I. DIVERGENCES AND DIVERGENCE STATISTICS

Many of the divergence measures used in statistics are of the $f$-divergence type introduced independently by I. Csiszár [1], T. Morimoto [2], and Ali and Silvey [3]. Such divergence measures have been studied in great detail in [4]. Often one is interested in inequalities for one $f$-divergence in terms of another $f$-divergence. Such inequalities are for instance needed in order to calculate the relative efficiency of two $f$-divergences when used for testing goodness of fit but there are many other applications. In this paper we shall study the more general problem of determining the joint range of any pair of $f$-divergences. The results are useful in determining general conditions under which information divergence is a more efficient statistic for testing goodness of fit than another $f$-divergence, but will not be discussed in this short paper.

Let $f : (0, \infty) \to \mathbb{R}$ denote a convex function satisfying $f(1) = 0$. We define $f(0)$ as the limit $\lim_{t \to 0} f(t)$. We define $f^*(t) = tf(t^{-1})$. Then $f^*$ is a convex function and $f^*(0)$ is defined as $\lim_{t \to 0} f^*(t^{-1}) = \lim_{t \to \infty} f(t)$. Assume that $P$ and $Q$ are absolutely continuous with respect to a measure $\mu$, and that $p = \frac{dP}{d\mu}$ and $q = \frac{dQ}{d\mu}$. For arbitrary distributions $P$ and $Q$ the $f$-divergence $D_f(P, Q) \geq 0$ is defined by the formula

$$D_f(P, Q) = \int_{\{q > 0\}} f\left(\frac{p}{q}\right) dq + f^*(0) \, P(q = 0) \quad (1)$$

(for details about the definition [1] and properties of the $f$-divergences, see [5], [4] or [6]). With this definition

$$D_f(P, Q) = D_{f^*}(Q, P).$$

Example 1: The function $f(t) = |t - 1|$ defines the $L^1$-distance

$$\|P - Q\| = \sum_{j=1}^k q_j |\frac{p_j}{q_j} - 1| = \sum_{j=1}^k |p_j - q_j| \quad (\text{cf. } (1)) \quad (2)$$

which plays an important role in information theory and mathematical statistics (cf. [7] or [8]).

In (1) is often taken the convex function $f$ which is one of the power functions $\phi_\alpha$ of order $\alpha \in \mathbb{R}$ given in the domain $t > 0$ by the formula

$$\phi_\alpha(t) = \frac{t^\alpha - \alpha(t - 1) - 1}{\alpha(\alpha - 1)} \quad \text{when } \alpha(\alpha - 1) \neq 0 \quad (3)$$

and by the corresponding limits

$$\phi_0(t) = -\ln t + t - 1 \quad \text{and } \phi_1(t) = t \ln t - t + 1. \quad (4)$$

The $\phi$-divergences

$$D_\alpha(P, Q) \overset{\text{def}}{=} D_{\phi_\alpha}(P, Q), \quad \alpha \in \mathbb{R} \quad (5)$$

based on [3] and [4] are usually referred to as power divergences of orders $\alpha$. For details about the properties of power divergences, see [5] or [6]. Next we mention the best known members of the family of statistics [4], with a reference to the skew symmetry $D_\alpha(P, Q) = D_{1-\alpha}(Q, P)$ of the power divergences (5).

Example 2: The $\chi^2$-divergence or quadratic divergence

$$D_2(P, Q) = D_{-1}(Q, P) = \frac{1}{2} \sum_{j=1}^k \frac{(p_j - q_j)^2}{q_j} \quad (6)$$

Fig. 1. The joint range of total variation $V$ and information $D$ as determined in [8]. It was also proved that any point in the range

$$D(P\|Q)$$

and by the corresponding limits

$$\phi_0(t) = -\ln t + t - 1 \quad \text{and } \phi_1(t) = t \ln t - t + 1. \quad (4)$$

The $\phi$-divergences

$$D_\alpha(P, Q) \overset{\text{def}}{=} D_{\phi_\alpha}(P, Q), \quad \alpha \in \mathbb{R} \quad (5)$$

based on [3] and [4] are usually referred to as power divergences of orders $\alpha$. For details about the properties of power divergences, see [5] or [6]. Next we mention the best known members of the family of statistics [4], with a reference to the skew symmetry $D_\alpha(P, Q) = D_{1-\alpha}(Q, P)$ of the power divergences (5).

