smoothness assumption and imposes no bilinear structure is a recent work (Yan et al., 2019). They considered a family of functions $f(x, y) = y^T \ell(x) - \phi^*(y) + g(x)$ and proposed a stochastic primal-dual algorithm similar to Epoch-GDA. The key difference is that they designed a particular scheme that computes a restarting dual solution based on $\nabla \phi(\ell(\bar{x}))$, where $\bar{x}$ is a restarting primal solution in order to derive a fast rate of $O(1/T)$ under strong convexity and strong concavity. Additionally, their fast rate $O(1/T)$ is in terms of the primal objective gap, which is weaker than our convergence result in terms of the duality gap.
There is also increasing interest on stochastic primal-dual algorithms for solving WCSC min-max problems. To the best of our knowledge, Rafique et al. (2018) is probably the first work that comprehensively studies stochastic algorithms for solving WCSC min-max problems. To find a nearly $\epsilon$-stationary point, their algorithms suffer from an $O(1/\epsilon^6)$ iteration complexity without strong concavity and an $O(1/\epsilon^4 + n/\epsilon^2)$ complexity with strong concavity and a special structure of the objective function that is similar to that imposed in (Yan et al., 2019). Some recent works are trying to improve the complexity for solving WCSC min-max problems by exploring other conditions (e.g., smoothness) (Lin et al., 2019; Luo Luo, 2020). For example, Lin et al. (2019) established an $O(1/\epsilon^4)$ complexity for a single-loop stochastic gradient descent ascent method. However, their analysis requires smoothness condition and their algorithm needs to use a large mini-batch size in the order $O(1/\epsilon^2)$. In contrast, we impose neither assumption about smoothness nor special structure of the objective function. The complexity of our algorithm is $O(1/\epsilon^4)$ for finding a nearly $\epsilon$-stationary point, which is the state of the art result for the considered problem.

3. Preliminaries

This section provides some notations and assumptions used in the paper. We let $\| \cdot \|$ denote the Euclidean norm of a vector. Given a function $f : \mathbb{R}^d \rightarrow \mathbb{R}$, we denote the Fréchet subgradients and limiting Fréchet gradients by $\hat{f}$ and $\partial f$ respectively, i.e., at $x$, $\hat{f}(x) = \{ v \in \mathbb{R}^d : \lim_{x \rightarrow x'} \inf_{x' \in X} \frac{f(x) - f(x') - v^\top (x-x')}{\|x-x'\|} \geq 0 \}$, and $\partial f(x) = \{ v_k \in \mathbb{R}^d : \exists x_k \xrightarrow{f} x, v_k \xrightarrow{f} v, v \in \hat{f}(x) \}$. Here $x_k \xrightarrow{f} x$ represents $x_k \rightarrow x$ with $f(x_k) \rightarrow f(x)$. A function $f(x)$ is $\mu$-strongly convex on $X$ if for any $x, x' \in X$, $\partial f(x')^\top (x-x') + \frac{\mu}{2}\|x-x'\|^2 \leq f(x) - f(x')$. A function $f(x)$ is $\rho$-weakly convex on $X$ for any $x, x' \in X$ $\partial f(x')^\top (x-x') - \frac{\rho}{2}\|x-x'\|^2 \leq f(x) - f(x')$. Let $G_x = \partial_x f(x; y; \xi)$ denote a stochastic subgradient of $f$ at $x$ given $y$, where $\xi$ is used to denote the random variable. Similarly, let $G_y = \partial_y f(x; y; \xi)$ denote a stochastic subgradient of $f$ at $y$ given $x$. Let $\Pi_{\Omega}[\cdot]$ denote the projection onto the set $\Omega$, and let $B(x, R)$ denotes an Euclidean ball centered at $x$ with a radius $R$. Denote by $\text{dist}(x, X)$ the distance between $x$ and the set $X$, i.e., $\text{dist}(x, X) = \min_{v \in X} \|x-v\|$. Let $\hat{O}(\cdot)$ hide some logarithmic factors.

For a WCSC min-max problem, it is generally a hard problem to find a saddle point. Hence, we use nearly $\epsilon$-stationarity as the measure of convergence for solving WCSC problems (Rafique et al., 2018), which is defined as follows.

**Definition 1** A solution $x$ is a nearly $\epsilon$-stationary point of $\min_x \psi(x)$ if there exists $z$ and a constant $c > 0$ such that $\|z-x\| \leq ce$ and $\text{dist}(0, \partial \psi(z)) \leq \epsilon$.

For a $\rho$-weakly convex function $\psi(x)$, let $z = \arg \min_{x \in \mathbb{R}^d} \psi(x) + \frac{\gamma}{2}\|x-\tilde{x}\|^2$ where $\gamma > \rho$ and $\tilde{x} \in \mathbb{R}^d$ is a reference point. Due to the strong convexity of the above problem, $z$ is unique and $0 \in \partial \psi(z) + \gamma(z-\tilde{x})$, which results in $\gamma(\tilde{x}-z) \in \partial \psi(z)$, so that $\text{dist}(0, \partial \psi(z)) \leq \gamma \|\tilde{x}-z\|$. We can find a nearly $\epsilon$-stationary point $\tilde{x}$ as long as $\gamma \|\tilde{x}-z\| \leq \epsilon$.

Before ending this section, we present some assumptions that will be imposed in our analysis.

**Assumption 1** $X$ and $Y$ are closed convex sets. There exists initial solutions $x_0 \in X, y_0 \in Y$ and $\epsilon_0 > 0$ such that $\text{Gap}(x_0, y_0) \leq \epsilon_0$.

Algorithm 1 Epoch-GDA for SCSC Min-Max Problems

1: Init.: $x_0 = x_0 \in X$, $y_0 = y_0 \in Y$, $\eta_x, \eta_y, R_1, T_1$
2: for $k = 1, 2, \ldots, K$ do
3: for $t = 0, 1, 2, \ldots, T_k - 1$ do
4: Compute stochastic gradients $G_{x,t}^k = \partial_x f(x_t^k, y_t^k; \xi_t^k)$ and $G_{y,t}^k = \partial_y f(x_t^k, y_t^k; \xi_t^k)$.
5: $x_{t+1}^k = \Pi_{X \cap B(x_0^k, R_k)}(x_t^k - \eta_x G_{x,t}^k)$
6: $y_{t+1}^k = \Pi_{Y \cap B(y_0^k, R_k)}(y_t^k + \eta_y G_{y,t}^k)$
7: end for
8: $x_{0}^{k+1} = \frac{1}{T_k} \sum_{t=0}^{T_k-1} x_t^k$, $y_{0}^{k+1} = \frac{1}{T_k} \sum_{t=0}^{T_k-1} y_t^k$
9: $\bar{x}_k = \frac{y_{0}^{k+1}}{2}$, $\bar{y}_k = \frac{y_{0}^{k+1}}{2}$, $R_{k+1} = R_k / \sqrt{2}$, $T_{k+1} = 2T_k$
10: end for
11: Return $(\bar{x}_K, \bar{y}_K)$.

Assumption 2 (1) $f(x, y)$ is $\mu$-strongly convex in $x$ for any $y \in Y$ and $\lambda$-strongly concave in $y$ for any $x \in X$. (2) there exist $B_1, B_2 > 0$ such that $\mathbb{E}[\exp(\|G_x\|^2)] \leq \exp(1)$ and $\mathbb{E}[\exp(\|G_y\|^2)] \leq \exp(1)$.

Assumption 3 (1) $f(x, y)$ is $\rho$-weakly convex in $x$ for any $y \in Y$ and is $\lambda$-strongly concave in $y$ for any $x \in X$. (2) $\mathbb{E}[\|G_x\|^2] \leq M_1^2$ and $\mathbb{E}[\|G_y\|^2] \leq M_2^2$.

4. Main Results

4.1. Strongly-Convex Strongly-Concave Min-Max Problems

In this subsection, we present the main result for solving SCSC problems. The proposed Epoch-GDA algorithm for SCSC min-max problems is shown in Algorithm 1. As illustrated, our algorithm consists of a series of epochs. In each epoch (Line 3 to 7), standard primal-dual updates are performed. After an epoch ends, in Line 8, the solutions $\bar{x}_k$ and $\bar{y}_k$ averaged over the epoch are returned as the initialization for the next epoch. In Line 9, step sizes $\eta_{x,k+1}$ and $\eta_{y,k+1}$, the radius $R_{k+1}$ and the number of iterations $T_{k+1}$ are also adjusted for the next epoch. The ball constraints $B(x_0^k, R_k)$ and $B(y_0^k, R_k)$ at each iteration are used for the convergence analysis in high probability as in (Hazan and Kale, 2011, 2014). It is clear that Epoch-GDA can be considered as a primal-dual variant of Epoch-GD (Hazan and Kale, 2011, 2014).

The following theorem shows that the iteration complexity of Algorithm 1 to achieve an $\epsilon$-duality gap for a general SCSC problem (1) is $O(1/\epsilon)$.

Theorem 1 Suppose Assumption 1 and Assumption 2 hold and let $\delta \in (0, 1)$ be a failing probability and $\epsilon \in (0, 1)$ be the target accuracy level for the duality gap. Let $K = \lceil \log(\delta/\epsilon) \rceil$ and $\bar{\delta} = \delta/K$, and the initial parameters are set by $R_1 \geq 2 \sqrt{\frac{2\epsilon_0}{\min\{\mu, \lambda\}}} \eta_x^1 = \frac{\min\{\mu, \lambda\} R_1^2}{40(5 + 3 \log(1/\bar{\delta})) B_1^2}$. 

Algorithm 2 Epoch-GDA for WCSC Min-Max Problems

1: Init.: $x_0^1 = x_0 \in X, y_0^1 = y_0 \in Y, \gamma = 2\rho$.
2: for $k = 1, 2, ..., K$ do
3: \hspace{1em} Set $T_k = \frac{106(k+1)}{3}, \eta_x^k = \frac{4}{\rho(k+1)}, \eta_y^k = \frac{2}{\lambda(k+1)}$.
4: \hspace{1em} for $t = 1, 2, ..., T_k$ do
5: \hspace{2em} Compute $G_{x,t}^k = \partial_x f(x_t^k, y_t^k, \xi_t^k)$ and $G_{y,t}^k = \partial_y f(x_t^k, y_t^k, \xi_t^k)$.
6: \hspace{2em} $x_{t+1}^k = \arg \min_{x \in X} x^\top G_{x,t}^k + \frac{1}{2\eta_x^k}||x - x_t^k||^2 + \frac{\gamma}{2}||x - x_0^k||^2$
7: \hspace{2em} $y_{t+1}^k = \arg \min_{y \in Y} y^\top G_{y,t}^k + \frac{1}{2\eta_y^k}||y - y_t^k||^2$
8: \hspace{1em} end for
9: $x_{0}^{k+1} = \bar{x}_k = \frac{1}{T} \sum_{t=0}^{T-1} x_t^k, y_{0}^{k+1} = \bar{y}_k = \frac{1}{T} \sum_{n=0}^{T-1} y_t^k$
10: end for
11: Return $x_0^*$ by $\tau$ randomly sampled from $\{1, ..., K\}$.

\[
\eta_y^1 = \frac{\min\{\mu, \lambda\} R_2^2}{40(5 + 3\log(1/\delta))B_2^2} \quad \text{and} \quad T_1 \geq \frac{\max\left\{320^2(B_1 + B_2)^2 3\log(1/\delta), 3200(5 + 3\log(1/\delta)) \max\{B_1^2, B_2^2\}\right\}}{\min\{\mu, \lambda\} 2^2 R_1^2}
\]

Then the total number of iterations of Algorithm 1 to achieve $\epsilon$-duality gap, i.e., $\text{Gap}({\bar{x}_K, \bar{y}_K}) \leq \epsilon$, with probability $1 - \delta$ is

\[
T_{\text{tot}} = \frac{\max\left\{320^2(B_1 + B_2)^2 3\log(1/\delta), 3200(5 + 3\log(1/\delta)) \max\{B_1^2, B_2^2\}\right\}}{4 \min\{\mu, \lambda\} \epsilon}
\]

Remark 1 To the best of our knowledge, this is the first study that achieves a fast rate of $O(1/T)$ for the duality gap of a general SCSC min-max problem without special structure assumption or smoothness of the objective function and additional computational cost. In contrast, even if the algorithm in (Yan et al., 2019) attains the $O(1/T)$ rate of convergence, it (i) only guarantees the convergence of the primal objective gap, rather than the duality gap, (ii) additionally requires a special structure of the objective function, and (iii) needs extra $\tilde{O}(n)$ computational cost of the deterministic update at each outer loop to handle the maximization over $y$. In contrast, Algorithm 1 has stronger theoretical results with less restrictions of problem structures and computational cost.

Remark 2 A lower bound of $O(1/T)$ for stochastic strongly convex minimization problems has been proved in (Agarwal et al., 2009; Hazan and Kale, 2014). Due to $\text{Gap}(x,y) \geq P(x) - P(x^*)$, bounding duality gap is more difficult than bounding primal gap. This means that our convergence rate matches the lower bound and is therefore the best possible convergence rate without adding more assumptions.

