On Douglas–Rachford operators that fail to be proximal mappings

Heinz H. Bauschke*, Jason Schaad†, and Xianfu Wang‡

February 17, 2016

Abstract

The problem of finding a zero of the sum of two maximally monotone operators is of central importance in optimization. One successful method to find such a zero is the Douglas–Rachford algorithm which iterates a firmly nonexpansive operator constructed from the resolvents of the given monotone operators.

In the context of finding minimizers of convex functions, the resolvents are actually proximal mappings. Interestingly, as pointed out by Eckstein in 1989, the Douglas–Rachford operator itself may fail to be a proximal mapping. We consider the class of symmetric linear relations that are maximally monotone and prove the striking result that the Douglas–Rachford operator is generically not a proximal mapping.

2010 Mathematics Subject Classification: Primary 47H09, Secondary 47H05, 90C25.

Keywords: Douglas–Rachford algorithm, firmly nonexpansive mapping, maximally monotone operator, nowhere dense set, proximal mapping, resolvent.

1 Introduction

Throughout this paper, we work in the standard Euclidean space

\[ X = \mathbb{R}^n, \]

equipped with the standard inner product \( \langle \cdot, \cdot \rangle \) and induced Euclidean norm \( \| \cdot \| \). Recall that a set-valued operator

\[ A: X \rightrightarrows X \] (2)

is monotone if \( \langle x - y, x^* - y^* \rangle \geq 0 \) whenever \( (x, x^*) \) and \( (y, y^*) \) belong to \( \text{gra} A \), the graph of \( A \); \( A \) is maximally monotone if any proper enlargement of \( A \) fails to be monotone. Maximally monotone operators are of importance in modern optimization (see \cite{1, 2, 5, 6, 7, 8, 9, 11, 22}) as they cover subdifferential operators of functions that are convex lower semicontinuous and proper as well as matrices whose symmetric part is positive semidefinite. A central problem is to

\[ \text{find } x \in X \text{ such that } 0 \in Ax + Bx, \] (3)

where \( A \) and \( B \) are maximally monotone on \( X \). For instance, if \( A = \partial f \) and \( B = \partial g \), where \( f \) and \( g \) belong to \( \Gamma_0(X) \), the set of functions that are convex, lower semicontinuous and proper on \( X \), then the sum problem (3) is tied to the problem of finding a minimizer of \( f + g \). A popular iterative method, dating back to Lions and Mercier’s seminal work \cite{14}, to solve (3) is the Douglas–Rachford algorithm whose governing sequence \( (x_n)_{n \in \mathbb{N}} \) is given by

\[ (\forall n \in \mathbb{N}) \quad x_{n+1} = T_{A,B}x_n, \] (4)

where \( T_{A,B} = \text{Id} - J_A + J_BR_A = (\text{Id} + R_BR_A)/2 \) is the Douglas–Rachford splitting operator, \( J_A = (\text{Id} + A)^{-1} \) is the resolvent of \( A \) and and \( R_A = 2J_A - \text{Id} \) is the reflected resolvent. If \( Z \), the set of solutions (3), is nonempty, then \( (x_n)_{n \in \mathbb{N}} \) converges to a fixed point of \( T_{A,B} \) and \( (J_Ax_n)_{n \in \mathbb{N}} \) converges to a point in \( Z \). In fact, as pointed in \cite{14}, one has \( T_{A,B} = J_C \) for some maximally monotone operator \( C \) depending on \( (A, B) \). That is, (4) is actually the iteration of a resolvent — the resulting method was carefully studied by Rockafellar \cite{19}. If the operator \( C \) is actually a subdifferential operator, i.e., \( C = \partial h \), where \( h \in \Gamma_0(X) \); or equivalently if \( J_C \) is a proximal map (a.k.a. proximity operator) \cite{16}, then stronger statements are available concerning the resolvent iteration \cite{13}. This prompts interest in the question whether \( C = \partial h \). Unfortunately, in general, \( T_{A,B} = J_C \) is only a resolvent, not a proximal map as demonstrated by Eckstein \cite{10}; the following simpler example is from Schaad’s thesis \cite{21}. Suppose that \( X = \mathbb{R}^2 \), and that \( A \) and \( B \) are the normal cone operators of the subspaces \( \mathbb{R}(1,0) \) and \( \mathbb{R}(1,1) \). Then the associated maximally monotone operator is given by the matrix

\[ C = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \] (5)
which is not symmetric and hence $C$ is not a subdifferential operator. The corresponding Douglas–Rachford operator

$$J_C = T_{A,B} = \frac{1}{2} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix},$$

which is also not symmetric, is therefore only a resolvent but not a proximal mapping. This is surprising because (3) corresponds in this case to the convex feasibility problem asking to find a point in $\mathbb{R}(1,0) \cap \mathbb{R}(1,1)$ (which is $\{(0,0)\}$).