Example 2: The $\chi^2$-divergence or quadratic divergence

$$D_2(P, Q) = D_{-1}(Q, P) = \frac{1}{2} \sum_{j=1}^k \frac{(p_j - q_j)^2}{q_j} \quad (6)$$
leads to the well known Pearson and Neyman statistics. The information divergence
\[ D_1(P, Q) = D_0(Q, P) = \sum_{j=1}^{k} p_j \ln \frac{p_j}{q_j} \quad (7) \]
leads to the log-likelihood ratio and reversed log-likelihood ratio statistics. The symmetric Hellinger divergence
\[ D_{1/2}(P, Q) = D_{1/2}(Q, P) = H(P, Q) \]
leads to the Freeman–Tukey statistic.

Example 3: The Hellinger divergence and the total variation are symmetric in the arguments \( P \) and \( Q \). Non-symmetric divergences may be symmetrized. For instance the LeCam divergence is nothing but the symmetrized Pearson divergence given by
\[ D_{LeCam}(P, Q) = \frac{1}{2} D_2(P, \frac{P + Q}{2}) + \frac{1}{2} D_2(Q, \frac{P + Q}{2}) \]
Another symmetrized divergence is the Jensen Shannon divergence defined by
\[ JD_1(P, Q) = \frac{1}{2} D(P, \frac{P + Q}{2}) + \frac{1}{2} D(Q, \frac{P + Q}{2}) \].
The joint range of total variation with Jensen Shannon divergence was studied by Briët and Harremoës [9] and is illustrated on Figure 2.

In this paper we shall prove that the joint range of any pair of \( f \)-divergences is essentially determined by the range of distributions on a two-element set. In special cases the significance of determining the range over two-element set has been pointed out explicitly in [10]. Here we shall prove that a reduction to two-element sets can always be made.

II. JOINT RANGE OF \( f \)-DIVERGENCES

In this section we are interested in the range of the map \((P, Q) \rightarrow (D_f(P, Q), D_g(P, Q))\) where \( P \) and \( Q \) are probability distributions on the same set.

Definition 4: A point \((x, y) \in \mathbb{R}^2\) is a \((f, g)\)-divergence pair if there exist a Borel space \((X, \mathcal{F})\) with probability measures \( P \) and \( Q \) such \((x, y) = (D_f(P, Q), D_g(P, Q))\). A \((f, g)\)-divergence pair \((x, y)\) is achievable in \(\mathbb{R}^2\) if there exist probability vectors \( P, Q \in \mathbb{R}^d \) such that
\[(x, y) = (D_f(P, Q), D_g(P, Q)) \]

Lemma 5: Assume that
\[ P_0(A) = Q_0(A) = 1 \]
and
\[ P_1(B) = Q_1(B) = 1 \]
and that \( A \cap B = \emptyset \). If \( P_\alpha = (1 - \alpha) P_0 + \alpha P_1 \) and \( Q_\alpha = (1 - \alpha) Q_0 + \alpha Q_1 \) then
\[ D_f(P_\alpha, Q_\alpha) = (1 - \alpha) D_f(P_0, Q_0) + \alpha D_f(P_1, Q_1) \]

Theorem 6: The set of \((f, g)\)-divergence pairs is convex.

