Abstract

Background: A number of synthetic pantothenate derivatives, such as pantothenamides, are known to inhibit the growth of the human malaria parasite Plasmodium falciparum, by interfering with the parasite Coenzyme A (CoA) biosynthetic pathway. The clinical use of pantothenamides is limited by their sensitivity to breakdown by ubiquitous human pantetheinases of the vanin family.

Methods: A number of pantothenate derivatives (pantothenones) with potent and specific inhibitory activity against mammalian vanins were tested in a proliferation assay of asexual P. falciparum blood stages alone, and in combination with pantothenamides.

Results: The vanin inhibitors were found to protect pantothenamides against breakdown by plasma vanins, thereby preserving the in vitro anti-malarial activity. Moreover, some of the vanin inhibitors showed in vitro anti-malarial activity in the low micromolar range. The most potent antimalarial in this series of compounds (RR8), was found to compete with pantothenate in a combination proliferation assay. No correlation, however, was found between anti-vanin and anti-malarial activity, nor was pantetheinase activity detected in P. falciparum extracts.

Conclusions: Growth inhibition is most likely due to competition with pantothenate, rather than pantetheinase inhibition. As vanin inhibitors of the pantothenone class are stable in biological fluids and are non-toxic to mammalian cells, they may represent novel pantothenate-based anti-malarials, either on their own or in combination with pantothenamides.

Background

Each year over half a million people die of malaria, with Plasmodium falciparum being the primary cause of fatal malaria cases [1]. As the eradication of malaria is threatened by occurrence of clinical resistance to artemisinin derivatives, new drugs for malaria are sorely needed and so the search for new lead compounds continues [1].

Based on the observation, that addition of calcium pantothenate to Plasmodium lophurae cultures increased parasite viability, a selection of analogues of pantothenate (pantothenic acid, vitamin B5), were tested for antiplasmodial activity as early as the 1940s [2]. These compounds included pantoyltaurine, substituted pantoyltaurylamides, sulphonamides, and pantothenones, according to the nomenclature used in a review on this subject by Spry et al. [3]. These and similar compounds were tested in different in vitro and in vivo malaria models from the 1960s and 1970s [4,5]. In 1976, Trager and Jensen published an article describing the continuous culture of P. falciparum [6], allowing Divo et al. to discover that pantothenate is indeed the only water soluble vitamin that needs to be exogenously available for P. falciparum survival [7]. Meanwhile, Clifton et al. prepared a series of analogues with the general structure N1-(substituted) pantothenamide, and...
found them to have antibacterial activity due to being anti-
timetabolites of pantothenate [8].

Recent studies showed that some of the pantethenam-
ides were also active against *P. falciparum in vitro*, pro-
vided that plasma pantetheinase activity was reduced [9].
This was discovered due to the observation that ‘aging’
*P. falciparum* growth media increased the anti-malarial ac-
tivity of some pantethenamides [9]. Later, this same effect
was achieved with heat inactivation of the parasite growth
medium by de Villiers *et al.* [10]. The mechanism of break-
down of pantethenamides by pantetheinases of the vanin
family was elucidated in detail by Jansen *et al.* who discov-
ered that combining pantethenamides with small molecule
vanin inhibitors, protected pantethenamides against break-
down, thereby dramatically increasing their antibacterial
activity against both *Staphylococcus aureus* and *Escherichia
coli* [11-14]. It has also been shown by de Villiers *et al.* that
small modifications of the pantethenamide core structure
could protect the molecule against pantetheinase-mediated
degradation, albeit at a cost of a 10-fold decrease in anti-
malarial potency [10].

Compounds, such as the pantethenamides in *E. coli* or
the fungal product CJ-15,801 in *S. aureus* may hijack
Coenzyme A (CoA) biosynthesis, being phosphorylated
in the first step of the biosynthesis by pantetheinase kin-
ase (PanK) and eventually blocking CoA production or
interfering with fatty acid synthesis downstream along
the pathway [15-17]. Almost a decade ago, the fungal
product CJ-15,801, was also discovered to have modest
anti-malarial activity against asexual intra-erythrocytic
stages of *P. falciparum in vitro*, and was demonstrated to
inhibit parasite growth by a mechanism related to CoA
biosynthesis or utilization [18].

In this study a selection of novel pantetheine analogues
of the pantathenate class were investigated for potential
use as anti-malarial chemotherapy. The investigated com-
ounds are shown to be conceptually promising either as
a monotherapy or in a combination of drugs.

