The aim of this paper is to identify and investigate an endophytic fungus (strain 28) that was isolated from Houttuynia cordata Thunb, a famous and widely-used Traditional Chinese Medicine. Based on morphological methods and a phylogenetic analysis of ITS sequences, this strain was identified as Chaetomium globosum. An antifungal activity bioassay demonstrated that the crude ethyl acetate (EtOAc) extracts of strain 28 had a wide antifungal spectrum and strong antimicrobial activity, particularly against Exserohilum turcicum (Pass.) Leonard et Suggs, Botrytis cinerea persoon and Botrytis cinerea Pers. ex Fr. Furthermore, the fermentation conditions, extraction method and the heat stability of antifungal substances from strain 28 were also studied. The results showed that optimal antifungal activity can be obtained with the following parameters: using potato dextrose broth (PDB) as the base culture medium, fermentation for 4–8 d (initial pH 7.5), followed by extraction with EtOAc. The extract was stable at temperatures up to 80 °C. This is the first report on the isolation of endophytic C. globosum from H. cordata to identify potential alternative biocontrol agents that could provide new opportunities for practical applications involving H. cordata.

Introduction

Endophytic fungi are considered as novel sources for bioactive compounds that have important applications in the fields of agriculture and medicine. These fungi may possess the potential to produce bioactive compounds, and this potential to produce bioactive compounds is equal or similar to that of their host.¹ ² Studies have shown positive symbiosis between endophytic fungi and their hosts. For example, the secondary metabolites of endophytic fungi can facilitate the growth of their host plants directly or indirectly and improve host resistance to abiotic or biotic stresses.³ Substantial renewed attention is now being paid to endophytic fungi, which have inhibitory activity toward pathogenic fungi⁴ and play an indispensable role in fungal biocontrol.⁵ Recently, an endophytic fungal strain was isolated by Santiago et al.⁶ from the Cin namomum mollisimum plant. One bioactivity of a metabolite

from this plant, which was identified as a polyketaide, was the efficient killing of the fungal pathogen Aspergillus niger (IC_{50} 1.56 μg mL^{-1}).

Conventional chemical fungicides have been shown to be harmful to the environment and to public health, and they can cause pathogens to become resistant when used for a long time. By contrast, extracts from natural products showed advantages with regards to environmental protection and human health. For example, Yin et al. suggested that an ethyl acetate (EtOAc) extract of Trichoderma harzianum fermented broth can control the tomato gray mold caused by Botrytis cinerea, without fungicide resistance and in an environmentally friendly manner. In addition, secondary metabolites have been a continuous source of new lead compounds and chemical entities in the fields of agriculture and medicine. For instance, multiple fungal metabolites, such as 12β-hydroxy-13α-methoxyverrucologen TR-2, fumitremorgin B, verruculogen, and helvolic acid and others from an endophytic fungus (strain Aspergillus fumigatus LN-4) exhibited high antifungal activities against multifarious phytopathogenic fungi.

Houttuynia cordata Thunb. is a significant plant resource to screen for endophytic fungi that could produce specific metabolic products for use as biofungicides. In fact, a great number of medicinal plants have been used in China to cure various diseases for a long time, and abundant plant use experience has been accumulated. In Traditional Chinese Medicine (TCM), H. cordata has been used to cure inflammation, bronchitis infections of the upper respiratory cavity, coughs, arthritis, conjunctivitis and infections of the urethral channel because of its antifungal, antiviral, anti-mutagenic, anti-oxidative, and antileukemic activities and for its immunity-increasing effects. Nevertheless, little published work has focused on testing endophytic fungi from H. cordata. Consequently, our group is interested in these fungi and in particular in those with antifungal activity.

Based on metabolic studies about using endophytic fungi as biofungicides, we isolated an endophytic fungal strain from fresh, symptomless H. cordata tissues that were collected from Sichuan province, southwest China. We primarily investigated their antifungal activity and best processing parameters to lay a foundation for the further use of effective biocontrol agents.

Materials and methods

Isolation of the endophytic fungus

Source organism: The endophytic fungus (strain 28) was isolated from fresh, intact H. cordata, which was collected from Yaan City, southwest China and identified by Professor Wu Wei. The above site has a subtropical humid monsoon climate with abundant rainfall. Strain 28 was then stored in a refrigerator at 4°C.