In this note paper we show that in the context of linear relations it is generically the case that the Douglas–Rachford operator is only a resolvent and not a proximal mapping.

The rest of the paper is organized as follows. In Section 2, we develop auxiliary results on matrices, proximal mappings and convergence. Section 3 contains our main result.

Finally, notation and notions not explicitly defined may be found in, e.g., [2], [15], [18], or [20].

2 Auxiliary results

2.1 Matrices

Unless stated otherwise, we view $\mathbb{R}^{n \times n}$, the set of real $n \times n$ matrices, as a Banach space, with norm $\|R\| := \sup_{\|x\| \leq 1} \|Rx\|$, which is the square root of the largest eigenvalue of $R^T R$. We denote by $S^n$ the subspace of symmetric $n \times n$ matrices. A matrix $R$ is nonexpansive if $\|R\| \leq 1$, i.e., $R$ belongs to the unit ball of $\mathbb{R}^{n \times n}$. This set is convex, closed, and has 0 in its interior. The set of nonexpansive symmetric matrices is likewise in $S^n$.

**Lemma 2.1.** Let $R_0, S_0, R_1, S_1$ be matrices in $\mathbb{R}^{n \times n}$. Suppose that $R_0$ commutes with $S_0$, but that $R_1$ does not commute with $S_1$. For each $\lambda \in ]0,1[$, set $R_\lambda = (1-\lambda)R_0 + \lambda R_1$ and set $S_\lambda = (1-\lambda)S_0 + \lambda S_1$. Then $\{\lambda \in ]0,1[ \mid R_\lambda \text{ commutes with } S_\lambda\}$ is either empty or a singleton.

**Proof.** For $\lambda \in ]0,1[$, consider the matrix

$$M_\lambda = R_\lambda S_\lambda - S_\lambda R_\lambda.$$  

(7)

By hypothesis, $M_0 = 0$ but $M_1 \neq 0$. Since $M_1 \neq 0$, there exist $(i,j) \in \{1, \ldots, n\}^2$ such that the $(i,j)$ entry of $M_1$ is not 0. Denote by $q(\lambda)$ the $(i,j)$ entry of $M_\lambda$. Then $q(\lambda)$ is a polynomial in $\lambda$ of degree at most 2, with $q(0) = 0$ and $q(1) \neq 0$. On $]0,1[$, $q$ has at most one root. Therefore, with the possible exception of one value $\lambda \in ]0,1[$, $M_\lambda \neq 0$. ■
Example 2.2. Suppose that \( n \geq 2 \) and define matrices in \( S^n \) by
\[
R_0 = R_1 = \begin{bmatrix}
1 & 0 & 0 \\
0 & -1 & 0 \\
0 & 0 & 0
\end{bmatrix},
\quad
S_0 = \begin{bmatrix}
-1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 0
\end{bmatrix},
\quad
S_1 = \begin{bmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}.
\] (8)

For each \( \lambda \in ]0, 1[ \), set \( R_\lambda = (1 - \lambda)R_0 + \lambda R_1 \) and set \( S_\lambda = (1 - \lambda)S_0 + \lambda S_1 \). Let \( \lambda \in [0, 1] \).

Then
\[
\|R_\lambda\| = 1, \quad \|S_\lambda\| = \sqrt{(1 - \lambda)^2 + \lambda^2} \in [1/\sqrt{2}, 1]
\] (9)

and
\[
R_\lambda S_\lambda = \begin{bmatrix}
\lambda - 1 & \lambda & 0 \\
-\lambda & \lambda - 1 & 0 \\
0 & 0 & 0
\end{bmatrix},
\quad
S_\lambda R_\lambda = \begin{bmatrix}
\lambda - 1 & -\lambda & 0 \\
\lambda & \lambda - 1 & 0 \\
0 & 0 & 0
\end{bmatrix}.
\] (10)

Consequently, \( R_\lambda \) commutes with \( S_\lambda \) if and only if \( \lambda = 0 \).