**Methods**

**Compounds**

Pantothenol was purchased from Sigma-Aldrich. De-
tailed synthesis procedures of CJ-15,801 and CXP14.1-
060 are provided as Additional file 1. The methodologies
for synthesis of CXP14.1-034, RR2, RR6, RR7, RR8 and
SN12,601 have been previously published in Jansen *et al.*
[13]. N5-Pan and N7-Pan were synthesized as described
in the supplemental material of Jansen *et al.* [14]. N9-
Pan was synthesized as N5-Pan and N7-Pan, but instead
of using a pentylamine or heptylamine, a nonylamine
was used for the synthesis of N9-Pan. The synthesis of
SN14,621 and SN14,622 was performed as described in
Winterbottom *et al.* [19]. The synthesis of phenethyl-
Pan was performed as described by Spry *et al.* [9].

Chemical structures for all of the compounds in this
study are presented in Figure 1.

**Plasmodium falciparum culture**

The asexual stages of the NF54 strain *P. falciparum* were
cultured as previously described [6], utilizing a shaker
system with automated media change twice a day, parasites
were kept in continuous culture within adapted Erlen-
meyer flasks [20]. Erythrocytes were refreshed every two or
three days to adjust haematocrit to 5% and parasitaemia to
0.5%. Human erythrocytes (blood type A) were obtained
from healthy blood donors, with no history of malaria.
Culture media consisted of RPMI 1640 with HEPES
[5.94 g/l, hypoxanthine [0.05 g/l], 10% (v/v) pooled human
serum (blood type A) obtained similarly to erythrocytes,
and 0.2% (w/v) sodium bicarbonate. Temperature was set
to 37°C and a low oxygen gas mixture was constantly
flushed over the culture maintaining a stable atmosphere
of 3% O2, 4% CO2 and 93% N2.

**Vanin activity assay**

Vanin/pantetheinase activity assay with aminomethyl-
coumarine (AMC) substrate and fluorescence readout
was performed as described previously in Jansen *et al.*
[13,21]. Human serum was used as a source of vanin
enzymatic activity in assays to determine the anti-vanin
activity of study compounds CJ-15,801, SN 12,601, SN
14,621, SN 14,622, CXP14.1-034, CXP14.1-060, RR2, RR6,
RR7, and RR8. To determine whether *P. falciparum* para-
sites harbour vanin activity, assays were performed on para-
site extracts. To this end, 5 to 9 x 10^6 non-synchronous
sexual NF54 strain *P. falciparum* parasites were pelleted
by centrifugation at 4000 rpm for 10 minutes. Pellets were
re-suspended in 5 ml of 0.06% saponin in phosphate buff-
ere salme (PBS) and incubated on ice for 5 minutes to re-
move erythrocytes. After this they were washed with PBS
twice, with centrifugation in between as when pelleting
cultures. Pellets from four different cultures were
individually resuspended in a total volume of 300 μl of
PBS and lysed by sonication (6 x 3 seconds). Vanin
activity was determined by combining 29 μl of lysate with
1 μl of AMC substrate (final concentration of 333 μM)
and incubation at room temperature. At 0, 1 and
19 hours, 3 μl of the reaction was diluted with 997 μl of
PBS and fluorescence was measured in a 200 μl aliquot.
Assay negative controls consisted of 29 μl of PBS and
1 μl of AMC substrate. Positive control consisted of
19 μl of PBS, 10 μl of human serum, and 1 μl of AMC
substrate.

**Plasmodium falciparum asexual blood stages assay with
SYBR Green read-out**

A non-synchronous asexual NF54 strain *P. falciparum*
culture was adjusted to a parasitaemia of 0.5-1% and a
haematocrit of 1-5%. The compound dilution curves were prepared in dimethylsulphoxide (DMSO) from 100 mM to 10 μM at half/log step dilutions. The established anti-malarial dihydroartemisinin (DHA) was used as a positive control and diluted in DMSO from 1 mM to 100 nM at half/log step dilutions. The DMSO dilutions were 500-fold diluted in growth medium to yield a final DMSO concentration of 0.2% (v/v), and final compound concentrations from 200 μM to 0.1 μM for DHA. Higher concentrations for the experimental compounds would not have been possible to achieve due to limitations in final DMSO concentration (0.1% v/v). Fifty μl of each compound dilution was combined with 50 μl of parasite culture in a black, clear-bottomed or entirely black 96-well plate. The outermost wells were filled with sterile water to prevent evaporation. DHA at a concentration of 1 μM and 0.1% DMSO (negative control) were used to determine the assay window. The 96-well plates were incubated for 72 hours in a candle jar at 37°C. Read-out was done using the DNA-marker SYBR Green as described previously [22,23]. All assays were conducted at least in triplicate.