4.2. Weakly-Convex Strongly-Concave Problems

In this subsection, we present the convergence results for solving WCSC problems, where the objective function $f(x, y)$ in (1) is $\rho$-weakly convex in $x$ and $\lambda$-strongly concave in $y$. The proposed Epoch-GDA algorithm for WCSC min-max problems is summarized in Algorithm 2. As our Algorithm 1, Algorithm 2 consists of a number of epochs. As shown in Line 4
to Line 8, each epoch performs primal-dual updates on $x$ and $y$. When updating $x$ at the $k$-th stage, an additional regularizer $\frac{\gamma}{2} \|x - x_0^k\|^2$ is added, where the value of $\gamma = 2\rho$. The added term is used to handle the weak convexity condition. After an epoch ends, average solutions of both $x$ and $y$ are restarted as the initial ones for the next epoch. The step sizes for updating $x$ and $y$ are set to $O(1/(\rho k))$ and $O(1/(\lambda k))$ at the $k$-th epoch, respectively. If we define $f_k(x, y) = f(x, y) + \frac{\gamma}{2} \|x - x_0^k\|^2$, we can see that $f_k(x, y)$ is $\rho$-strongly convex in $x$ and $\lambda$-strongly concave in $y$, since $f(x, y)$ is $\rho$-weakly convex and $\gamma = 2\rho$. Indeed, for each inner loop of Algorithm 2, we actually work on the SCSC problem $\min_{x \in X} \max_{y \in Y} \hat{f}_k(x, y)$.

It is worth mentioning the key difference between our algorithm and the recently proposed stochastic algorithm PG-SMD (Rafique et al., 2018) for WCSC problems with a special structural objective function. PG-SMD also consists of two loops. For each inner loop, it runs the same updates with the added regularizer on $x$ as Algorithm 2. It restarts $x$ by averaging the solutions over the inner loop, like our $\bar{x}_k$, but restarts $y$ by taking the deterministic maximization of (1) over $y$ given $\bar{x}_k$, leading to an additional $O(n)$ computational complexity per epoch. In addition, PG-SMD sets $\eta_k^x = O(1/(\gamma \lambda^2 k))$. Although Algorithm 2 shares similar updates with PG-SMD, our analysis yields stronger results under weaker assumptions — the same iteration complexity $\tilde{O}(1/\epsilon^4)$ without deterministic updates for $y$ and special structure in the objective function. This is due to our sharper analysis that makes use of telescoping sum based on the duality gap of $\hat{f}_k$ instead of the primal objective gap.

The convergence result of Algorithm 2 that achieves a nearly $\epsilon$-stationary point with $\tilde{O}(1/\epsilon^4)$ iteration complexity is summarized below.

**Theorem 2** Suppose Assumption 3 holds. Algorithm 2 guarantees

$$E[\text{dist}(0, \partial P(\hat{x}_r^*))^2] \leq \gamma^2 E[\|\hat{x}_r^* - \hat{x}_0^r\|^2] \leq \epsilon^2$$

after $K = \max \left\{ \frac{1696(2M^2 + M^2)}{\epsilon^2}, \frac{1696(2M^2 + M^2)}{\lambda^2}, \frac{1376\gamma^2}{5\epsilon^2} \right\}$, where $\tau$ randomly sampled from $\{1, ..., K\}$ and $(\hat{x}_{k}^*, \hat{y}_{k})$ is the saddle-point of $f_k(x, y)$. The total number of iteration is $\sum_{k=1}^{K} T_k = \tilde{O}(\frac{1}{\epsilon^4})$.

**Remark 3** Theorem 2 shows that the iteration complexity of Algorithm 2 to attain an $\epsilon$-nearly stationary point is $\tilde{O}(1/\epsilon^4)$. It improves the result of (Rafique et al., 2018) for WCSC problems in terms of two aspects. First, (Rafique et al., 2018) requires a stronger condition on the structure of the objective function is present, while our analysis simply assumes a general objective function $f(x, y)$. Second, (Rafique et al., 2018) requires to solve the maximization over $y$ at each epoch, which may introduce $O(n)$ computational complexity for $y \in \mathbb{R}^n$. In contrast, our algorithm restarts both the primal variable $x$ and dual variable $y$ at each epoch that does not need additional cost.

5. Analysis

As we mentioned at the introduction, the key challenge in the analysis of Epoch-GDA lies at handling the variable distance measure $\|\hat{x}(y_1) - x_0\|^2 + \|\hat{y}(x_1) - y_0\|^2$ for any $(x_0, y_0) \in X \times Y$ and $(x_1, y_1) \in X \times Y$ and its connection to the duality gaps, where $\hat{x}(y_1) = \hat{y}(x_1)$. 

8
arg \min_{x' \in X} f(x', y_1) \text{ and } \hat{y}(x_1) = \arg \max_{y' \in Y} f(x_1, y'). \text{ Hence, we first introduce the following key lemma that is useful in the analysis of Epoch-GDA for both SCSC and WCSC problems. It connects the variable distance measure } ||\hat{x}(y_1) - x_0||^2 + ||\hat{y}(x_1) - y_0||^2 \text{ to the duality gaps at } (x_0, y_0) \text{ and } (x_1, y_1).

**Lemma 1** Consider the following \(\mu\)-strongly convex in \(x\) and \(\lambda\)-strongly concave problem

\[
\min_{x \in \Omega_1} \max_{y \in \Omega_2} f(x, y).
\]

Let \((x^*, y^*)\) denote the saddle point solution to this problem. Suppose we have two solutions \((x_0, y_0) \in \Omega_1 \times \Omega_2\) and \((x_1, y_1) \in \Omega_1 \times \Omega_2\). Then the following relation between variable distance and duality gaps holds

\[
\frac{\mu}{4} ||\hat{x}(y_1) - x_0||^2 + \frac{\lambda}{4} ||\hat{y}(x_1) - y_0||^2 \leq \max_{y' \in \Omega_2} f(x_0, y') - \min_{x' \in \Omega_1} f(x', y_0)
+ \max_{y' \in \Omega_2} f(x_1, y') - \min_{x' \in \Omega_1} f(x', y_1).
\]

(2)

**5.1. Proof of Theorem 1 for the SCSC setting**

The key idea is to first show the convergence of duality gap with respect to the ball constraints \(B(x_0^k, R_k)\) and \(B(y_0^k, R_k)\) in an epoch (Lemma 2). Then we investigate the condition to make \(\hat{x}(y_k) \in B(x_0^k, R_k)\) and \(\hat{y}(x_k) \in B(y_0^k, R_k)\) given the average solution \((\bar{x}_k, \bar{y}_k)\), which allows us to derive the duality gap \(\text{Gap}(\bar{x}_k, \bar{y}_k)\) for the original problem. Finally, under such conditions, we show how duality gap between two consecutive outer loops can be halved (Theorem 3), which implies the total iteration complexity (Theorem 1).

**Lemma 2** Suppose Assumption 2 holds. Let Line 3 to 7 of Algorithm 1 run for \(T\) iterations (omitting the \(k\)-index) by fixed step size \(\eta_x\) and \(\eta_y\). Then with the probability at least \(1 - \delta\) where \(0 < \delta < 1\), for any \(x \in X \cap B(x_0, R)\) and \(y \in Y \cap B(y_0, R)\), we have

\[
f(\bar{x}, y) - f(x, \bar{y}) \leq \frac{||x - x_0||^2}{\eta_x T} + \frac{||y - y_0||^2}{\eta_y T} + \frac{\eta_x B_1^2}{2} (5 + 3 \log(1/\delta)) + \frac{\eta_y B_2^2}{2} (5 + 3 \log(1/\delta))
+ \frac{4(B_1 + B_2)R \sqrt{3 \log(1/\delta)}}{\sqrt{T}}.
\]

(3)

where \(\bar{x} = \sum_{t=0}^{T-1} x_t / T\), \(\bar{y} = \sum_{t=0}^{T-1} y_t / T\).

**Remark 4** Lemma 2 is standard analysis for an epoch of Algorithm 1. The difficulty arises when attempting to plug \(x\) and \(y\) into (3). In order to derive the duality gap on the LHS of (3), we have to plug in \(x \leftarrow \hat{x}(\bar{y})\) and \(y \leftarrow \hat{y}(\bar{x})\). Nevertheless, it is unclear whether \(\hat{x}(\bar{y}) \in B(x_0, R)\) and \(\hat{y}(\bar{x}) \in B(y_0, R)\), which is the requirement for \(x\) and \(y\) to be plugged into (3). In the following lemma, we investigate the condition to make \(\hat{x}(\bar{y}) \in B(x_0, R)\) and \(\hat{y}(\bar{x}) \in B(y_0, R)\) based on Lemma 1.

**Lemma 3** Suppose Assumption 2 holds. Let \(\hat{x}_R(y) := \arg \min_{x \in X \cap B(x_0, R)} f(x, y)\) and \(\hat{y}_R(x) := \arg \max_{y \in Y \cap B(y_0, R)} f(x, y)\). Assume the initial duality gap \(\text{Gap}(x_0, y_0) \leq \epsilon_0\). Let Lines 3 to 7 of Algorithm 1 run \(T\) iterations with \(\delta \in (0, 1)\), \(R \geq 2 \sqrt{\frac{2 \epsilon_0}{\min\{\mu, \lambda\}}}\), \(\eta_x = \frac{\mu}{2} R \lambda^{1/2}\).
\[
\eta_y = \min\{\mu, \lambda\} R^2, \quad \eta_R = \min\{\mu, \lambda\} R^2
\]

\[
T \geq \frac{\max\left\{320^2(B_1 + B_2)^2 3 \log(1/\delta), 3200(5 + 3 \log(1/\delta)) \max\{B_1^2, B_2^2\}\right\}}{\mu^2 R^2}
\]

Then, with probability at least \(1 - \tilde{\delta}\), we have the following results:
\[
\|\bar{x}_R(y) - x_0\| < R, \quad \|\bar{y}_R(x) - y_0\| < R.
\]

**Remark 5** Lemma 3 shows that if we properly set the values of \(R, \eta_x, \eta_y, \text{and} T\), then \(\bar{x}_R(y)\) and \(\bar{y}_R(x)\) are the interior points of \(\mathcal{B}(x_0, R)\) and \(\mathcal{B}(y_0, R)\) with high probability. Therefore, we conclude that \(\hat{x}(y) = \bar{x}_R(y)\) and \(\hat{y}(x) = \bar{y}_R(x)\) with probability \(1 - \tilde{\delta}\) under the conditions of Lemma 3, which allows us to derive duality gap in LHS of (3) of Lemma 2.

The following theorem gives the relation of duality gaps between two consecutive epochs of Algorithm 1 by using Lemma 2 and the conditions proved by Lemma 3.

**Theorem 3** Consider the \(k\)-th epoch of Algorithm 1 with an initial solution \((x_0^k, y_0^k)\) and the ending averaged solution \((\bar{x}_k, \bar{y}_k)\). Suppose Assumption 2 holds and \(\text{Gap}(x_0^k, y_0^k) \leq \epsilon_{k-1}\). Let \(R_k \geq 2\sqrt{\frac{2\epsilon_{k-1}}{\min\{\mu, \lambda\}}}\) (i.e. \(\epsilon_{k-1} \leq \frac{\min\{\mu, \lambda\} R^2}{8}\)), \(\eta_x^k = \frac{\min\{\mu, \lambda\} R^2}{40(5 + 3 \log(1/\delta)) B_1^2}\), \(\eta_y^k = \frac{\min\{\mu, \lambda\} R^2}{40(5 + 3 \log(1/\delta)) B_2^2}\) and

\[
T_k \geq \frac{\max\left\{320^2(B_1 + B_2)^2 3 \log(1/\delta), 3200(5 + 3 \log(1/\delta)) \max\{B_1^2, B_2^2\}\right\}}{\min\{\mu, \lambda\}^2 R_k^2}
\]

Then we have with probability \(1 - \tilde{\delta}\), \(\text{Gap}(\bar{x}_k, \bar{y}_k) \leq \frac{\min\{\mu, \lambda\} R^2}{16}\).

**Remark 6** Theorem 3 shows that after running \(T_k\) iterations at the \(k\)-th stage, the upper bound of the duality gap would be halved with high probability, i.e., from \(\frac{\min\{\mu, \lambda\} R_k^2}{8}\) to \(\frac{\min\{\mu, \lambda\} R_k^2}{16}\). Then, in order to make the duality gap of each outer loop of Algorithm 1 halved from the last epoch, we can simply set \(R_{k+1}^2 = \frac{R_k^2}{2}\), and accordingly, \(\eta_{x,k+1} = \frac{\eta_x^k}{2}\), \(\eta_{y,k+1} = \frac{\eta_y^k}{2}\) and \(T_{k+1} = 2T_k\).