Proof: Assume that \((P, Q)\) and \((\hat{P}, \hat{Q})\) are two pairs of probability distributions on a space \((\mathcal{X}, \mathcal{F})\). Introduce a two-element set \( B = \{0, 1\} \) and the product space \(\mathcal{X} \times B\) as a measurable space. Let \( \phi \) denote projection on \( B \). Now we define a pair \((\hat{P}, \hat{Q})\) of joint distribution on \(\mathcal{X} \times B\). The marginal distribution of both \( \hat{P} \) is \( \hat{Q} \) on \( B \) is \((1 - \alpha, \alpha) \). The conditional distributions are given by \( P(\cdot | \phi = i) = P_i \) and \( Q(\cdot | \phi = i) = Q_i \) where \( i = 0, 1 \). Then
\[ \left( \begin{array}{c} D_f(P_\alpha, Q_\alpha) \\ D_g(P_\alpha, Q_\alpha) \end{array} \right) = \left( \begin{array}{c} (1 - \alpha) D_f(P_0, Q_0) + \alpha D_f(P_1, Q_1) \\ (1 - \alpha) D_g(P_0, Q_0) + \alpha D_g(P_1, Q_1) \end{array} \right) \]
\[ = (1 - \alpha) \left( \begin{array}{c} D_f(P_0, Q_0) \\ D_g(P_0, Q_0) \end{array} \right) + \alpha \left( \begin{array}{c} D_f(P_1, Q_1) \\ D_g(P_1, Q_1) \end{array} \right) \]
\[ = (1 - \alpha) \left( \begin{array}{c} D_f(P, Q) \\ D_g(P, Q) \end{array} \right) + \alpha \left( \begin{array}{c} D_f(\hat{P}, \hat{Q}) \\ D_g(\hat{P}, \hat{Q}) \end{array} \right) \]

Example 7: For the joint range of total variation and Jensen Shannon divergence illustrated on Figure 2 the set of pairs achievable in \(\mathbb{R}^2\) is not convex but the set of pairs achievable in \(\mathbb{R}^3\) is convex and equals the set of all \((f, g)\)-divergence pairs.

Theorem 8: Any \((f, g)\)-divergence pair is a convex combination of two \((f, g)\)-divergence pairs, both of them achievable in \(\mathbb{R}^2\). Consequently, any \((f, g)\)-divergence pair is achievable in \(\mathbb{R}^4\).

Proof: Let \( P \) and \( Q \) denote probability measures on the same measurable space. Define the set \( A = \{ q > 0 \} \) and the function \( X = p/q \) on \( A \). Then \( Q \) satisfies
\[ \int_A X \ dQ \leq 1. \quad (8) \]
Now we fix $X$ and $A$. The formulas for the divergences become

$$D_f(P, Q) = \int_A f(X) \, dQ + f^*(0) \, P(\mathcal{C}A)$$

$$= \int_A f(X) \, dQ + f^*(0) \left(1 - \int_A X \, dQ\right)$$

$$= \int_A (f(X) + f^*(0) (1 - X)) \, dQ$$

$$= E[f(X) + f^*(0) (1 - X)]$$

and similarly

$$D_g(P, Q) = E[g(X) + g^*(0) (1 - X)].$$

Hence, the divergences only depend on the distribution of $X$. Therefore we may without loss of generality assume that $Q$ is a probability measure on $[0, \infty)$.

Define $C$ as the set of probability measures on $[0, \infty)$ satisfying $E[X] \leq 1$. Let $C^+$ be the set of additive measures $\mu$ on $[0, \infty)$ satisfying $\mu(A) \leq 1$ and $\int_A X \, d\mu \leq 1$. Then $C^+$ is convex and thus compact under setwise convergence. According to the Choquet–Bishop–de Leeuw theorem [11] any other point in $C^+$ is the barycenter of a probability measure over such extreme points. In particular an element $Q \in C$ is the barycenter of a probability measure $P_{\text{bary}}$ over extreme points of $C^+$ and these extreme points must in addition be probability measures with $P_{\text{bary}}$-probability 1. Hence $Q \in C$ is a barycenter of a probability measure over extreme points in $C$.