When combining two compounds in the same well the conditions were otherwise similar to the single compound assays, however the final DMSO concentration was 0.2%, which was also adjusted for the positive and negative controls and was not found to cause differences in results obtained with single compounds in assay containing 0.1% DMSO. The pantothenamide phenethyl-Pan was combined with a 10^{-7} to 10^{-5} M concentration curve of CXP14.1-060; the other pantothenamides were combined only with a 5 μM concentration of the same vanin inhibitor. The pantothenone vanin inhibitor RR8 was additionally combined with 20 μM, 6.3 μM, 2.0 μM, and 0.6 μM of pantothenate to explore potential competition for the same molecular target in *P. falciparum*. All assays were conducted at least in triplicate.

### Statistical analyses

Statistical analyses were performed using GraphPad Prism 5. This includes producing inhibition curves, normalizing them to percentage of inhibition, calculation of IC_{50} values, correlation coefficients (Spearman non-parametric correlation), and Schild analyses [24]. The IC_{50} is the concentration of the compound in question at which the compound reaches 50% inhibition relative to the DHA control curve, and is calculated using the interpolate function in GraphPad Prism 5.
Results

Anti-malarial activity of pantothenamides

Using *P. falciparum* cultured in 10% human serum, the low level of anti-malarial activity of the pantothenamides N5-Pan, N7-Pan and phenethyl-Pan was confirmed, as shown in Figure 2A. None of these pantothenamides showed an IC$_{50}$ below 50 μM. In addition, N9-Pan was tested. N9-Pan is a pantothenamide that has previously been shown to have modest antibacterial activity but had not been investigated for its anti-malarial activity [8]. N9-Pan was found to be clearly more potent than the other pantothenamides, with an IC$_{50}$ of about 15 μM, in the presence of serum (Figure 2A). To investigate the effect of vanin inhibition on the potency of the pantothenamides N5-Pan, N7-Pan and N9-Pan, these were combined with 5 μM of the newly synthesized vanin inhibitor CXP14.1-060, that has nanomolar potency against human vanins, yet no anti-malarial activity up to the highest concentration tested (100 μM) (Table 1). The potency of N5-Pan and N7-Pan increased upon vanin inhibition, but the effect was not as great as with phenethyl-Pan (Figure 2B). Remarkably, the potency of N9-Pan was not increased by the addition of the vanin inhibitor (Figure 2B). The potency of DHA did not change upon addition of 5 μM of the vanin inhibitor CXP14.1-060 (Figure 2C).

Phenethyl-Pan was selected to further investigate the protective effect of the synthetic vanin inhibitor CXP14.1-060 on its anti-malarial activity. Phenethyl-Pan was previously shown to have an IC$_{50}$ of 20 nM in ‘aged’ medium and is the most potent anti-malarial pantothenamide known so far [9]. A dose range of this compound was tested in the presence of varying concentrations of CXP14.1-060 (Figure 3). The potency of phenethyl-Pan visibly improved upon addition of increasing concentrations of CXP14.1-060, reaching an IC$_{50}$ of 23 nM (95% CI: 16.5-31.9 nM) upon addition of 10 μM of CXP14.1-060 (Figure 3). In the presence of 10 μM of vanin inhibitor CXP14.1-060, phenethyl-Pan showed a full inhibition of parasite growth, comparable to the efficacy of DHA, which was used as a reference compound and has an IC$_{50}$ in the low nanomolar range. This experiment shows that small molecule inhibition of pantothenamide hydrolysis will allow the same level of protection found in heat-inactivated medium as shown by the comparable IC$_{50}$ values [10].