**Proof** (of Theorem 3) For any \(x \in \mathcal{B}(x_0^k, R_k)\) and \(y \in \mathcal{B}(y_0^k, R_k)\), we have \(\|x - x_0^k\| \leq R\) and \(\|y - y_0^k\| \leq R\), so by (3) of Lemma 2, we have with probability \(1 - \tilde{\delta}\)

\[
f(\bar{x}_k, y) - f(x, \bar{y}_k) \leq \frac{R_k^2}{\eta_x^k T_k} + \frac{R_k^2}{\eta_y^k T_k} + \frac{\eta_x^k B_2^2}{2}(5 + 3 \log(1/\delta)) + \frac{\eta_y^k B_2^2}{2}(5 + 3 \log(1/\delta))
\]

\[
+ \frac{4(B_1 + B_2) R_k \sqrt{3 \log(1/\delta)}}{\sqrt{T_k}} \leq \frac{\min\{\mu, \lambda\} R_k^2}{16},
\]

where inequality (a) is due to \(x \in \mathcal{B}(x_0^k, R_k)\) and \(y \in \mathcal{B}(y_0^k, R_k)\). Inequality (b) is due to the values of \(\eta_x^k, \eta_y^k\) and \(T_k\). Recall the definitions \(\hat{x}(\bar{y}_k) = \arg\min_{x \in \mathcal{X}} f(x, \bar{y}_k)\) and \(\hat{y}(\bar{x}_k) = \arg\max_{y \in \mathcal{Y}} f(\bar{x}_k, y)\). By Lemma 3, we have \(\hat{x}(\bar{y}_k) \in \mathcal{B}(x_0^k, R_k)\) and \(\hat{y}(\bar{x}_k) \in \mathcal{B}(y_0^k, R_k)\) with probability \(1 - \tilde{\delta}\). Then from (4) we have

\[
\text{Gap}(\bar{x}_k, \bar{y}_k) = \max_{y \in \mathcal{Y}} f(\bar{x}_k, y) - \min_{x \in \mathcal{X}} f(x, \bar{y}_k) \leq \frac{\min\{\mu, \lambda\} R_k^2}{16}.
\]
Given the condition \( \text{Gap}(x^k_0, y^k_0) \leq \epsilon_{k-1} \leq \frac{\min\{\mu, \lambda\} R^2}{8} \), we then conclude that running \( T_k \) iterations in an epoch of Algorithm 1 would halve the duality gap with high probability. As indicated in Theorem 3, the duality gap \( \text{Gap}(\hat{x}_k, \bar{y}_k) \) can be halved as long as the condition of Theorem 3 holds. Then Theorem 1 is implied (detailed proof is in Appendix).

5.2. Proof of Theorem 2 for the WCSC setting

Recall \( \hat{f}_k(x, y) = f(x, y) + \frac{\tau}{2} \|x - x^k_0\|^2 \). Let us denote its duality gap by \( \hat{\text{Gap}}_k(x, y) = \hat{f}_k(x, \hat{y}_k(x)) - \hat{f}_k(\hat{x}_k(y), y) \), where we define \( \hat{y}_k(x) := \arg\max_{y \in Y} \hat{f}_k(x, y') \) given \( x \in X \) and \( \hat{x}_k(y) := \arg\min_{x' \in X} \hat{f}_k(x', y) \) given \( y \in Y \). Its saddle point solution is denoted by \((\hat{x}_k^*, \hat{y}_k^*)\), i.e., \( \hat{f}_k(\hat{x}_k^*, \hat{y}_k^*) \leq \hat{f}_k(\hat{x}_k^*, y^k_0) \leq \hat{f}_k(x, \hat{y}_k^*) \) for any \( x \in X \) and \( y \in Y \). The key idea of our analysis is to connect the duality gap \( \hat{\text{Gap}}_k(x^k_0, y^k_0) \) to \( \gamma^2 \|\hat{x}_k^* - x^k_0\|^2 \), and then by making \( \gamma^2 \|\hat{x}_k^* - x^k_0\|^2 \leq \epsilon^2 \), we can show that \( x^k_0 \) is a nearly \( \epsilon \)-stationary point. Specifically, we first prove the result of the duality gap for the regularized problem \( \hat{f}_k(x, y) \) for the \( k \)-th epoch (Lemma 4). Then we extract \( \gamma \|\hat{x}_k^* - x^k_0\|^2 \) from the duality gap \( \hat{\text{Gap}}_k(x^k_0, y^k_0) \) (Lemma 5). Finally, we show how to make \( \gamma^2 \mathbb{E}[\|\hat{x}_k^* - x^k_0\|^2] \leq \epsilon^2 \) for \( \tau \) randomly sampled from \( \{1, ..., K\} \) (Theorem 2).

Lemma 4 Suppose Assumption 3 holds and \( \gamma = 2\rho \). For \( k \geq 1 \), Lines 4 to 8 of Algorithm 2 guarantee

\[
\mathbb{E}[\hat{\text{Gap}}_k(\hat{x}_k, \hat{y}_k)] = \mathbb{E}[\max_{x \in X} \hat{f}_k(\hat{x}, y) - \min_{x \in X} \hat{f}_k(x, y)] = \mathbb{E}[\hat{f}_k(\hat{x}_k, \hat{y}_k(\hat{x}_k)) - \hat{f}_k(\hat{x}_k(\hat{y}_k), \hat{y}_k)]
\leq \frac{5\eta^k_0 M^2}{2} + \frac{5\eta^k_0 M^2}{2} + \frac{1}{T_k} \left( \frac{1}{\eta^k_0} + \frac{\rho}{2} \right) \mathbb{E}[\|\hat{x}_k(\hat{y}_k) - x^k_0\|^2] + \frac{1}{\eta^k_0} \mathbb{E}[\|\hat{y}_k(\hat{x}_k) - y^k_0\|^2].
\] (5)

For RHS of (5), particularly, due to \( k \geq 1 \), \( T_k = \frac{106(k+1)}{4} \), \( \eta^k_0 = \frac{4}{\rho(k+1)} \) and \( \eta^k_0 = \frac{2}{\lambda(k+1)} \) in Algorithm 2, we have \( \frac{1}{T_k} \left( \frac{1}{\eta^k_0} + \frac{\rho}{2} \right) \leq \frac{36}{212} \) and \( \frac{1}{\eta^k_0} = \frac{3\lambda}{212} \). Then for the last two terms in the RHS of (5), we could have the following upper bound by the key lemma (Lemma 1)

\[
\frac{3}{53} \left( \frac{\rho}{4} \|\hat{x}_k(\hat{y}_k) - x^k_0\|^2 + \frac{\lambda}{4} \|\hat{y}_k(\hat{x}_k) - y^k_0\|^2 \right) \leq \frac{3}{53} \left( \hat{\text{Gap}}_k(x^k_0, y^k_0) + \hat{\text{Gap}}_k(\hat{x}_k, \hat{y}_k) \right).
\] (6)

On the other hand, the following lemma lower bounds LHS of (5) to construct telescoping sums.

Lemma 5 We could derive the following lower bound for \( \hat{\text{Gap}}_k(\hat{x}_k, \hat{y}_k) \)

\[
\hat{\text{Gap}}_k(\hat{x}_k, \hat{y}_k) \geq \frac{3}{50} \hat{\text{Gap}}_{k+1}(x^{k+1}_0, y^{k+1}_0) + \frac{4}{5} (P(x^{k+1}_0) - P(x^k_0)) + \frac{\gamma}{80} \|x^k_0 - \hat{x}_k^*\|^2.
\] (7)

Lemma 5 lower bounds \( \hat{\text{Gap}}_k(\hat{x}_k, \hat{y}_k) \) in LHS of (5) by three parts. The first part constructs telescoping sum of \( \hat{\text{Gap}}_{k+1}(x^{k+1}_0, y^{k+1}_0) - \hat{\text{Gap}}_k(x^k_0, y^k_0) \) together with (6). The second part itself is an element of telescoping sums over the primal gap. The third part \( \|x^k_0 - \hat{x}_k^*\|^2 \) can be used as the measure of nearly \( \epsilon \)-stationary point, which is further explored in Theorem 2.
Proof (of Theorem 2) Consider the $k$-th stage. Let us start from (5) in Lemma 4 as follows
\[
E[\text{Gap}_k(\hat{x}_k, \hat{y}_k)] \\
\leq \frac{5\eta_k^2 M_1^2}{2} + \frac{5\eta_y^2 M_2^2}{2} + \frac{1}{T_k}\left\{ \left( \frac{1}{\eta_x} + \frac{\rho}{2} \right) E[\|\hat{x}_k(\hat{y}_k) - x_0^k\|^2] + \frac{1}{\eta_y} E[\|\hat{y}_k(\hat{x}_k) - y_0^k\|^2] \right\}
\]
\[
\leq \frac{5\eta_k^2 M_1^2}{2} + \frac{5\eta_y^2 M_2^2}{2} + \frac{3}{53} \left( \frac{\rho}{4} E[\|\hat{x}_k(\hat{y}_k) - x_0^k\|^2] + \frac{\lambda}{4} E[\|\hat{y}_k(\hat{x}_k) - y_0^k\|^2] \right)
\]
\[
\leq \frac{5\eta_k^2 M_1^2}{2} + \frac{5\eta_y^2 M_2^2}{2} + \frac{3}{53} E[\text{Gap}_k(x_0^k, y_0^k)] + \frac{3}{53} E[\text{Gap}_k(\hat{x}_k, \hat{y}_k)],
\]
where (a) is due to settings $T_k = \frac{106(k+1)}{3}, \eta_x^k = \frac{4}{\rho(k+1)}$, and $\eta_y^k = \frac{2}{\lambda(k+1)}$. Re-organizing the above inequality, we have
\[
\frac{50}{53} E[\text{Gap}_k(\hat{x}_k, \hat{y}_k)] \leq \frac{5\eta_k^2 M_1^2}{2} + \frac{5\eta_y^2 M_2^2}{2} + \frac{3}{53} E[\text{Gap}_k(x_0^k, y_0^k)].
\]
Then for the LHS of (8), we apply (7) of Lemma 5 as follows
\[
\frac{50}{53} \left( \frac{3}{50} \text{Gap}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{4}{5} (P(x_0^{k+1}) - P(x_0^k)) + \frac{\gamma}{80} \|x_0^k - \hat{x}_k^k\|^2 \right)
\leq \frac{5\eta_k^2 M_1^2}{2} + \frac{5\eta_y^2 M_2^2}{2} + \frac{3}{53} E[\text{Gap}_k(x_0^k, y_0^k)].
\]
Next we have
\[
\frac{5\gamma}{424} E[\|x_0^k - \hat{x}_k^k\|^2] \leq \frac{5\eta_k^2 M_1^2}{2} + \frac{5\eta_y^2 M_2^2}{2} + \frac{40}{53} E[P(x_0^k) - P(x_0^{k+1})]
\]
\[
+ \frac{3}{53} \left( E[\text{Gap}_k(x_0^k, y_0^k)] - E[\text{Gap}_{k+1}(x_0^{k+1}, y_0^{k+1})] \right)
\]
Summing from $k = 1$ to $k = K$, we have
\[
\frac{5\gamma}{424} \sum_{k=1}^K E[\|x_0^k - \hat{x}_k^k\|^2] \leq \sum_{k=1}^K \frac{5\eta_k^2 M_1^2}{2} + \sum_{k=1}^K \frac{5\eta_y^2 M_2^2}{2} + \frac{40}{53} \sum_{k=1}^K E[P(x_0^k) - P(x_0^{k+1})]
\]
\[
+ \frac{3}{53} \sum_{k=1}^K \left( E[\text{Gap}_k(x_0^k, y_0^k)] - E[\text{Gap}_{k+1}(x_0^{k+1}, y_0^{k+1})] \right)
\]
\[
\leq 5\left( \frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda} \right) \ln(K + 1) + \frac{43}{53} E[\text{Gap}(x_0^1, y_0^1)],
\]
where the last inequality is due to the upper bounds the three terms $A$, $B$ and $C$ as follows. For the term $A$, we have
\[
A = \sum_{k=1}^K \frac{5\eta_k^2 M_1^2}{2} + \sum_{k=1}^K \frac{5\eta_y^2 M_2^2}{2} = \frac{10M_1^2}{\rho} \sum_{k=1}^K \frac{1}{k+1} + \frac{5M_2^2}{\lambda} \sum_{k=1}^K \frac{1}{k+1}
\]
\[
\leq 5\left( \frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda} \right) \ln(K + 1),
\]
where the second equality is due to the setting of $\eta_x^k = \frac{4}{\rho(k+1)}$ and $\eta_y^k = \frac{2}{\lambda(k+1)}$. The last inequality is due to $\sum_{k=1}^{K+1} \frac{1}{k} \leq \ln(K + 1) + 1$. 

12
For the term $B$, we have

$$B = \sum_{k=1}^{K} \mathbb{E}[P(x_0^k) - P(x_0^{k+1})] = \mathbb{E}[P(x_0^k) - P(x_0^{K+1})] = \mathbb{E}[f(x_0^k, \hat{y}(x_0^k)) - f(x_0^{K+1}, \hat{y}(x_0^{K+1}))]$$

$$\leq \mathbb{E}[f(x_0^k, \hat{y}(x_0^k)) - f(x_0^{K+1}, y_0^1)] \leq \mathbb{E}[f(x_0^k, \hat{y}(x_0^k)) - f(\hat{x}(y_0^1), y_0^1)] = \mathbb{E}[\text{Gap}(x_0, y_0^1)],$$

where the two inequalities are due to $f(x_0^{K+1}, \hat{y}(x_0^{K+1})) \geq f(x_0^{K+1}, y_0^1) \geq f(\hat{x}(y_0^1), y_0^1)$.