Let $Q$ be an element in $C$. Let $A_i, i = 1, 2, 3$ be a disjoint cover of $[0, \infty)$ and assume that $Q(A_i) > 0$. Then

$$Q = \sum_{i=1}^3 Q(A_i) Q(\cdot \mid A_i).$$

For a probability vector $\lambda = (\lambda_1, \lambda_2, \lambda_3)$ let $Q_\lambda$ denote the distribution

$$Q_\lambda = \sum_{i=1}^3 \lambda_i Q(\cdot \mid A_i).$$

Then $Q_\lambda$ is element in $C$ if and only if

$$\sum_{i=1}^3 \lambda_i \int_A X \, dQ(\cdot \mid A_i) \leq 1. \quad (9)$$

An extreme probability vector $\lambda$ that satisfies (9) has one or two of its weights equal to 0. Hence, if $Q$ is extreme in $C$ and $A_i, i = 1, 2, 3$ is a disjoint cover of $A$, then at least one of the three sets satisfies $Q(A_i) = 0$. Therefore an extreme point $Q \in C$ is of one of the following two types:

1. $Q$ is concentrated in one point.
2. $Q$ has support on two points. In this case the inequality $\int_A X \, dQ \leq 1$ holds with equality and $P(A) = 1$ so that $P$ is absolutely continuous with respect to $Q$ and therefore supported by the same two-element set.

The formulas for divergence are linear in $Q$. Hence any $(f, g)$-divergence pair is a barycenter of a probability measure $P_{\text{bary}}$ over pairs generated by extreme distributions $Q \in C$. The extreme distributions of type 2 generate pairs achievable in $\mathbb{R}^2$.

For extreme points $Q$ concentrated in a single point we can reverse the argument at make a barycentric decomposition with respect to $P$. If an extreme $P$ has a two-point support then $Q$ is absolutely continuous with respect to $P$ and generates a $(f, g)$-divergence pair achievable in $\mathbb{R}^2$. If $P$ is concentrated in a point then this point may either be identical with the support of $Q$ and the two probability measures are identical, or the support points are different and $P$ and $Q$ are singular but still $(P, Q)$ is supported on two points. Therefore any $(f, g)$-divergence pair has a barycentric decomposition into pairs achievable in $\mathbb{R}^2$.

Let $y = (y, z)$ be a $(f, g)$-divergence pair. As we have seen $y$ is a barycenter of $(f, g)$-divergence pairs achievable in $\mathbb{R}^2$. According to the Carathéodory’s theorem [12] any barycentric decomposition in two dimensions may be obtained as a convex combination of at most three points $y_i, i = 1, 2, 3$, as illustrated in Figure 3. Assume that all three points have positive weight. Let $\ell_i$ be the line through $y$ and $y_i$. The point $y$ divides the line $\ell_i$ in two half-lines $\ell_i^+$ and $\ell_i^-$, where $\ell_i^+$ denotes the halfline that contains $y_i$. The lines $\ell_i^+, i = 1, 2, 3$ divide $\mathbb{R}^2$ into three sectors, each of them containing one of the points $y_i, i = 1, 2, 3$. The set of $(f, g)$-divergence pairs achievable in $\mathbb{R}^3$ is curve-connected so there exist a continuous curve of $(f, g)$-divergence pairs achievable in $\mathbb{R}^2$ from $y_1$ to $y_2$ that must intersect $\ell_i^+ \cup \ell_i^-$ in a point $z$. If $z$ lies on $\ell_i^+$ then $y$ is a convex combination of the two points $y_i$ and $z$. Hence, any $(f, g)$-divergence pair is a convex combination of two points that are $(f, g)$-divergence pairs achievable in $\mathbb{R}^2$. From the construction in the proof of Theorem 6 we see that any $(f, g)$-divergence pair is achievable in $\mathbb{R}^4$.