*Anti-vanin activity tested in human serum. NA: Not Applicable. NT: Not Tested.*
Anti-malarial activity of pantothenones

15 pantothenate derivatives were synthesized and assayed for anti-malarial activity in the presence of 10% human serum. The structures of these compounds are presented in Figure 1, and their observed individual biological effects are presented in Table 1. Some of the newly synthesized vanin inhibitors were structurally similar to pantothenate derivatives described in the 1940s, which were shown to have anti-malarial activity in avian malaria models [2]. Some of these reference compounds were re-synthesized, including the pantothenone SN12,601 and the sulphonamides SN 14,621 and SN 14,622. In this study, they were found to have moderate activity, and the effect of their dilution curves on \( P. falciparum \) growth are shown in Figure 4. In addition, pantothene and CJ-15,801, two natural compounds with known weak activity against \( P. falciparum \), were also tested [18,25]. CJ-15,801 was found to be a poor inhibitor of \( P. falciparum \) growth (Table 1 and Figure 4) and pantothene showed no anti-malarial activity up to the highest concentration tested (100 \( \mu \)M) (Table 1). Out of the newly synthesized pantothenes, the vanin inhibitor RR8 was the most potent of these compounds, having an IC\(_{50}\) value of 2.2 \( \mu \)M (95% CI: 1.6-3.1 \( \mu \)M) (Table 1 and Figure 4).

Mechanism of anti-malarial activity of pantothenones

It was considered, that the pantetheinase inhibiting activity of the new compounds may contribute to anti-malarial activity. Therefore, the IC\(_{50}\) values of \textit{in vitro} inhibition of asexual blood stages of \( P. falciparum \) were plotted against the IC\(_{50}\) values of anti-vanin activity in human serum (Figure 5). There was no correlation between these activities, suggesting that pantetheinase inhibition is not the mode of action of the small molecule inhibitors in \( P. falciparum \) asexual blood stages. In line with this finding, an assay using the AMC substrate to detect pantetheinase activity, did not detect hydrolytic activity in extracts of purified asexual stages of \( P. falciparum \), even after a 19 h incubation period, suggesting that the parasite lacks such enzyme activity (Figure 6). This notion was corroborated by a BLAST search that did not reveal sequences in the \( P. falciparum \) genome database with homology to mammalian vanin genes. In order to investigate an alternate mode of action, competition experiments with pantothene were performed. To this end, a \( P. falciparum \) asexual blood stage growth assay was performed with eight concentrations of RR8 combined with eight concentrations of pantothene. An increase in the IC\(_{50}\) of RR8 was found to occur at addition of increasing concentrations of pantothene (Figure 7A). Upon performing a Schild analysis on the results of the concentrations, 20 \( \mu \)M, 6.3 \( \mu \)M, 2.0 \( \mu \)M, and 0.6 \( \mu \)M of pantothene in combination with a dilution curve of RR8, the slope of the line in the Schild Plot was 1.087 ± 0.089, indicating that RR8 and pantothene are competing for the same target in \( P. falciparum \) (Figure 7B).

Discussion

This study underscores the potential of pantothenate derivatives for anti-malarial therapy, and demonstrates that the most potent serum-labile anti-malarial pantothenamide (phenethyl-Pan) can be effectively protected against hydrolysis by serum pantetheinases using the novel vanin inhibitor CXP14.1-060. From a mechanistic point of view, this study indicates that the pantothenone RR8

![Figure 3](image_url) Anti-malarial activity of phenetyl-Pan in the presence of varying concentrations of vanin inhibitor CXP14.1-060. Combination of anti-malarial pantothamide phenetyl-Pan [9] with novel vanin inhibitor CXP14.1-060. Filled upright triangles represent phenetyl-Pan, with CXP14.1-060 added at a different concentration for every curve as indicated in figure. At a concentration of 10 \( \mu \)M of CXP14.1-060 phenetyl-Pan has an IC\(_{50}\) of 23 nM (95% CI: 16.5-31.9 nM).
exerts its anti-malarial effect through competition with pantothenate.

In the 1940s, a number of chemical variations on pantothenate were synthesized and tested for anti-malarial activity [2]. These included pantothenones and sulphonamides, which were found to be active against avian malaria. This study shows that these compounds are also active against the human parasite *P. falciparum*.

Although the new vanin inhibitor CXP14.1-060 effectively protected phenethyl-Pan, such a combination of drugs would be undesirable from a drug development perspective. Clearly, the potency and/or stability of pantothenate derivatives needs to be improved before they can enter a drug development programme as therapeutic agents for human malaria infection. Nevertheless, the recent discovery of phenethyl-Pan with an *IC*$_{50}$ of 20 nM is encouraging [9]. Although this compound is unstable in plasma, it illustrates that it is realistic and feasible to aim for pantothenate derivatives active in the low nanomolar range. The study by de Villiers *et al.* showed that structural modifications of pantothenamides can be introduced to confer resistance to plasma-mediated breakdown [10]. These novel compounds, although less potent than the original pantothenamides, are a starting point for further lead optimization studies [10]. Optimization of the potency would be important to maximize the risk-benefit of a novel drug, as side effects may be mediated by low-affinity, off-target effects. In addition, increasing the potency may lead to a lower effective dose in humans, and hence impact the cost of treatment. Availability of affordable medicines is an important driver for success in malaria control, and the goal for development of novel drug therapies is to achieve effective treatment with a total cost of US$1 [26]. In that respect, the molecules described here provide attractive candidates as their chemistry is simple, which ensures a low cost of goods in a manufacturing process.