For the term $C$, we have

$$C = \sum_{k=1}^{K} \left( \mathbb{E}[\hat{\text{Gap}}_k(x_0^k, y_0^1) - \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{K+1})] \right)$$

$$= \mathbb{E}[\hat{\text{Gap}}_k(x_0^1, y_0^1) - \hat{\text{Gap}}_{K+1}(x_0^{K+1}, y_0^{K+1})] \leq \mathbb{E}[\hat{\text{Gap}}_k(x_0^1, y_0^1)]$$

$$= \mathbb{E}[f(x_0^k, \hat{y}(x_0^k))] + \frac{\gamma}{2}\|x_0^1 - x_0^k\|^2 - f(\hat{x}(y_0^1), y_0^1)] - \frac{\gamma}{2}\|\hat{x}(y_0^1) - x_0^1\|^2$$

$$\leq \mathbb{E}[f(x_0^k, \hat{y}(x_0^k)) - f(\hat{x}(y_0^1), y_0^1)] = \mathbb{E}[\text{Gap}(x_0, y_0^1)],$$

where the first inequality is due to $\hat{\text{Gap}}_{K+1}(x_0^{K+1}, y_0^{K+1}) \geq 0$. By plugging the above upper bounds of the three terms $A$, $B$ and $C$ into (11), we have (12).

Then by randomly sampling $\tau$ from $\{1, \ldots, K\}$, we have

$$\mathbb{E}[\|x_0^\tau - \hat{x}_\tau^\tau\|^2] \leq \frac{424}{\gamma K} \left( \frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda} \right) \ln(K + 1) + \frac{344}{5\gamma K} \mathbb{E}[\text{Gap}(x_0^1, y_0^1)].$$

Since $\mathbb{E}[	ext{Dist}(0, \partial P(\hat{x}_{\tau}^\tau))] \leq \frac{\gamma^2 1696\rho(\frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda})}{\epsilon^2} \ln\left(\frac{1696\rho(\frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda})}{\epsilon^2}\right)$, we could set

$$K = \max \left\{ \frac{1696\rho(\frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda})}{\epsilon^2} \ln\left(\frac{1696\rho(\frac{2M_1^2}{\rho} + \frac{M_2^2}{\lambda})}{\epsilon^2}\right), \frac{1376\rho \text{Gap}(x_0^1, y_0^1)}{5\epsilon^2} \right\},$$

which leads to $\gamma^2 \mathbb{E}[\|x_0^\tau - \hat{x}_\tau^\tau\|^2] \leq \epsilon^2$. Recall $T_k = \frac{106(k+1)}{3}$. To compute the total number of iterations, we have

$$T_{tot} = \sum_{k=1}^{K} T_k = \frac{106}{3} \sum_{k=1}^{K} (k + 1) = O(K^2) = O\left(\frac{1}{\epsilon^4}\right).$$

6. Conclusions

In this paper, we fill the gaps between stochastic min-max and minimization optimization problems. We propose Epoch-GDA algorithms for general SCSC and general WCSC problems, which do not impose any additional assumptions on the smoothness or the structure of the objective function. Our key lemma provides sharp analysis of Epoch-GDA for both problems. For SCSC min-max problems, to the best of our knowledge, our result is the first one to show that Epoch-GDA achieves the fast rate of $O(1/T)$ for the duality gap of general SCSC min-max problems. For WCSC min-max problems, our analysis allows us to derive the best complexity $\tilde{O}(1/\epsilon^4)$ of Epoch-GDA to reach a nearly $\epsilon$-stationary point, which does not require smoothness, large mini-batch sizes or other structural conditions.

Appendix A. Proof of Lemma 1

Proof

Let us first consider the first term in LHS of (2) as follows,
\[
\frac{\mu}{4} \|\hat{x}(y_1) - x_0\|^2 \\
\leq \frac{\mu}{2} \|\hat{x}(y_1) - x^*\|^2 + \frac{\mu}{2} \|x^* - x_0\|^2
\]
(a)
\[
\leq f(x^*, y_1) - f(\hat{x}(y_1), y_1) + f(x_0, y^*) - f(x^*, y^*)
\]
(b)
\[
\leq f(x^*, y^*) - f(\hat{x}(y_1), y_1) + f(x_0, y^*) - f(x^*, y^*)
\]
(c)
\[
\leq f(x_0, \hat{y}(x_0)) - f(\hat{x}(y_1), y_1),
\]
where inequality (a) is due to \(\mu\)-strong convexity of \(f(x, y_1)\) in \(x\) with fixed \(y_1\) (with optimality at \(\hat{x}(y_1)\)) and \(\mu\)-strong convexity of \(f(x, y^*)\) in \(x\) with fixed \(y^*\) (with optimality at \(x^*\)). Inequality (b) is due to \(f(x^*, y_1) \leq f(x^*, y^*)\). Inequality (c) is due to \(f(x_0, y^*) \leq f(x_0, \hat{y}(x_0))\).

In a similar way, for the second term, we have
\[
\frac{\lambda}{4} \|\hat{y}(x_1) - y_0\|^2 \\
\leq \frac{\lambda}{2} \|\hat{y}(x_1) - y^*\|^2 + \frac{\lambda}{2} \|y^* - y_0\|^2
\]
(a)
\[
\leq f(x_1, \hat{y}(x_1)) - f(x_1, y^*) + f(x^*, y^*) - f(x^*, y_0)
\]
(b)
\[
\leq f(x_1, \hat{y}(x_1)) - f(x^*, y^*) + f(x^*, y^*) - f(x^*, y_0)
\]
(c)
\[
\leq f(x_1, \hat{y}(x_1)) - f(\hat{x}(y_0), y_0),
\]
where inequality (a) is due to \(\lambda\)-strong concavity of \(f(x_1, y)\) in \(y\) with fixed \(x_1\) (optimality at \(\hat{y}(x_1)\)) and \(f(x^*, y)\) in \(y\) with fixed \(x^*\) (optimality at \(\hat{y}^*\)). Inequality (b) is due to \(f(x_1, y^*) \geq f(x^*, y^*)\). Inequality (c) is due to \(f(x^*, y_0) \geq f(\hat{x}(y_0), y_0)\).

Then, combining inequalities (13) and (14), we have
\[
\frac{\mu}{4} \|\hat{x}(y_1) - x_0\|^2 + \frac{\lambda}{4} \|\hat{y}(x_1) - y_0\|^2
\]
\[
\leq f(x_0, \hat{y}(x_0)) - f(\hat{x}(y_1), y_1) + f(x_1, \hat{y}(x_1)) - f(\hat{x}(y_0), y_0)
\]
\[
= \left( \max_{y' \in \Omega_2} f(x_0, y') - \min_{x' \in \Omega_1} f(x', y_0) \right) + \left( \max_{y' \in \Omega_2} f(x_1, y') - \min_{x' \in \Omega_1} f(x', y_1) \right).
\]

Appendix B. Proof of Lemma 2

Proof Before the proof, we first present the following two lemmas as follows.
Lemma 6 Let \( X_1, X_2, \ldots, X_T \) be independent random variables and \( \mathbb{E}_t[\exp(\frac{X_t^2}{\sigma_t^2})] \leq \exp(1) \) for any \( t \in \{1, \ldots, T\} \). Then we have with probability at least \( 1 - \delta \)
\[
\sum_{t=1}^{T} X_t \leq B^2(T + \log(1/\delta)).
\]

Lemma 7 (Lemma 2 of \cite{Lan et al., 2012}) Let \( X_1, \ldots, X_T \) be a martingale difference sequence, i.e., \( \mathbb{E}_t[X_t] = 0 \) for all \( t \). Suppose that for some values \( \sigma_t \), for \( t = 1, 2, \ldots, T \), we have \( \mathbb{E}_t[\exp(\frac{X_t^2}{\sigma_t^2})] \leq \exp(1) \). Then with probability at least \( 1 - \delta \), we have
\[
\sum_{t=1}^{T} X_t \leq \sqrt{3 \log(1/\delta)} \sum_{t=1}^{T} \sigma_t^2.
\]

For simplicity of presentation, we use the notations \( \Delta^t_x = \partial_x f(x_t, y_t; \xi_t), \Delta^t_y = \partial_y f(x_t, y_t; \xi_t), \partial_x^t = \partial_x f(x_t, y_t) \) and \( \partial_y^t = \partial_y f(x_t, y_t) \). To prove Lemma 2, we would leverage the following two update approaches:
\[
\begin{aligned}
& x_{t+1} = \arg\min_{x \in X \cap B(x_0, R)} x^\top \Delta^t_x + \frac{1}{2\eta_x} \|x - x_t\|^2 \\
& y_{t+1} = \arg\min_{y \in Y \cap B(y_0, R)} -y^\top \Delta^t_y + \frac{1}{2\eta_y} \|y - y_t\|^2
\end{aligned}
\]
\[
\begin{aligned}
& \tilde{x}_{t+1} = \arg\min_{x \in X \cap B(x_0, R)} x^\top \left( \partial^t_x - \Delta^t_x \right) + \frac{1}{2\eta_x} \|x - \tilde{x}_t\|^2 \\
& \tilde{y}_{t+1} = \arg\min_{y \in Y \cap B(y_0, R)} -y^\top \left( \partial^t_y - \Delta^t_y \right) + \frac{1}{2\eta_y} \|y - \tilde{y}_t\|^2,
\end{aligned}
\]
where \( x_0 = \tilde{x}_0 \) and \( y_0 = \tilde{y}_0 \). The first two updates are identical to Line 4 and Line 5 in Algorithm 1. This can be verified easily. Take the first one as example:
\[
x_{t+1} = \Pi_X(x_t - \eta_x \Delta^t_x) = \arg\min_{x \in X \cap B(x_0, R)} \|x - (x_t - \eta_x \Delta^t_x)\|^2
\]
\[
= \arg\min_{x \in X \cap B(x_0, R)} \frac{1}{2\eta_x}\|x - x_t\|^2 + x^\top \Delta^t_x.
\]
Let \( \psi(x) = x^\top u + \frac{1}{2\gamma} \|x - v\|^2 \) with \( x' = \arg\min_{x \in X'} \psi(x) \), which includes the four update approaches in (15) as special cases. By using the strong convexity of \( \psi(x) \) and the first order optimality condition \( \left( \partial \psi(x') \right)^\top (x - x') \geq 0 \), for any \( x \in X' \), we have
\[
\psi(x) - \psi(x') \geq \partial \psi(x')^\top (x - x') + \frac{1}{2\gamma} \|x - x'|^2 \geq \frac{1}{2\gamma} \|x - x'|^2,
\]
which implies
\[
0 \leq (x - x')^\top u + \frac{1}{2\gamma} \|x - v\|^2 - \frac{1}{2\gamma} \|x' - v\|^2 - \frac{1}{2\gamma} \|x - x'|^2
\]
\[
= (v - x')^\top u - (v - x)^\top u + \frac{1}{2\gamma} \|x - v\|^2 - \frac{1}{2\gamma} \|x' - v\|^2 - \frac{1}{2\gamma} \|x - x'|^2
\]
\[
= -\frac{1}{2\gamma} \|x' - v\|^2 + (v - x')^\top u + \frac{1}{2\gamma} \|x - v\|^2 - \frac{1}{2\gamma} \|x - x'|^2 - (v - x)^\top u
\]
\[
\leq \frac{\gamma}{2} \|u\|^2 + \frac{1}{2\gamma} \|x - v\|^2 - \frac{1}{2\gamma} \|x - x'|^2 - (v - x)^\top u.
\]
Then
\[
(v - x)^\top u \leq \frac{\gamma}{2} \|u\|^2 + \frac{1}{2\gamma} \|x - v\|^2 - \frac{1}{2\gamma} \|x - x'|^2.
\]
Applying the above result to the updates in (15), we have for any \( x \in X \cap B(x_0, R) \) and \( y \in Y \cap B(y_0, R) \),
\[
(x_t - x)^\top \Delta^t_x \leq \frac{1}{2\eta_x} ||x - x_t||^2 - \frac{1}{2\eta_x} ||x - x_{t+1}||^2 + \frac{\eta_x}{2} ||\Delta^t_x||^2
\]
\[
(y - y_t)^\top \Delta^t_y \leq \frac{1}{2\eta_y} ||y - y_t||^2 - \frac{1}{2\eta_y} ||y - y_{t+1}||^2 + \frac{\eta_y}{2} ||\Delta^t_y||^2
\]
\[
(\tilde{x}_t - x)^\top (\partial^t_x - \Delta^t_x) \leq \frac{1}{2\eta_x} ||x - \tilde{x}_t||^2 - \frac{1}{2\eta_x} ||x - \tilde{x}_{t+1}||^2 + \frac{\eta_x}{2} ||\partial^t_x - \Delta^t_x||^2
\]
\[
(\tilde{y}_t - y)^\top (\partial^t_y - \Delta^t_y) \leq \frac{1}{2\eta_y} ||y - \tilde{y}_t||^2 - \frac{1}{2\eta_y} ||y - \tilde{y}_{t+1}||^2 + \frac{\eta_y}{2} ||\partial^t_y - \Delta^t_y||^2.
\]
(17)