The isolation procedure was based on the article with minor modifications: Healthy samples were collected in plastic bags and placed in an icebox at once, and then they were transported to the laboratory within a maximum of 48 h. The sample surfaces were washed with running water to remove soil and then sterilized as follows: the samples were rinsed with sterile distilled water 3 times; they were submerged in 75% ethanol for 1 min and rinsed 5 times with sterile water, followed by 0.1% HgCl₂ for 1 min; and lastly, they were rinsed with sterile distilled water 5 more times. The sample surfaces were dried with sterile blotting paper. The surface-sterilized tubers were cut into 0.5 cm-long segments, and the center of the sterilized leaves was cut into 10 mm x 10 mm pieces with sterile blades. The tissues (4 segments or pieces per plate) were placed on potato dextrose agar (PDA) medium (containing more than 30 μg mL⁻¹ streptomycin and ampicillin) and incubated at 28°C in the dark for 5–7 d. Three replicate plates were used for each test. The colonies were examined periodically, and the endophytic fungal hyphae that emerged from the segments were transferred onto fresh PDA medium. Transfers were not repeated until a pure culture was obtained according to the colony morphology. To validate the effect of surface disinfection, uncut tissues that were sterilized according to the same steps were placed on PDA medium and incubated under the same conditions as the control. In addition, the last drift lotion from the surface-sterilization process (1–2 drops) was added to the PDA culture medium and coated evenly as another control. Finally, we examined the effect of disinfection after checking whether colonies had formed.

Morphological characterization

Strain 28 was incubated on PDA medium at 28°C for 7 d. A morphological characterization was then used to identify the strain using a combination of the fungal characteristics in parallel with those in the literature including the mycelia, sporangium, and spore morphology as well as the external form of the colony.

Molecular identification, ITS sequence analysis

After a strain 28 subculture was grown in an Erlenmeyer flask (250 mL) containing 150 mL of potato dextrose broth (PDB) (200 g L⁻¹ potato and 20 g L⁻¹ dextrose, initial pH 6.6–7.0) at 130 revolutions per minute (rev min⁻¹) for 7 d at 26°C, the mycelia and broth were separated by vacuum suction filtration. The mycelia were then scraped from the filter and ground into powder with the aid of liquid nitrogen. Genomic DNA was extracted by CTAB method. The quality and integrity of the DNA were estimated by electrophoresis on a 1% (w/v) agarose gel. The ITS1-5.8S rRNA-ITS2 region, which was the target rDNA region, was amplified using primers ITS1 (5′-TCCTTGGGATTCACGCGG-3′) and ITS4 (5′-TCCTTGGTATTGATATGC-3′). Each 25 μL reaction contained 2.5 mM 10× buffer (with Mg²⁺), 2.0 mM (10 μmol L⁻¹) dNTPs, 2.0 mM (5 μmol L⁻¹) of each primer, 1.0 mM (3 U) Taq DNA polymerase, and 1 mM genomic DNA. Polymerase chain reaction (PCR) amplifications were performed in a thermal cycler (ABI2720, USA) with an initial denaturing step at 94°C for 5 min, followed by 35 amplification cycles of 94°C for 30 s, 60°C for 30 s, 72°C for 60 s and a final extension step of 72°C for 10 min. The amplification products were separated by electrophoresis on a 1% (w/v) agarose gel at 100 V for 30 min in 1× TAE buffer and stained with ethidium bromide (0.5 μg mL⁻¹). The purified PCR product was then sent
to Shanghai Sangon Biological Engineering Technology & Services Co. Ltd. for sequencing. The sequence was submitted to the National Centre for Biotechnology Information (NCBI) GenBank and analyzed by BLAST.

Culture conditions during fermentation

Strain 28 was stored in the refrigerator, and then it was incubated on FDA medium at 28 ºC for 6–7 d. A fungus plug (4 mm diameter) of mycelial inoculum was cut from the margin of actively growing strain 28 colonies and transferred into an Erlenmeyer flask (250 mL) containing 150 mL of fermentation medium (4 plugs per flask). Under base culture conditions, the strains were incubated in PDB at 26 ºC for 7 d and initial pH value of 6.6–7.0. The rotation rate of the incubator was fixed at 130 rev min⁻¹. The culture conditions were varied on the basis of the experimental design.

Metabolite extraction

Fungal mycelia were separated from the culture broth by vacuum filtration and discarded after the fermentation procedures. The filtrate was collected and concentrated as least as 10% of the original volume (v/v) in a vacuum rotary evaporator at 40–45 ºC, then extracted three times at the liquid-liquid partition with EtOAc solvent 1:1 (v/v). The resulting crude extracts were collected and concentrated to dryness in a vacuum rotary evaporator at 45–45 ºC, then dissolved into 3 mL of acetone per 150 mL of initial culture volume, followed by filtration through 0.22 μm Millipore filters to obtain the EtOAc-extracted solution.