Remark 9: We do not have any example of functions $(f, g)$ such that the set of pairs achievable in $\mathbb{R}^3$ is not convex.

Remark 10: An $f$-divergence on a arbitrary $\sigma$-algebra can be approximated by the $f$-divergence on its finite subalgebras. Any finite $\sigma$-algebra is a Borel $\sigma$-algebra for discrete space so for probability measures $P, Q$ on a $\sigma$-algebra
the point \((D_f(P,Q),D_g(P,Q))\) in the closure of the pairs achievable in \(\mathbb{R}^4\). For many function pairs \(((f,g))\) the set of pairs achievable in \(\mathbb{R}^2\) is closed and then the set of all \((f,g)\)-divergence pairs is closed and contains \((D_f(P,Q),D_g(P,Q))\) even if \(P, Q\) are measures on a non-atomic \(\sigma\)-algebra.

The set of \((f,g)\)-divergence pairs that are achievable in \(\mathbb{R}^2\) can be parametrized as \(P = (1 - p, p)\) and \(Q = (1 - q, q)\). If we define \((1 - p, p) = (p, 1 - p)\) then \(D_f(P, Q) = D_f(\overline{P}, \overline{Q})\). Hence we may assume without loss of generality assume that \(p \leq q\) and just have to determine the image of the simplex \(\Delta = \{(p, q) \mid 0 \leq p \leq q \leq 1\}\). This result makes it very easy to make a numerical plot of the \((f,g)\)-divergence pair achievable in \(\mathbb{R}^2\) and the joint range is just the convex hull.

### III. Image of the Triangle

In order to determine the image of the triangle \(\Delta\) we have to check what happens at inner points and what happens at or near the boundary. Most inner points are mapped into inner points of the range. On subsets of \(\Delta\) where the derivative matrix is non-singular the mapping \((P, Q) \rightarrow (D_f, D_g)\) is open according to the open mapping theorem from calculus. Hence, all inner points that are not mapped into interior points of the range must satisfy

\[
\begin{vmatrix}
\frac{\partial D_f}{\partial p} & \frac{\partial D_f}{\partial q} \\
\frac{\partial D_g}{\partial p} & \frac{\partial D_g}{\partial q}
\end{vmatrix} = 0.
\]

Depending on functions \(f\) and \(g\) this equation may be easy or difficult to solve, but in most cases the solutions will lie on a 1-dimensional manifold that will cut the triangle \(\Delta\) into pieces, such that each piece is mapped isomorphically into subsets of the range of \((P, Q) \rightarrow (D_f, D_g)\). Each pair of functions \((f, g)\) will require its own analysis.

The diagonal \(p = q\) in \(\Delta\) is easy to analyze. It is mapped into \((D_f, D_g) = (0, 0)\).

**Lemma 11:** If \(f(0) = \infty\), and \(\lim_{t \to 0} \inf \frac{g(t)}{f(t)} = \beta_0\), then the supremum of

\[
\beta : D_f(P, Q) - D_g(P, Q)
\]

over all distributions \(P, Q\) is \(\infty\) if \(\beta > \beta_0\).

If \(f^*(0) = \infty\), and \(\lim_{t \to \infty} \inf \frac{g(t)}{f(t)} = \beta_0\), then the supremum of

\[
\beta : D_f(P, Q) - D_g(P, Q)
\]

over all distributions \(P, Q\) is \(\infty\) if \(\beta > \beta_0\).

If \(g(0) = \infty\), and \(\lim_{t \to 0} \sup \frac{g(t)}{f(t)} = \gamma_0\), then the supremum of

\[
D_g(P, Q) - \gamma D_f(P, Q)
\]

over all distributions \(P, Q\) is \(\infty\) if \(\gamma < \gamma_0\).

If \(g^*(0) = \infty\), and \(\lim_{t \to \infty} \sup \frac{g(t)}{f(t)} = \gamma_0\), then the supremum of

\[
D_g(P, Q) - \gamma D_f(Q, P)
\]

over all distributions \(P, Q\) is \(\infty\) if \(\gamma < \gamma_0\).