Adding the above four inequalities together, we have
\[
\text{LHS} = (x_t - x)^\top \Delta^t_x + (y - y_t)^\top \Delta^t_y + (\tilde{x}_t - x)^\top (\partial^t_x - \Delta^t_x) + (\tilde{y}_t - y)^\top (\partial^t_y - \Delta^t_y)
\]
\[
= (x_t - x)^\top \partial^t_x + (x_t - x)^\top (\Delta^t_x - \partial^t_x) + (y - y_t)^\top \partial^t_y + (y - y_t)^\top (\Delta^t_y - \partial^t_y)
\]
\[
+ (\tilde{x}_t - x)^\top (\partial^t_x - \Delta^t_x) + (\tilde{y}_t - y)^\top (\partial^t_y - \Delta^t_y)
\]
\[
= -(x_t - x)^\top \partial^t_x + (y - y_t)^\top \partial^t_y - (x_t - \tilde{x}_t)^\top (\partial^t_x - \Delta^t_x) - (\tilde{y}_t - y_t)^\top (\partial^t_y - \Delta^t_y)
\]
\[
(a) \geq - (f(x, y_t) - f(x_t, y_t)) + (f(x_t, y) - f(x_t, y_t)) - (x_t - \tilde{x}_t)^\top (\partial^t_x - \Delta^t_x) - (\tilde{y}_t - y_t)^\top (\partial^t_y - \Delta^t_y)
\]
\[
= f(x_t, y) - f(x_t, y_t) - (x_t - \tilde{x}_t)^\top (\partial^t_x - \Delta^t_x) - (\tilde{y}_t - y_t)^\top (\partial^t_y - \Delta^t_y)
\]
\[
\text{RHS} \leq \frac{1}{2\eta_x} \left\{ ||x - x_t||^2 - ||x - x_{t+1}||^2 + ||x - \tilde{x}_t||^2 - ||x - \tilde{x}_{t+1}||^2 \right\} + \frac{\eta_x}{2} \left\{ ||\Delta^t_x||^2 + ||\partial^t_x - \Delta^t_x||^2 \right\}
\]
\[
+ \frac{1}{2\eta_y} \left\{ ||y - y_t||^2 - ||y - y_{t+1}||^2 + ||y - \tilde{y}_t||^2 - ||y - \tilde{y}_{t+1}||^2 \right\} + \frac{\eta_y}{2} \left\{ ||\Delta^t_y||^2 + ||\partial^t_y - \Delta^t_y||^2 \right\}
\]
\[
\leq \frac{1}{2\eta_x} \left\{ ||x - x_t||^2 - ||x - x_{t+1}||^2 + ||x - \tilde{x}_t||^2 - ||x - \tilde{x}_{t+1}||^2 \right\} + \frac{\eta_x}{2} \left\{ 3||\Delta^t_x||^2 + 2||\partial^t_x||^2 \right\}
\]
\[
+ \frac{1}{2\eta_y} \left\{ ||y - y_t||^2 - ||y - y_{t+1}||^2 + ||y - \tilde{y}_t||^2 - ||y - \tilde{y}_{t+1}||^2 \right\} + \frac{\eta_y}{2} \left\{ 3||\Delta^t_y||^2 + 2||\partial^t_y||^2 \right\}
\]
(18)

where inequality (a) above is due to the convexity of \( f(x, y_t) \) in \( x \) and concavity of \( f(x_t, y) \) in \( y \). Inequality (b) is due to \((a + b)^2 \leq 2a^2 + 2b^2\).
Then we combine the LHS and RHS by summing up \( t = 0, ..., T - 1 \):

\[
\sum_{t=0}^{T-1} (f(x_t, y) - f(x, y)) \leq \frac{1}{2\eta_x} \left\{ \|x - x_0\|^2 - \|x - x_T\|^2 + \|x - x_0\|^2 - \|x - x_T\|^2 \right\} \\
\frac{1}{2\eta_y} \left\{ \|y - y_0\|^2 - \|y - y_T\|^2 + \|y - y_0\|^2 - \|y - y_T\|^2 \right\} \\
+ \frac{3\eta_x}{2} \sum_{t=1}^{T} \|\Delta_x^t\|^2 + \eta_x \sum_{t=1}^{T} \|\partial_x^t\|^2 \\
+ \frac{3\eta_y}{2} \sum_{t=1}^{T} \|\Delta_y^t\|^2 + \eta_y \sum_{t=1}^{T} \|\partial_y^t\|^2 \\
+ \sum_{t=0}^{T-1} \left( (x_t - \bar{x}_t)^\top (\partial_x^t - \Delta_x^t) + (y_t - \bar{y}_t)^\top (\partial_y^t - \Delta_y^t) \right). \tag{19}
\]

In the following, we show how to bound the above \( A \) to \( E \) terms. To bound the above term \( A \) in (19), we apply Lemma 6 as follows, which holds with probability \( 1 - \delta \),

\[
\sum_{t=1}^{T} \|\Delta_x^t\|^2 \leq B_1^2 (T + \log(1/\delta)). \tag{20}
\]

Similarly, term \( C \) in (19) can be bounded with probability \( 1 - \delta \) as follows

\[
\sum_{t=1}^{T} \|\Delta_y^t\|^2 \leq B_2^2 (T + \log(1/\delta)). \tag{21}
\]

To bound term \( B \) of (19), which contains only the full subgradients \( \partial_x^t \), we have

\[
\|\partial_x^t\|^2 = \|E[\Delta_x^t]\|^2 \leq E[\|\Delta_x^t\|^2] \leq B_2^2,
\]

where the first inequality is due to Jensen’s inequality and the second inequality is due to

\[
\exp(E[\|\Delta_x^t\|^2]) \leq \exp(E[\|\Delta_x^t\|^2]) \leq \exp(1) \Rightarrow E[\|\Delta_x^t\|^2] \leq 1 \Rightarrow E[\|\Delta_x^t\|^2] \leq B_2^2.
\]

Therefore, we have

\[
\sum_{t=1}^{T} \|\partial_x^t\|^2 \leq TB_1^2. \tag{22}
\]

Similarly, for term \( D \) in (19), we have

\[
\sum_{t=1}^{T} \|\partial_y^t\|^2 \leq TB_2^2. \tag{23}
\]

To bound term \( E \) of (19), let \( U_t = (x_t - \bar{x}_t)^\top (\partial_x^t - \Delta_x^t) \) and \( V_t = (y_t - \bar{y}_t)^\top (\partial_y^t - \Delta_y^t) \) for \( t \in \{0, ..., T - 1\} \), which are Martingale difference sequences. We thus would like to use Lemma 7 to handle these terms. To this end, we can first upper bound \( |U_t| \) and \( |V_t| \) as
follows
\[ |U_t| = |(x_t - \bar{x}_t) \cdot (\partial_x^2 - \Delta_x^2)| \leq \|x_t - x_0 + x_0 - \bar{x}_t\| \cdot \|\partial_x^2 - \Delta_x^2\| \leq 2R(\|\partial_x^2\| + \|\Delta_x^2\|) \leq 2R(B_1 + \|\Delta_x^2\|), \]
\[ |V_t| = |(y_t - \bar{y}_t) \cdot (\partial_y^2 - \Delta_y^2)| \leq \|(y_t - y_0 + y_0 - \bar{y}_t\| \cdot \|\partial_y^2 - \Delta_y^2\| \leq 2R(\|\partial_y^2\| + \|\Delta_y^2\|) \leq 2R(B_2 + \|\Delta_y^2\|). \]
Then the above two inequalities implies that
\[
E_t\exp\left(\frac{U_t^2}{16B_1^2R^2}\right) \leq E_t\exp\left(\frac{2R(B_1 + \|\Delta_x^2\|)^2}{16B_1^2R^2}\right) \leq E_t\exp\left(\frac{4R^2(2B_1^2 + 2\|\Delta_x^2\|^2)}{16B_1^2R^2}\right)
\]
\[
= E_t\exp\left(\frac{B_1^2 + \|\Delta_x^2\|^2}{2B_1^2}\right) = E_t\exp\left(\frac{1}{2} + \frac{\|\Delta_x^2\|^2}{B_1^2}\right)
\]
\[
= \exp\left(\frac{1}{2}\right) \cdot E_t\left[\sqrt{\exp\left(\frac{\|\Delta_x^2\|^2}{B_1^2}\right)}\right] \leq \exp\left(\frac{1}{2}\right) \cdot \sqrt{E_t\exp\left(\frac{\|\Delta_x^2\|^2}{B_1^2}\right)}
\]
\[
\leq \exp\left(\frac{1}{2}\right) \sqrt{\exp(1)} = \exp(1), \tag{24}\]
where inequality (a) is due to \((a + b)^2 \leq 2a^2 + 2b^2\), inequality (b) is due to the concavity of \(\sqrt{\cdot}\) and Jensen’s inequality. Inequality (c) is due to the assumption. In a similar way, we have
\[
E_t\exp\left(\frac{V_t^2}{16B_2^2R^2}\right) \leq \exp(1). \tag{25}\]
Next, applying Lemma 7 with (24) and (25), we have with probability at least 1 - \(\tilde{\delta}\)
\[
\sum_{t=0}^{T-1} U_t \leq 4B_1 R \sqrt{3\log(1/\tilde{\delta})T},
\]
\[
\sum_{t=0}^{T-1} V_t \leq 4B_2 R \sqrt{3\log(1/\tilde{\delta})T}. \tag{26}\]
For LHS of (19), by Jensen’s inequality, we have
\[
\sum_{t=0}^{T-1} (f(x_t, y) - f(x, y)) \geq T(f(\bar{x}, y) - f(x, \bar{y})) \tag{27}\]
where \(\bar{x} = \frac{1}{T} \sum_{t=0}^{T-1} x_t\) and \(\bar{y} = \frac{1}{T} \sum_{t=0}^{T-1} y_t\).
Suppose \(T \geq 1\). By plugging (27), (20), (21), (22), (23) and (26) back into (19), with probability at least 1 - \(\tilde{\delta}\), we have
\[
\frac{f(\bar{x}, y) - f(x, \bar{y})}{\sqrt{T}} \leq \frac{\|x - x_0\|^2}{\eta_x T} + \frac{\|y - y_0\|^2}{\eta_y T} + \frac{\eta_x B_1^2}{2}(5 + 3\log(1/\tilde{\delta})) + \frac{\eta_x B_1^2}{2}(5 + 3\log(1/\tilde{\delta}))
\]
\[
+ \frac{4(B_1 + B_2) R \sqrt{3\log(1/\tilde{\delta})}}{\sqrt{T}} \tag{28}\]
Appendix C. Proof of Lemma 6

Proof First, we start from
\[
\mathbb{E}[\exp\left(\frac{\sum_{t=1}^{T} X_t}{B^2}\right)]=\mathbb{E}[\mathbb{E}_T[\exp\left(\frac{\sum_{t=1}^{T-1} X_t + X_T}{B^2}\right)]]
\]
\[
=\mathbb{E}[\exp\left(\frac{\sum_{t=1}^{T-1} X_t}{B^2}\right) \cdot \mathbb{E}_T[\exp\left(\frac{X_T}{B^2}\right)]]
\]
\[
\leq \mathbb{E}[\exp\left(\frac{\sum_{t=1}^{T-1} X_t}{B^2}\right) \cdot \exp(1)]
\]
\[
\leq \mathbb{E}[\exp\left(\frac{\sum_{t=1}^{T-2} X_t}{B^2}\right) \cdot \exp(2)]
\]
\[
\leq \exp(T),
\]
where the first inequality is due to the assumption.

Markov inequality indicates that
\[
P(X \geq a) \leq \frac{\mathbb{E}[X]}{a}
\]
for a random variable \(X\), which, by additionally introducing \(\tilde{\delta}\), leads to
\[
P\left(\exp\left(\frac{\sum_{t=1}^{T} X_t}{B^2}\right) \geq \frac{\mathbb{E}[\exp\left(\frac{\sum_{t=1}^{T} X_t}{B^2}\right)]}{\tilde{\delta}}\right) \leq \tilde{\delta}.
\]
Therefore, with probability at least \(1 - \tilde{\delta}\), we have
\[
\exp\left(\frac{\sum_{t=1}^{T} X_t}{B^2}\right) \leq \frac{\mathbb{E}[\exp\left(\frac{\sum_{t=1}^{T} X_t}{B^2}\right)]}{\tilde{\delta}} \leq \frac{\exp(T)}{\delta}
\]
\[
\Rightarrow \frac{\sum_{t=1}^{T} X_t}{B^2} \leq \log\left(\frac{\exp(T)}{\delta}\right) = \log(\exp(T)) + \log(1/\delta) = T + \log(1/\delta)
\]
\[
\Rightarrow \sum_{t=1}^{T} X_t \leq B^2(T + \log(1/\delta)).
\]

Appendix D. Proof of Lemma 3

Proof Here we consider the following problem
\[
\min_{x \in X \cap B(x_0,R)} \max_{y \in Y \cap B(y_0,R)} f(x, y)
\]
with two solutions \((x_0, y_0)\) and \((\bar{x}, \bar{y})\).