2.2 Proximal mappings

We now characterize proximal mappings within the set of resolvents.

Lemma 2.3. [21, Lemma 4.36] Let \( T \in \mathbb{R}^{n \times n} \) be a proximal mapping. Then \( T = T^T \).

Proof. Set \( q : x \mapsto \frac{1}{2}\|x\|^2 \). Then \( \text{Id} = \nabla q \). By hypothesis, \( T \) is a proximal mapping, so there exists a convex \( f \) such that
\[
T = (\text{Id} + \partial f)^{-1} = (\partial(q + f))^{-1} = \partial(q + f)^* = \nabla(q + f)^*.
\] (11)

It follows that \( T = \nabla T = \nabla^2(q + f)^* \) is symmetric. \( \blacksquare \)

It turns out that the converse of the previous result also holds.

Lemma 2.4. Let \( T \in \mathbb{R}^{n \times n} \) be firmly nonexpansive\footnote{For further information on firmly nonexpansive mappings, see [2] and [12].} and such that \( T = T^T \). Then \( T \) is a proximal mapping.

Proof. Set \( f : X \to \mathbb{R} : x \mapsto \frac{1}{2} \langle x, Tx \rangle \). Since \( T \) is symmetric, we have \( \nabla f = T \). Since \( T \) is firmly nonexpansive, it is monotone and thus \( f \) is convex. By the (extended form of the) Baillon–Haddad theorem (see [2] Theorem 18.15]), \( \nabla f = T \) is a proximal map. \( \blacksquare \)

We thus obtain the following useful characterization of proximal mappings.
Corollary 2.5. Let $T \in \mathbb{R}^{n \times n}$. Then $T$ is a proximal mapping if and only if $T$ is both firmly nonexpansive and symmetric.

2.3 Convergence

From now on, we denote the set of maximally monotone operators on $X$ by $\mathcal{M}$, the subset of linear relations by $\mathcal{L}$, and the subdifferential operators of functions in $\Gamma_0(X)$ by $\mathcal{S}$.

Let $(A_k)_{k \in \mathbb{N}}$ be a sequence in $\mathcal{M}$ and let $A \in \mathcal{M}$. Then $(A_k)_{k \in \mathbb{N}}$ converges to $A$ graphically, in symbols $A_k \xrightarrow{\text{g}} A$ if and only if the resolvents converge pointwise, in symbols, $J_{A_k} \overset{p}{\to} J_A$. This induces a metric topology on $\mathcal{M}$ (see [20] for details). Note that $\mathcal{L}$ is a closed topological subspace of $\mathcal{M}$ and that pointwise convergence by resolvents can in that setting be replaced by convergence in operator norm (since $X$ is finite-dimensional).

The following result is now easily verified.

Proposition 2.6. Let $(A_k)_{k \in \mathbb{N}}$ be a sequence in $\mathcal{L}$, and let $A \in \mathcal{L}$. Then we have the equivalences

$$A_k \xrightarrow{\text{g}} A \iff J_{A_k} \overset{p}{\to} J_A \iff R_{A_k} \overset{p}{\to} R_A \iff J_{A_k} \to J_A \iff R_{A_k} \to R_A. \quad (12)$$

We thus are able to define a metric on $\mathcal{L}$ by

$$(A_1, A_2) \mapsto \|J_{A_1} - J_{A_2}\| \quad (13)$$

and a metric on $\mathcal{L} \times \mathcal{L}$ by

$$((A_1, B_1), (A_2, B_2)) \mapsto \|J_{A_1} - J_{A_2}\| + \|J_{B_1} - J_{B_2}\|. \quad (14)$$

Note that in view of the pointwise characterization of Proposition 2.6, both $\mathcal{L}$ and $\mathcal{L} \times \mathcal{L}$ are complete and so are $\mathcal{L} \cap \mathcal{S}$ and $(\mathcal{L} \cap \mathcal{S}) \times (\mathcal{L} \cap \mathcal{S})$.

These topological notions are used in the next section which contains our main result.