**Proof:** Assume that

\[
f(0) = \infty \quad \text{and} \quad \lim_{t \to 0} \inf \frac{g(t)}{f(t)} = \beta_0.
\]

The first condition implies

\[
D_f((1, 0), (1/2, 1/2)) = \infty
\]

and the second condition implies \(g(0) = \infty\) and

\[
D_g((1, 0), (1/2, 1/2)) = \infty.
\]

We have

\[
\frac{D_g((p, 1 - p), (1/2, 1/2))}{D_f((p, 1 - p), (1/2, 1/2))}
= \frac{g(2p)/2 + g(2(1 - p))/2}{f(2p)/2 + f(2(1 - p))/2}
= \frac{g(2p) + g(2(1 - p))}{f(2p) + f(2(1 - p))}.
\]

Let \((t_n)_n\) be a sequence such that \(\frac{g(t_n)}{f(t_n)} \to \beta\) for \(n \to \infty\). Then

\[
\frac{D_g((\frac{t_n}{2}, 1 - \frac{t_n}{2}), (1/2, 1/2))}{D_f((\frac{t_n}{2}, 1 - \frac{t_n}{2}), (1/2, 1/2))} \to \beta
\]

and the first result follows.

The other three cases follow by interchanging \(f\) and \(g\), and/or replacing \(f\) by \(f^*\) and \(g\) by \(g^*\). We have used that

\[
\lim_{t \to \infty} \frac{g^*(t)}{f^*(t)} = \lim_{t \to 0} \frac{g(t)}{f(t)} = \lim_{t \to \infty} \frac{g(t)}{f(t)}.
\]

**Proposition 12:** Assume that \(f\) and \(g\) are \(C^2\) and that \(f''(1) > 0\) and \(g''(1) > 0\). Assume that \(\lim_{t \to 0} \inf \frac{g(t)}{f(t)} > 0\), and that \(\lim_{t \to \infty} \inf \frac{g(t)}{f(t)} > 0\). Then there exists \(\beta > 0\) such that

\[
D_g(P, Q) \geq \beta \cdot D_f(P, Q)
\]

for all distributions \(P, Q, Q\).

**Proof:** The inequality \(\lim_{t \to \infty} \inf \frac{g(t)}{f(t)} > 0\) implies that there exist \(\beta_0, t_0 > 0\) such that \(g(t) \geq \beta_0 f(t)\) for \(t < t_0\).

The inequality \(\lim_{t \to \infty} \inf \frac{g(t)}{f(t)} > 0\) implies that there exists \(\beta_\infty > 0\) and \(t_\infty > 0\) such that \(g(t) \geq \beta_\infty f(t)\) for \(t > t_\infty\).

According to Taylor’s formula we have

\[
f(t) = \frac{f''(\theta)(t - 1)^2}{2},
\]

\[
g(t) = \frac{g''(\eta)(t - 1)^2}{2}
\]

for some \(\theta\) and \(\eta\) between 1 and \(t\). Hence

\[
\frac{g(t)}{f(t)} \to \frac{f''(1)}{g''(1)}\text{ for }t \to 1.
\]

Therefore there there exists \(\beta_1 > 0\) and an interval \([t_-, t_+]\) around 1 such that \(\frac{g(t)}{f(t)} \geq \beta_1\) for \(t \in [t_-, t_+]\). The function \(t \to \frac{g(t)}{f(t)}\) is continuous on the compact set \([t_0, t_-] \cup [t_+, t_\infty]\) so it has a minimum \(\tilde{\beta} > 0\) on this set. Inequality [10] holds for \(\beta = \min \{\beta_0, \beta_1, \beta_\infty, \tilde{\beta}\}\).
IV. BOUNDS FOR POWER DIVERGENCES