By (1) of Lemma 1, we have
\[
\frac{\mu}{4} \|\bar{x} - x_0\|^2 + \frac{\lambda}{4} \|\bar{y} - y_0\|^2 \leq \max_{y' \in Y \cap B(y_0,R)} f(x_0, y') - \min_{x \in X \cap B(x_0,R)} f(x', y_0)
\]
\[
\quad \quad \quad \underbrace{\max_{y' \in Y \cap B(y_0,R)} f(x, y') - \min_{x \in X \cap B(x_0,R)} f(x', y)}_{:= A}
\]
\[
\quad \quad \quad \underbrace{+ \max_{y' \in Y \cap B(y_0,R)} f(x, y') - \min_{x \in X \cap B(x_0,R)} f(x', y)}_{:= B}.
\]

(29)
We can bound the above term $A$ as follows

$$\max_{y' \in Y \cap B(y_0, R)} f(x_0, y') - \min_{x' \in X \cap B(x_0, R)} f(x', y_0) \leq \max_{y' \in Y} f(x_0, y') - \min_{x \in X} f(x', y_0) \leq \frac{\min\{\mu, \lambda\} R^2}{8},$$  \hspace{1cm} (30)

where the last inequality is due to the setting of $R$.

Recall the definitions

$$\hat{x}_R(\bar{y}) = \arg\min_{x' \in x \cap B(x_0, R)} f(x', \bar{y}),$$

$$\hat{y}_R(\bar{x}) = \arg\max_{y' \in y \cap B(y_0, R)} f(\bar{x}, y').$$

To Bound term $B$ in (29), we apply Lemma 2 as follows

$$\max_{y' \in Y \cap B(y_0, R)} f(\hat{x}_R(\bar{y}), y') - \min_{x' \in x \cap B(x_0, R)} f(\hat{x}_R(\bar{y}), y) \leq \frac{\|\hat{x}_R(\bar{y}) - x_0\|}{\eta_x T} + \frac{\|\hat{y}_R(\hat{x}) - y_0\|}{\eta_y T} + \frac{\eta_x B_1^2}{2} \left(5 + 3 \log(1/\hat{\delta})\right) + \frac{\eta_y B_2^2}{2} \left(5 + 3 \log(1/\hat{\delta})\right) + \frac{4(B_1 + B_2) R \sqrt{2 \log(1/\hat{\delta})}}{\sqrt{T}}$$

$$\leq \frac{R^2}{\eta_x T} + \frac{R^2}{\eta_y T} + \frac{\eta_x B_1^2}{2} \left(5 + 3 \log(1/\hat{\delta})\right) + \frac{\eta_y B_2^2}{2} \left(5 + 3 \log(1/\hat{\delta})\right) + \frac{4(B_1 + B_2) R \sqrt{2 \log(1/\hat{\delta})}}{\sqrt{T}}$$

$$\leq \frac{\min\{\mu, \lambda\} R^2}{16},$$  \hspace{1cm} (31)

where the last inequality holds with probability at least $1 - \hat{\delta}$ with the setting of $\eta_x$, $\eta_y$ and $T$ as follows

$$\eta_x = \frac{\min\{\mu, \lambda\} R^2}{40(5 + 3 \log(1/\hat{\delta}))) B_1^2}, \eta_y = \frac{\min\{\mu, \lambda\} R^2}{40(5 + 3 \log(1/\hat{\delta}))) B_2^2}$$

$$T \geq \max\left\{320^2(B_1 + B_1)^2 3 \log(1/\hat{\delta}), 3200(5 + 3 \log(1/\hat{\delta})) \max\{B_1^2, B_2^2\}\right\} \frac{\min\{\mu, \lambda\} R^2}{\max\{\mu, \lambda\}^2 R^2}. \hspace{1cm} (32)$$

Finally, we use (30) and (31) to bound term $A$ and term $B$ in (29) as follows

$$\frac{\mu}{4} \|\hat{x}_R(\bar{y}) - x_0\|^2 + \frac{\lambda}{4} \|\hat{y}_R(\hat{x}) - y_0\|^2 \leq \frac{\min\{\mu, \lambda\} R^2}{8} + \frac{\min\{\mu, \lambda\} R^2}{16} = \frac{3 \min\{\mu, \lambda\} R^2}{16} < \frac{\min\{\mu, \lambda\} R^2}{4}.$$

It implies

$$\|\hat{x}_R(\bar{y}) - x_0\| < R,$$

$$\|\hat{y}_R(\hat{x}) - y_0\| < R,$$

which shows $\hat{x}_R(\bar{y})$ and $\hat{y}_R(\hat{x})$ are interior points of $B(x_0, R)$ and $B(y_0, R)$, respectively, so that $\hat{x}_R(\bar{y}) = \hat{x}(\bar{y})$ and $\hat{y}_R(\hat{x}) = \hat{y}(\hat{x})$.
Appendix E. Proof of Theorem 1

Proof Let

\[ T_1 = \max \left\{ \frac{320^2(B_1 + B_2)^23\log(1/\tilde{\delta}), 3200(3\log(1/\tilde{\delta}) + 2)\max\{B_1^2, B_2^2\}}{\min\{\mu, \lambda\}^2R_1^2} \right\}, \]

where \( \text{Gap}(x_0, y_0) = \max_{y \in Y} f(x_0, y) - \min_{x \in X} f(x, y_0) \leq \epsilon_0 \) and \( R_1 \geq 2\sqrt{\frac{2\epsilon_0}{\min\{\mu, \lambda\}}} \).

Given \( T_{k+1} = 2T_k \) in Algorithm 1 and \( K = \lceil \log(\frac{\gamma_0}{\epsilon}) \rceil \), the total number of iterations can be computed by

\[ T_{tot} = \sum_{k=1}^{K} T_k = T_1 \sum_{k=1}^{K} 2^{k-1} = T_1 (2^K - 1) \leq T_1 2^{\lceil \log(\frac{\gamma_0}{\epsilon}) \rceil} \leq T_1 \frac{2\epsilon_0}{\epsilon}, \]

\[ \leq \max \left\{ \frac{320^2(B_1 + B_2)^23\log(1/\tilde{\delta}), 3200(3\log(1/\tilde{\delta}) + 2)\max\{B_1^2, B_2^2\}}{\min\{\mu, \lambda\}^2R_1^2} \right\} \cdot \frac{2\epsilon_0}{\epsilon}, \]

\[ \leq \frac{\max\{320^2(B_1 + B_2)^23\log(1/\tilde{\delta}), 3200(3\log(1/\tilde{\delta}) + 2)\max\{B_1^2, B_2^2\}\}}{8 \min\{\mu, \lambda\} \epsilon_0} \cdot \frac{2\epsilon_0}{\epsilon}, \]

\[ \leq \frac{\max\{320^2(B_1 + B_2)^23\log(1/\tilde{\delta}), 3200(3\log(1/\tilde{\delta}) + 2)\max\{B_1^2, B_2^2\}\}}{4 \min\{\mu, \lambda\} \epsilon} \cdot \frac{2\epsilon_0}{\epsilon}. \]

Appendix F. Proof of Lemma 4

Proof In this proof, we focus on the analysis of one inner loop and thus omit the index of \( k \) for simpler presentation. Let \( \Delta^t_x = \partial_x f(x_t, y_t; \xi_t) \), \( \Delta^t_y = \partial_y f(x_t, y_t; \xi_t) \) and \( \Delta^t_y = \partial_y f(x_t, y_t) \). Denote \( \hat{f}(x, y) = f(x, y) + \frac{\gamma}{2}\|x - x_0\|^2 \).

Let \( \psi^t_x(x) = x^\top \Delta^t_x + \frac{1}{2\eta_x} \|x - x_t\|^2 + \frac{\gamma}{2} \|x - x_0\|^2 \) and \( \psi^t_y(y) = -y^\top \Delta^t_y + \frac{1}{2\eta_y} \|y - y_t\|^2 \).

According to the update of \( x_{t+1} \) and \( y_{t+1} \), we have \( x_{t+1} = \arg\min_{x \in X} \psi^t_x(x) \) and \( y_{t+1} = \arg\max_{y \in Y} \psi^t_y(y) \). It is easy to verify that \( \psi^t_x \) and \( \psi^t_y \) are strongly convex in \( x \) and \( y \), respectively.
By \((\frac{1}{\eta_x} + \gamma)\)-strong convexity of \(\psi^t_y(x)\) and the optimality condition at \(x_{t+1}\), we have

\[
\left(\frac{1}{2\eta_x} + \frac{\gamma}{2}\right)\|x - x_{t+1}\|^2 \leq \psi^t_y(x) - \psi^t_y(x_{t+1})
\]

\[
= x^\top \Delta^t_x + \frac{1}{2\eta_x}\|x - x_t\|^2 + \frac{\gamma}{2}\|x - x_0\|^2 - \left(x^\top_{t+1}\Delta^t_x + \frac{1}{2\eta_x}\|x_{t+1} - x_t\|^2 + \frac{\gamma}{2}\|x_{t+1} - x_0\|^2\right)
\]

\[
= \left(x - x_t\right)^\top \partial^t_x + \left(x - x_{t+1}\right)^\top \partial^t_x + \left(x - x_{t+1}\right)^\top (\Delta^t_x - \partial^t_x)
\]

\[
+ \frac{1}{2\eta_x}\|x - x_t\|^2 + \frac{\gamma}{2}\|x - x_0\|^2 - \frac{1}{2\eta_x}\|x_{t+1} - x_t\|^2 - \frac{\gamma}{2}\|x_{t+1} - x_0\|^2
\]

\[
\leq f(x, y) - f(x_t, y_t) + \frac{\gamma}{2}\|x - x_0\|^2 - \frac{\gamma}{2}\|x_t - x_0\|^2 + \frac{\gamma}{2}\left(\|x_t - x_0\|^2 - \|x_{t+1} - x_0\|^2\right)
\]

\[
+ \left(\frac{1}{2\eta_x} + \frac{\rho}{2}\right)\|x - x_t\|^2 + \left(x - x_t\right)^\top (\Delta^t_x - \partial^t_x) + \left(x - x_{t+1}\right)^\top \Delta^t_x - \frac{1}{2\eta_x}\|x_{t+1} - x_t\|^2
\]

\[
\leq \hat{f(x, y)} - \hat{f(x_t, y_t)} + \frac{\gamma}{2}\left(\|x - x_0\|^2 - \|x_t - x_0\|^2\right)
\]

\[
+ \left(\frac{1}{2\eta_y} + \frac{\rho}{2}\right)\|y - y_t\|^2 + \left(y - y_t\right)^\top (\Delta^t_y - \partial^t_y) + \left(y - y_{t+1}\right)^\top \Delta^t_y - \frac{1}{2\eta_y}\|y_{t+1} - y_t\|^2
\]

where inequality \((a)\) is due to \(\rho\)-weakly convexity of \(f\) in \(x\). Inequality \((b)\) is due to Young’s inequality, i.e., \((x_{t+1} - x_t)^\top \Delta^t_x - \frac{1}{2\eta_x}\|x_{t+1} - x_t\|^2 \leq \frac{\eta_x}{2} \|\Delta^t_x\|^2\).

Similarly, due to the \(\frac{1}{\eta_y}\)-strong convexity of \(\psi^t_y(y)\) in \(y\) and the optimality condition of \(y_{t+1}\), we have

\[
\frac{1}{2\eta_y}\|y - y_{t+1}\|^2 \leq \psi^t_y(y) - \psi^t_y(y_{t+1})
\]

\[
= - y^\top \Delta^t_y + \frac{1}{2\eta_y}\|y - y_t\|^2 - \left(- y^\top_{t+1}\Delta^t_y + \frac{1}{2\eta_y}\|y_{t+1} - y_t\|^2\right)
\]

\[
= \left(y_t - y\right)^\top \partial^t_y + \left(y_{t+1} - y_t\right)^\top \partial^t_y + \left(y_{t+1} - y\right)^\top (\Delta^t_y - \partial^t_y)
\]

\[
+ \frac{1}{2\eta_y}\|y - y_t\|^2 - \frac{1}{2\eta_y}\|y_{t+1} - y_t\|^2
\]

\[
\leq f(x_t, y_t) - f(x, y) + \left(y_t - y\right)^\top (\Delta^t_y - \partial^t_y) + \left(y_{t+1} - y\right)^\top (\Delta^t_y - \partial^t_y)
\]

\[
+ \frac{1}{2\eta_y}\|y - y_t\|^2 - \frac{1}{2\eta_y}\|y_{t+1} - y_t\|^2
\]

\[
\leq \hat{f(x_t, y_t)} - \hat{f(x, y)} + \left(y_t - y\right)^\top (\Delta^t_y - \partial^t_y) + \left(y_{t+1} - y\right)^\top (\Delta^t_y - \partial^t_y) + \frac{1}{2\eta_y}\|y - y_t\|^2 + \frac{\eta_y}{2} \|\Delta^t_y\|^2,
\]

where inequality \((a)\) is due to concavity of \(f\) in \(y\). Inequality \((b)\) is due to Young’s inequality, i.e., \((y_{t+1} - y_t)^\top \Delta^t_y - \frac{1}{2\eta_y}\|y_{t+1} - y_t\|^2 \leq \frac{\eta_y}{2} \|\Delta^t_y\|^2\).