3 Main result

Recall that for $A$ and $B$ in $\mathcal{M}$, the Douglas–Rachford operator is defined by

$$T(A, B) = T_{(A,B)} = \frac{1}{2}(\text{Id} + R_BR_A). \quad (15)$$

\textsuperscript{2}A linear relation on $X$ is set-valued map from $X$ to $X$ such that its graph is a linear subspace of $X \times X$. In relationship to the present paper, we refer the reader to [4] for more on maximally monotone linear relations. Furthermore, a resolvent $J_A$ is linear if and only if $A \in \mathcal{L}$ by [3, Theorem 2.1(xviii)].
Note that $T_{(A,B)}$ is firmly nonexpansive and the resolvent of some maximally monotone operator $M(A,B) \in \mathcal{M}$ but it may be the case that $M(A,B) \notin S$ even when $A$ and $B$ belong to $S$.

We are ready for our main result.

**Theorem 3.1.** Suppose that $n \geq 2$. Then generically, the Douglas–Rachford operators for symmetric linear relations are not proximal mappings; in fact, the set

$$D := \{(A, B) \in (\mathcal{L} \cap S)^2 \mid T_{(A,B)} \text{ is a proximal map}\}$$

is a closed subset of $(\mathcal{L} \cap S)^2$ that is nowhere dense.

**Proof.** We start by verifying that $D$ is closed. To this end, let $(A_k, B_k)_{k \in \mathbb{N}}$ be a sequence in $D$ converging to $(A, B) \in (\mathcal{L} \cap S)^2$. By definition, $T(A_k, B_k)$ is a proximal mapping for every $k \in \mathbb{N}$. By Corollary 2.5 (\forall k \in \mathbb{N}) $T(A_k, B_k)^{T} = T(A_k, B_k)$. Hence (\forall k \in \mathbb{N}) $R_{A_k}R_{B_k} = R_{B_k}R_{A_k}$. In view of Proposition 2.6 we take the limit and obtain $R_AR_B = R_BR_A$. Thus $T(A, B) = T(A, B)^{T}$. Using Corollary 2.5 again, we deduce that $T(A, B)$ is a proximal map.

We now show that $D$ is nowhere dense. Let $(A_0, B_0)$ be in $D$. Then $R_{A_0}R_{B_0} = R_{B_0}R_{A_0}$. Next, set $A_1 = ((R_1 + \text{Id})/2)^{-1} - \text{Id}$ and $B_1 = ((S_1 + \text{Id})/2)^{-1} - \text{Id}$, where $R_1$ and $S_1$ are as in Example 2.2. Then $R_{A_1} = R_1$ and $R_{B_1} = S_1$ do not commute and hence $(A_1, B_1) \notin D$. Now set

$$A_\lambda = \left( \frac{1}{2} \text{Id} + \frac{1}{2}((1 - \lambda)R_{A_0} + \lambda R_{A_1}) \right)^{-1} - \text{Id} \quad (17a)$$

and

$$B_\lambda = \left( \frac{1}{2} \text{Id} + \frac{1}{2}((1 - \lambda)R_{B_0} + \lambda R_{B_1}) \right)^{-1} - \text{Id}. \quad (17b)$$

Then, as $\lambda \to 0^+$,

$$R_{A_\lambda} = (1 - \lambda)R_{A_0} + \lambda R_{A_1} \to R_{A_0} \text{ and } R_{B_\lambda} = (1 - \lambda)R_{B_0} + \lambda R_{B_1} \to R_{B_0}. \quad (18)$$

It follows from Lemma 2.1 and Corollary 2.5 that there exists $\mu \in [0, 1]$ such that (\forall $\lambda \in [0, \mu]$) $(A_\lambda, B_\lambda) \notin D$. Hence $(A_0, B_0)$ does not belong to the interior of $D$. ■

**Remark 3.2.** The assumption that $n \geq 2$ in Theorem 3.1 is important: indeed, when $n = 1$, it is well known that every maximally monotone operator is actually a subdifferential operator (see, e.g., [2, Corollary 22.19]) and therefore every Douglas–Rachford operator is a proximal mapping in this case.

**Remark 3.3 (open problems).** The following questions appear to be of interest:
(i) Does Theorem 3.1 admit an extension from symmetric linear relations to general subdifferential operators?

(ii) The set $D$ in Theorem 3.1 is closed and nowhere dense. Is it also a porous\textsuperscript{3} set?