As an example we shall determine the exact range of a pair of power divergences. We have

\[ f(t) = \phi_2(t), \]
\[ g(t) = \phi_3(t). \]

In this case we have

\[ D_f ((p, 1-p), (q, 1-q)) = \frac{1}{2} \left( \frac{(p-q)^2}{q} + \frac{(p-q)^2}{1-q} \right), \]
\[ D_g ((p, 1-p), (q, 1-q)) = \frac{1}{6} \left( \left( \frac{p}{q} \right)^3 q + \left( \frac{1-p}{1-q} \right)^3 (1-q) - 1 \right). \]

First we determine the image of the triangle. The derivatives are

\[ \frac{\partial D_f}{\partial p} = \frac{2}{2} \left( \frac{p-q}{(1-q)q} \right), \]
\[ \frac{\partial D_f}{\partial q} = \frac{1}{2} \left( \frac{2pq - q - p}{(1-q)q^2} \right), \]
\[ \frac{\partial D_g}{\partial p} = -3, \left( \frac{2(pq - p)(p-q)}{(1-q)^2 q^4} \right), \]
\[ \frac{\partial D_g}{\partial q} = \frac{2}{6} \left( \left( \frac{pq + p^2 + q^2}{3pq^3 - 3pq^2 + 3pq^2} \right) (p-q) \right). \]

The determinant of derivatives is

\[ \left| \begin{array}{cc}
\frac{\partial D_f}{\partial p} & \frac{\partial D_f}{\partial q} \\
\frac{\partial D_g}{\partial p} & \frac{\partial D_g}{\partial q}
\end{array} \right| = \frac{(p-q)^2}{12q^4(1-q)^4} \left| \begin{array}{c}
2 pq - q - p \\
2pq - q - p - 6pq - 6pq^2 - 2p^2 - 2q^2 - 2pq + 6pq^2 - 6pq^2 \end{array} \right| = -\frac{1}{12} \left( \frac{p-q}{q(1-q)} \right)^4. \]

We see that the determinant of derivatives is different from zero for \( p \neq q \) so the interior of \( \Delta \) is mapped one-to-one to the image. Hence we just have to determine the image of points on the boundary of \( \Delta \) (or near the boundary if undefined on the boundary).

For \( P = (1,0) \) and \( Q = (1-q, q) \) we get

\[ D_f (P, Q) = \frac{1}{2} \left( q + \frac{q^2}{1-q} \right) = \frac{1}{2} \left( \frac{1}{1-q} - 1 \right), \]
\[ D_g (P, Q) = \frac{1}{6} \left( \frac{1}{(1-q)^2} - 1 \right) = \frac{1}{6} \left( \frac{(2-q)q}{1-q} \right). \]

The first equation leads to

\[ q = \left( 1 - \frac{1}{2D_f + 1} \right) \]

and hence

\[ D_g = \frac{2}{3} D_f (D_f + 1). \]

We have

\[ \frac{f(t)}{g(t)} = \frac{t^2 - 2(t-1)-1}{2t^2 - 3(t-1)-1} \rightarrow \infty \text{ for } t \rightarrow \infty. \]

All points \((0, s), s \in [0, \infty)\) are in the closure of the range of \((P, Q) \rightarrow (D_f, D_g)\). By combining these two results we see that the range consists of the point \((0,0)\), all points on the curve \( (x, \frac{2}{3} x (x + 1)) \), \( x \in (0, \infty) \), and all point above this curve.

Similar results holds for any pair of power divergences, but for other pairs than \((D_2, D_3)\) the computations become much more involved.

Note that the Rényi divergences are monotone functions of the power divergences so our results easily translate into the results on Rényi divergences. More details on Rényi divergences can be found in [13].

V. ACKNOWLEDGEMENT

The authors thank Job Briët and Tim van Erven for comments to a draft of this paper.

This work was supported by the European Network of Excellence and the GAČR grants 102/07/1131 and 202/10/0618.