Combining \((33)\) and \((34)\), we have

\[
\hat{f(x_t, y)} - \hat{f(x, y)} \leq \frac{\eta_y}{2} \|\Delta^t_y\|^2 + \frac{\eta_y}{2} \|\Delta^t_y\|^2
\]

\[
+ (x - x_t)^\top (\Delta^t_x - \partial^t_x) + (y_t - y)^\top (\Delta^t_y - \partial^t_y) + \frac{\gamma}{2}\left(\|x_t - x_0\|^2 - \|x_{t+1} - x_0\|^2\right)
\]

\[
+ \left(\frac{1}{2\eta_x} + \frac{\rho}{2}\right)\|x - x_t\|^2 - \left(\frac{1}{2\eta_y} + \frac{\gamma}{2}\right)\|y - y_t\|^2 - \frac{1}{2\eta_y}\|y - y_{t+1}\|^2\).
\]
Now we do not take expectation, since we aim to eliminate the randomness of $x$ and $y$ in $(x - x_t)$ and $(y_t - y)$, respectively. To achieve this, we use the following updates

$$
\tilde{x}_{t+1} = \arg\min_{x \in X} x^\top (\partial^t_x - \Delta^t_x) + \frac{1}{2 \eta_x} \|x - \tilde{x}_t\|^2
$$

$$
\tilde{y}_{t+1} = \arg\min_{y \in Y} -y^\top (\partial^t_y - \Delta^t_y) + \frac{1}{2 \eta_y} \|y - \tilde{y}_t\|^2,
$$

where $\tilde{x}_0 = x_0$ and $\tilde{y}_0 = y_0$.

Using similar analysis as the beginning, we have

$$
\frac{1}{2 \eta_x} \|x - \tilde{x}_{t+1}\|^2 \leq x^\top (\partial^t_x - \Delta^t_x) + \frac{1}{2 \eta_x} \|x - \tilde{x}_t\|^2 - \left( \tilde{x}_{t+1}^\top (\partial^t_x - \Delta^t_x) + \frac{1}{2 \eta_x} \|	ilde{x}_{t+1} - \tilde{x}_t\|^2 \right)
$$

$$
= (\tilde{x}_t - x)^\top (\Delta^t_x - \partial^t_x) + \frac{1}{2 \eta_x} \|x - \tilde{x}_t\|^2 - (\tilde{x}_{t+1}^\top (\partial^t_x - \Delta^t_x) + \frac{1}{2 \eta_x} \|	ilde{x}_{t+1} - \tilde{x}_t\|^2)
$$

$$
\leq (\tilde{x}_t - x)^\top (\Delta^t_x - \partial^t_x) + \frac{1}{2 \eta_x} \|x - \tilde{x}_t\|^2 - \frac{\eta_x}{2} \|\partial^t_x - \Delta^t_x\|^2
$$

$$
\leq (\tilde{x}_t - x)^\top (\Delta^t_x - \partial^t_x) + \frac{1}{2 \eta_x} \|x - \tilde{x}_t\|^2 + \eta_x \|\partial^t_x\|^2 + \eta_x \|\Delta^t_x\|^2.
$$

We could also derive the similar result for $y$ as follows

$$
\frac{1}{2 \eta_y} \|y - \tilde{y}_{t+1}\|^2 \leq -y^\top (\partial^t_y - \Delta^t_y) + \frac{1}{2 \eta_y} \|y - \tilde{y}_t\|^2 - \left( -\tilde{y}_{t+1}^\top (\partial^t_y - \Delta^t_y) + \frac{1}{2 \eta_y} \|\tilde{y}_{t+1} - \tilde{y}_t\|^2 \right)
$$

$$
= (y - \tilde{y}_t)^\top (\Delta^t_y - \partial^t_y) + \frac{1}{2 \eta_y} \|y - \tilde{y}_t\|^2 - (\tilde{y}_{t+1}^\top (\partial^t_y - \Delta^t_y) - \frac{1}{2 \eta_y} \|	ilde{y}_{t+1} - \tilde{y}_t\|^2)
$$

$$
\leq (y - \tilde{y}_t)^\top (\Delta^t_y - \partial^t_y) + \frac{1}{2 \eta_y} \|y - \tilde{y}_t\|^2 + \frac{\eta_y}{2} \|\partial^t_y - \Delta^t_y\|^2
$$

$$
\leq (y - \tilde{y}_t)^\top (\Delta^t_y - \partial^t_y) + \frac{1}{2 \eta_y} \|y - \tilde{y}_t\|^2 + \eta_y \|\partial^t_y\|^2 + \eta_y \|\Delta^t_y\|^2.
$$

Summing the above two inequalities, we have

$$
0 \leq \frac{1}{2 \eta_x} \left( \|x - \tilde{x}_t\|^2 - \|x - \tilde{x}_{t+1}\|^2 \right) + (\tilde{x}_t - x)^\top (\Delta^t_x - \partial^t_x) + \eta_x \|\partial^t_x\|^2 + \eta_x \|\Delta^t_x\|^2
$$

$$
+ \frac{1}{2 \eta_y} \left( \|y - \tilde{y}_t\|^2 - \|y - \tilde{y}_{t+1}\|^2 \right) + (y - \tilde{y}_t)^\top (\Delta^t_y - \partial^t_y) + \eta_y \|\partial^t_y\|^2 + \eta_y \|\Delta^t_y\|^2 \tag{36}
$$
Combining (35) and (36), we have
\[
\hat{f}(x_t, y) - \hat{f}(x, y_t) \leq \frac{\eta_x}{2} \| \Delta^t_x \|^2 + \frac{\eta_y}{2} \| \Delta^t_y \|^2 \\
+ (x - x_t) \top (\Delta^t_x - \partial_x^t) + (y_t - y) \top (\Delta^t_y - \partial_y^t) + \frac{\gamma}{2} \left( \| x_t - x_0 \|^2 - \| x_{t+1} - x_0 \|^2 \right) \\
+ \left( \frac{1}{2\eta_x} + \frac{\rho}{2} \right) \| x - x_t \|^2 - \left( \frac{1}{2\eta_x} + \frac{\gamma}{2} \right) \| x - x_{t+1} \|^2 + \frac{1}{2\eta_y} \left( \| y - y_t \|^2 - \| y - y_{t+1} \|^2 \right) \\
+ \frac{1}{2\eta_x} \left( \| x - \bar{x}_t \|^2 - \| x - \bar{x}_{t+1} \|^2 \right) + (\bar{x}_t - x) \top (\Delta^t_x - \partial_x^t) + \eta_x \| \partial_x^t \|^2 + \eta_x \| \Delta^t_x \|^2 \\
+ \frac{1}{2\eta_y} \left( \| y - \bar{y}_t \|^2 - \| y - \bar{y}_{t+1} \|^2 \right) + (y - \bar{y}_t) \top (\Delta^t_y - \partial_y^t) + \eta_y \| \partial_y^t \|^2 + \eta_y \| \Delta^t_y \|^2 \\
= \frac{3\eta_x}{2} \| \Delta^t_x \|^2 + \eta_x \| \partial_x^t \|^2 + \frac{3\eta_y}{2} \| \Delta^t_y \|^2 + \eta_y \| \partial_y^t \|^2 \\
+ (\bar{x}_t - x_t) \top (\Delta^t_x - \partial_x^t) + (y_t - \bar{y}_t) \top (\Delta^t_y - \partial_y^t) + \frac{\gamma}{2} \left( \| x_t - x_0 \|^2 - \| x_{t+1} - x_0 \|^2 \right) \\
+ \left( \frac{1}{2\eta_x} + \frac{\rho}{2} \right) \| x - x_t \|^2 - \left( \frac{1}{2\eta_x} + \frac{\gamma}{2} \right) \| x - x_{t+1} \|^2 + \frac{1}{2\eta_y} \left( \| y - y_t \|^2 - \| y - y_{t+1} \|^2 \right) \\
+ \frac{1}{2\eta_x} \left( \| x - \bar{x}_t \|^2 - \| x - \bar{x}_{t+1} \|^2 \right) + \frac{1}{2\eta_y} \left( \| y - \bar{y}_t \|^2 - \| y - \bar{y}_{t+1} \|^2 \right)
\]

Summing the above inequality from $t = 0$ to $T - 1$ and using Jensen's inequality, we have
\[
T \left( \hat{f}(\bar{x}, y) - \hat{f}(x, \bar{y}) \right) \leq \sum_{t=0}^{T-1} \left( \hat{f}(x_t, y) - \hat{f}(x, y_t) \right) \\
\leq \frac{\eta_x}{2} \sum_{t=0}^{T-1} (3\| \Delta^t_x \|^2 + 2\| \partial_x^t \|^2) + \frac{\eta_y}{2} \sum_{t=0}^{T-1} (3\| \Delta^t_y \|^2 + 2\| \partial_y^t \|^2) \\
+ \sum_{t=0}^{T-1} (\bar{x}_t - x_t) \top (\Delta^t_x - \partial_x^t) + \sum_{t=0}^{T-1} (y_t - \bar{y}_t) \top (\Delta^t_y - \partial_y^t) + \frac{\gamma}{2} \left( \| x_0 - x_0 \|^2 - \| x_T - x_0 \|^2 \right) \\
+ \left( \frac{1}{2\eta_x} + \frac{\rho}{2} \right) \| x - x_0 \|^2 - \left( \frac{1}{2\eta_x} + \frac{\gamma}{2} \right) \| x - x_T \|^2 + \frac{1}{2\eta_y} \left( \| y - y_0 \|^2 - \| y - y_T \|^2 \right) \\
+ \frac{1}{2\eta_x} \left( \| x - x_0 \|^2 - \| x - \bar{x}_T \|^2 \right) + \frac{1}{2\eta_y} \left( \| y - y_0 \|^2 - \| y - \bar{y}_T \|^2 \right)
\]

where $\bar{x} = \frac{1}{T} \sum_{t=0}^{T-1} x_t$ and $\bar{y} = \frac{1}{T} \sum_{t=0}^{T-1} y_t$. 

---

Epoch Stochastic Gradient Descent Ascent Methods for Min-Max Optimization
Plugging in \( x = \hat{x}(\bar{y}) \) and \( y = \bar{y}(\bar{x}) \), we have

\[
\hat{\text{Gap}}(\bar{x}, \bar{y}) = \hat{f}(\bar{x}, \hat{y}(\bar{x})) - \hat{f}(\hat{x}(\bar{y}), \bar{y}) \leq \frac{1}{T} \sum_{t=0}^{T-1} \left( \hat{f}(x_t, \hat{y}(\bar{x})) - \hat{f}(\hat{x}(\bar{y}), y_t) \right)
\]

\[
\leq \frac{\eta_x}{2T} \sum_{t=0}^{T-1} \left( 3\|\Delta^t_x\|^2 + \|\partial^t_x\|^2 \right) + \frac{\eta_y}{2T} \sum_{t=0}^{T-1} \left( 3\|\Delta^t_y\|^2 + \|\partial^t_y\|^2 \right)
\]

\[
+ \frac{1}{T} \sum_{t=0}^{T} (\hat{x}_t - x_t)^\top (\Delta^t_x - \partial^t_x) + \frac{1}{T} \sum_{t=0}^{T} (y_t - \bar{y}_t)^\top (\Delta^t_y - \partial^t_y)
\]

\[
+ \frac{1}{T} \left( \frac{1}{\eta_x} + \frac{\rho}{2} \right) \|\hat{x}(\bar{y}) - x_0\|^2 + \frac{1}{\eta_y T} \|\hat{y}(\bar{x}) - y_0\|^2
\]

Taking expectation over both sides and recalling that \( E[\|\partial_x f(x, y; \xi)\|^2] \leq M_1^2 \) and \( E[\|\partial_y f(x, y; \xi)\|^2] \leq M_2^2 \), we have

\[
E[\hat{\text{Gap}}(\bar{x}, \bar{y})] = E[\hat{f}(\bar{x}, \hat{y}(\bar{x})) - \hat{f}(\hat{x}(\bar{y}), \bar{y})] \leq \frac{1}{T} \sum_{t=0}^{T-1} E[\hat{f}(x_t, \hat{y}(\bar{x})) - \hat{f}(\hat{x}(\bar{y}), y_t)]
\]

\[
\leq \frac{5\eta_x M_1^2}{2} + \frac{5\eta_y M_2^2}{2} + \frac{1}{T} \left( \frac{1}{\eta_x} + \frac{\rho}{2} \right) E[\|\hat{x}(\bar{y}) - x_0\|^2] + \frac{1}{\eta_y T} E[\|\hat{y}(\bar{x}) - y_0\|^2].
\]

\[\square\]

**Appendix G. Proof of Lemma 5**

Before proving Lemma 5, we first state the following lemma, whose proof is in the next section.