Many of the marketed anti-malarials and compounds in the clinical development portfolio originate from whole

![Figure 4](image-url) Anti-malarial activity of pantothenones and reference compounds. Inhibition curves for all compounds with *IC*$_{50}$ values below 100 μM, and CJ-15,801, against asexual blood stages of *P. falciparum* in a proliferation assay with a SYBR Green read-out.
cell phenotypic screening efforts and exert their actions by inhibiting multiple targets or pathways of the parasite. Although such a polypharmacological profile may be important to their efficacy, it is an undesirable feature in a rational medicinal chemistry approach. The exact target of the anti-malarial pantothenate derivatives has not been identified unequivocally but is likely that they exert their effects by affecting targets dependent on pantothenate. In theory, the observed effects could still be mediated by effects on red blood cell biology (e.g., red blood cell pantothenate kinases (PANK)) rather than directly on the parasite. However, the recent discovery of a parasite-specific pantothenate transporter [27] leaves very little doubt that the parasite itself is the target of interfering with pantothenate dependent pathways. Future drug development efforts would benefit from information on the molecular targets of pantothenamides, which would include both biosynthetic pathways (CoA synthesis, lipid synthesis, energy metabolism) and pantothenate transport systems. Structural information, which is available for mammalian and bacterial PANK, could guide medicinal chemistry strategies to achieve specific inhibition of the parasite enzyme and reduce side effects on the host.

Conclusions
Pantothenamides with anti-malarial activity can be protected from breakdown by ubiquitous pantetheinases of the vanin family with small molecule pantetheonone vanin inhibitors. Some of these pantetheonones exhibit anti-malarial activity in their own right. Compound series such as the one tested in this publication should be studied further for use as lead compounds for anti-malarial treatment.

Additional file 1: Supplemental Materials and Methods. The supplemental materials and methods explain how the compounds CJ-15,801 and CXP14.1-060 were synthesized.
Abbreviations
CoA: Coenzyme A; DHA: Dihydroartemisinin; DMSO: Dimethylsulphoxide; PA: Pantothenic acid, pantothenate, vitamin B5; PanK: Pantothenate kinase (Plasmodium falciparum); PANK: Pantothenate kinase (Nomo sapiens).

Competing interests
KD and RS hold shares in TropIQ Health Sciences, a spin-off company of the RadboudUMC that aims to develop anti-malarial drugs. JS, FPJTR and PHHH hold shares in Pansynt, a spin-off company of the RadboudUMC that aims to develop pantothenate-based drugs for infectious diseases. Some of the compounds described in the manuscript are covered by a patent application (PCT/ NL2011/050385) filed by the RadboudUMC (inventors: PAMJ, JS, RS, PHHH, FPJTR).

Authors’ contributions
HEP carried out the majority of P. falciparum proliferation assays and the majority of the writing of the manuscript. PAMJ carried out the vanin inhibition assays and wrote some of the manuscript. PHHH is responsible for design of active compounds and for writing of the supplemental material of the manuscript. PHNB and CABS synthesized active compounds, RHB was responsible for conception of chemical synthesis routes. WG and MV-8 worked on early experimentation with compounds. KMJK performed the experiment that resulted in Figure 2C. FPJTR is responsible for design of active compounds. KD supervised experimental work of HEP and wrote a substantial part of the discussion section. RS approved work being done during experimental process. JS initiated the project, supervised experimental work of HEP and PAMJ, and wrote a substantial part of this publication. All authors have read and approved final version of the manuscript.

Submit your next manuscript to BioMed Central and take full advantage of:

- Convenient online submission
- Thorough peer review
- No space constraints or color figure charges
- Immediate publication on acceptance
- Inclusion in PubMed, CAS, Scopus and Google Scholar
- Research which is freely available for redistribution

Submit your manuscript at www.biomedcentral.com/submit