**Lemma 8** \( \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \) could be lower bounded by the following inequalities

1. \( \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \geq (1 - \frac{\gamma}{\rho}(\frac{1}{\alpha} - 1)) \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{\gamma}{2}(1 - \frac{1}{1 - \alpha})\|x_0^{k+1} - x_0^k\|^2 \),

2. \( \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \geq P(x_0^{k+1}) - P(x_0^k) + \frac{\gamma}{2}\|\bar{x}_k - x_0^k\|^2 \), where \( P(x) = \max_{y \in Y} f(x, y) \),

3. \( \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \geq \frac{\rho(1 - \beta)}{2(\beta - 1)}\|x_0^k - \bar{x}_k\|^2 - \frac{\rho}{2(\beta - 1)}\|\bar{x}_k - x_0^k\|^2 \),

(37)

where \( 0 < \alpha \leq 1 \) and \( 0 < \beta \leq 1 \).
Proof (of Lemma 5)
\[
\begin{align*}
\hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \\
= & \frac{1}{10} \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) + \frac{4}{5} \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) + \frac{1}{10} \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \\
\geq & \frac{1}{10} \left\{ \left( 1 - \frac{\gamma}{\rho} \left( \frac{1}{\alpha} - 1 \right) \right) \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{\gamma}{2} \left( 1 - \frac{1}{1 - \alpha} \right) \|x_0^{k+1} - x_0^k\|^2 \right\} \\
& + \frac{4}{5} \left\{ P(x_0^{k+1}) + \frac{\gamma}{2} \|\bar{x}_k - x_0^k\|^2 - P(x_0^k) \right\} \\
& + \frac{1}{10} \left\{ \frac{\rho(1 - \beta)}{2(\frac{\gamma}{2} - 1)} \|x_k^k - \bar{x}_k\|^2 - \frac{\rho}{2(\frac{\gamma}{2} - 1)} \|\bar{x}_k - x_0^k\|^2 \right\} \\
= & \frac{1}{10} \left( 1 - \frac{\gamma}{\rho} \left( \frac{1}{\alpha} - 1 \right) \right) \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{4}{5} \left( P(x_0^{k+1}) - P(x_0^k) \right) \\
& + \left( \frac{1}{10} \cdot \frac{\gamma}{2} \left( 1 - \frac{1}{1 - \alpha} \right) + \frac{4}{5} \cdot \frac{\gamma}{2} - \frac{1}{10} \cdot \frac{\rho}{2(\frac{\gamma}{2} - 1)} \right) \|\bar{x}_k - x_0^k\|^2 \\
& + \frac{1}{10} \left( \frac{\rho(1 - \beta)}{2(\frac{\gamma}{2} - 1)} \|x_0^k - \bar{x}_k\|^2 \right) \\
\leq & \frac{1}{10} (1 - 2(\frac{1}{6} - 1)) \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{4}{5} \left( P(x_0^{k+1}) - P(x_0^k) \right) \\
& + \left( \frac{1}{10} \cdot \frac{\gamma}{2} \left( 1 - \frac{1}{1 - \alpha} \right) + \frac{4}{5} \cdot \frac{\gamma}{2} - \frac{1}{10} \cdot \frac{\gamma}{4(\frac{1}{2} - 1)} \right) \|\bar{x}_k - x_0^k\|^2 \\
& + \frac{1}{10} \left( \frac{\rho(1 - \beta)}{2(\frac{1}{2} - 1)} \|x_0^k - \bar{x}_k\|^2 \right) \\
= & \frac{3}{50} \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{4}{5} \left( P(x_0^{k+1}) - P(x_0^k) \right) \\
& + \frac{\gamma}{8} \|\bar{x}_k - x_0^k\|^2 + \frac{\gamma}{80} \|x_0^k - \bar{x}_k\|^2 \\
\geq & \frac{3}{50} \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{4}{5} \left( P(x_0^{k+1}) - P(x_0^k) \right) \\
& + \frac{\gamma}{80} \|x_0^k - \bar{x}_k\|^2, \quad (38)
\end{align*}
\]
where inequality (a) is due to Lemma 8, inequality (b) is due to the setting of \( \gamma = 2\rho, \alpha = \frac{5}{6}, \beta = \frac{1}{2} \). Inequality (c) is due to \( \|\bar{x}_k - x_0^k\|^2 \geq 0. \)
Appendix H. Proof of Lemma 8

Proof Before we prove the three results, we first state two results of Young’s inequality as follows

\[ \|x - y\|^2 = \|x - z + z - y\|^2 = \|x - z\|^2 + \|z - y\|^2 - 2\langle x - z, y - z \rangle \]

\[ \geq \|x - z\|^2 + \|z - y\|^2 - \alpha \|x - z\|^2 - \frac{1}{\alpha} \|y - z\|^2 \]

\[ = (1 - \alpha)\|x - z\|^2 + (1 - \frac{1}{\alpha})\|z - y\|^2 \]

\[ \Rightarrow \|x - z\|^2 \leq \frac{1}{1 - \alpha} \|x - y\|^2 + \frac{1}{\alpha} \|y - z\|^2 \] \hspace{1cm} (39)

\[ \Rightarrow -\|y - z\|^2 \leq -\alpha \|x - z\|^2 + \frac{\alpha}{1 - \alpha} \|x - y\|^2 \] \hspace{1cm} (40)

\[ \Rightarrow \|x - y\|^2 \geq (1 - \alpha)\|x - z\|^2 + (1 - \frac{1}{\alpha})\|y - z\|^2, \] \hspace{1cm} (41)

where \(0 < \alpha \leq 1\).

We first consider the result 1).

\(\widehat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1})\)

\[= \hat{f}_{k+1}(x_0^{k+1}, \hat{y}_{k+1}(x_0^{k+1})) - \hat{f}_{k+1}(\hat{x}_{k+1}(y_0^{k+1}), y_0^{k+1})\]

\[= f(x_0^{k+1}, \hat{y}_{k+1}(x_0^{k+1})) + \frac{\gamma}{2} \|x_0^{k+1} - x_{k+1}^{k+1}\|^2 \]

\[\quad - f(\hat{x}_{k+1}(y_0^{k+1}), y_0^{k+1}) - \frac{\gamma}{2} \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 \]

\[= f(x_0^{k+1}, \hat{y}_{k+1}(x_0^{k+1})) + \frac{\gamma}{2} \|x_0^{k+1} - x_{k+1}^{k+1}\|^2 - f(\hat{x}_{k+1}(y_0^{k+1}), y_0^{k+1}) - \frac{\gamma}{2} \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 \]

\[\quad + \frac{\gamma}{2} \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 - \frac{\gamma}{2} \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 - \frac{\gamma}{2} \|x_{k+1}^{k+1} - x_0^{k+1}\|^2 \]

\[\leq f(\bar{x}_k, \hat{y}_{k+1}(\bar{x}_k)) + \frac{\gamma}{2} \|\bar{x}_k - x_0^{k+1}\|^2 - f(\hat{x}_{k+1}(\bar{y}_k), \bar{y}_k) - \frac{\gamma}{2} \|\hat{x}_{k+1}(\bar{y}_k) - x_0^{k+1}\|^2 \]

\[\quad + \frac{\gamma}{2} \left( \frac{1}{\alpha} \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 + \frac{1}{1 - \alpha} \|x_{k+1}^{k+1} - x_0^{k+1}\|^2 \right) \]

\[\quad - \frac{\gamma}{2} \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 - \frac{\gamma}{2} \|x_{k+1}^{k+1} - x_0^{k+1}\|^2 \]

\[= \hat{f}_k(\bar{x}_k, \hat{y}_k(\bar{x}_k)) - \hat{f}_k(\bar{x}_{k+1}(\bar{y}_k), \bar{y}_k) \]

\[\quad + \frac{\gamma}{2} \left( \frac{1}{\alpha} - 1 \right) \|\hat{x}_{k+1}(y_0^{k+1}) - x_{k+1}^{k+1}\|^2 + \frac{\gamma}{2} \left( \frac{1}{1 - \alpha} - 1 \right) \|x_{k+1}^{k+1} - x_0^{k+1}\|^2 \]

\[\leq \hat{f}_k(\bar{x}_k, \hat{y}_k) + \frac{\gamma}{\rho} \left( \frac{1}{\alpha} - 1 \right) \hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{\gamma}{2} \left( \frac{1}{1 - \alpha} - 1 \right) \|x_{k+1}^{k+1} - x_0^{k+1}\|^2, \]

where inequality (a) is due to (39) \((0 < \alpha \leq 1)\). Inequality (b) is due to \(\rho\)-strong convexity of \(\hat{f}_{k+1}(x, y_0^{k+1})\) in \(x\) and optimality at \(\hat{x}_{k+1}(y_0^{k+1})\). Inequality (c) is due to \(\hat{f}_k(\hat{x}_{k+1}(\bar{y}_k), \bar{y}_k) \geq \hat{f}_k(\hat{x}_k(\bar{y}_k), \bar{y}_k)\) and \(\hat{f}_{k+1}(x_0^{k+1}, y_0^{k+1}) \leq \hat{f}_{k+1}(x_0^{k+1}, \hat{y}_{k+1}(x_0^{k+1}))\).
Re-organizing the above inequality, we have
\[ \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \geq (1 - \frac{\gamma}{\rho}(1 - 1))\hat{\text{Gap}}_{k+1}(x_0^{k+1}, y_0^{k+1}) + \frac{\gamma}{2}(1 - \frac{1}{1 - \alpha})\|x_0^{k+1} - x_0^k\|^2, \]
which proves result 1).

Then we turn to result 2) as follows.
\[ \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) = \hat{f}_k(\bar{x}_k, \bar{y}_k(\bar{x}_k)) - \hat{f}_k(\bar{x}_k(\bar{y}_k), \bar{y}_k) \]
\[ \geq \hat{f}_k(\bar{x}_k, \bar{y}_k(\bar{x}_k)) - \hat{f}_k(x_0^k, \bar{y}_k) \]
\[ \geq \hat{f}_k(\bar{x}_k, \bar{y}_k(\bar{x}_k)) - \hat{f}_k(x_0^k, \bar{y}_k(x_0^k)) \]
\[ = f(\bar{x}_k, \bar{y}_k(\bar{x}_k)) + \frac{\gamma}{2}\|\bar{x}_k - x_0^k\|^2 - f(x_0^k, \bar{y}_k(x_0^k)) - 0 \]
\[ = f(x_0^{k+1}, \bar{y}_k(x_0^{k+1})) + \frac{\gamma}{2}\|\bar{x}_k - x_0^k\|^2 - f(x_0^k, \bar{y}_k(x_0^k)) \]
\[ = P(x_0^{k+1}) - P(x_0^k) + \frac{\gamma}{2}\|\bar{x}_k - x_0^k\|^2, \]
which proves result 2).

Result 3) can be proved as follows
\[ \|\bar{x}_k - x_0^k\|^2 \geq (1 - \beta)\|x_0^k - \hat{x}_k^*\|^2 + (1 - \frac{1}{\beta})\|\hat{x}_k^* - \bar{x}_k\|^2 \]
\[ \geq (1 - \beta)\|x_0^k - \hat{x}_k^*\|^2 + (1 - \frac{1}{\beta})\frac{2}{\rho}(\hat{f}_k(\bar{x}_k, \bar{y}_k) - \hat{f}_k(\hat{x}_k^*, \bar{y}_k)) \]
\[ \geq (1 - \beta)\|x_0^k - \hat{x}_k^*\|^2 + (1 - \frac{1}{\beta})\frac{2}{\rho}\hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \]
\[ \Rightarrow \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k) \geq \rho \frac{(1 - \beta)}{2(1 - \beta)}\|x_0^k - \hat{x}_k^*\|^2 - \frac{\rho}{2(1 - \beta)}\|\bar{x}_k - x_0^k\|^2, \]
where inequality (a) is due to (41) and 0 < \beta \leq 1. Inequality (b) is due to \rho-convexity of \hat{f}_k in \bar{x}. Inequality (c) is due to 0 < \beta \leq 1 and
\[ \hat{f}_k(\bar{x}_k, \bar{y}_k) - \hat{f}_k(\hat{x}_k^*, \bar{y}_k) \leq \hat{f}_k(\bar{x}_k, \bar{y}_k(\bar{x}_k)) - \hat{f}_k(\hat{x}_k^*, \bar{y}_k) \]
\[ \leq \hat{f}_k(\bar{x}_k, \bar{y}_k(\bar{x}_k)) - \hat{f}_k(\bar{x}_k(\bar{y}_k), \bar{y}_k) \]
\[ = \hat{\text{Gap}}_k(\bar{x}_k, \bar{y}_k). \]