Antifungal activity bioassay

The antifungal activity of the crude metabolites was determined by mycelial growth methods against the following 15 species of plant pathogens: Fusarium graminearum Seh. (B1 for short), Alternaria solani (Ell. et Mart.) Sorauer (B2), Phytophthora capsici Leonian (B3), Fusarium oxysporum f. sp. niveum (B4), Sclerotinia sclerotiorum (Lib.) de Bary (B5), Exserohilum turcicum (Pass.) Leonard et Suggs (B6), Aphanomyces raphani Kendrick (B7), Puccinia zoysiae Diet. (B8), Fusarium moniliforme Sheld. (B9), Alternaria alternata (Fries) Keissler (B10), Botrytis cinerea Persoon (B11), Alternaria solani Sorauer (B12), Thielaviopsis basicola (Berk. et Br.) Ferrariz (B13), Botrytis cinerea Pers. ex Fr. (B14), and Bipolaris maydis (Nisikado et Miyake) Shoeml (B15). All the pathogens above were provided by the laboratory of phytopathology at Sichuan Agricultural University, China. The pathogens were activated from dormant states. After that, the fungus plugs (4 mm diameter) of 15 pathogenic fungi (B1–B15) from the margin of actively growing colonies were placed in the center of PDA medium plates containing 10% of the EtOAc-extracted solution (v/v). In addition, extract-free acetone (10% in medium) was used as a control. The experiments were performed in triplicate for each pathogenic fungus and control. Those plates then were incubated in the dark for 7 d, and the colony diameter was measured in two perpendicular directions.

Optimization of process parameters

To screen for the best processing parameters, the effects of the culture and the ferment disposal conditions on antifungal crude extract production were investigated using single-factor experiments. The inhibitory rate of the crude strain 28 extracts against B4 served as the indicator of antifungal activity. The base culture conditions and the crude extraction of the metabolites were completed according to the above method. Extract-free acetone was used as a negative control. All experiments were performed in triplicate.

Media Optimization: Strain 28 was inoculated into eight different liquid media (Gause No. 1 liquid medium, Czapek-Dox broth, Sabouraud’s dextrose broth, BSE (0.5% succinate, 0.04% K₂HPO₄, 0.04% KH₂PO₄, 0.02% MgSO₄ · 7H₂O, 0.05% yeast extract; pH 6.5), Martin’s broth, LB broth, medium A, and PDB) to select a suitable medium.

Initial pH test: Strain 28 was inoculated onto different PDB basic media at different initial pH values (initial pH values of 6.0, 6.3, 6.6, 6.9, 7.2 and 7.5).

Incubation time test: Ten conical flasks (250 mL), each of which contained 150 mL of the PDB basic medium, were incubated for 3, 4, 5, 6, 7, 8, 9, 10, 11 and 12 d.

Thermal stability of antifungal activity assay: Seven uniform-bore glass tubes with fine gradations were numbered as control keeping (CK) and 1–6. Three milliliters of the extraction solution was poured into the flasks, which were then heated in a water bath for 30 min at temperatures of 40 ºC, 50 ºC, 60 ºC, 70 ºC, 80 ºC, 90 ºC, and 100 ºC, respectively.

Antifungal compound extraction: To investigate the effect of the extraction solvent on the fermentation broth, 5 different extraction solvents (petroleum ether, diethyl ether, n-butyl alcohol, EtOAc and alcohol) were chosen to extract the antifungal compounds.

Antifungal activity assay: We prepared enough 50-mL Erlenmeyer flasks so that each contained precisely 30 mL of PDB medium [including 10% of the extracted solution (v/v)] for each process parameter above. Next, this 30 mL mixture was poured into three Petri dishes per condition. A fungus plug (4 mm diameter) of mycelial inoculum was cut from the margin of actively growing B4 colonies as an indicator fungus, and it was placed in the center of the PDA medium of each dish. Having been inoculated, these dishes were wrapped with plastic wrap (which was purchased in the supermarket), and incubated in an incubator at 28 ºC for 7 d. Finally, the suppression of B4 by fermented broth extract was measured in two perpendicular directions using a growth rate method.

Statistical analysis

The inhibitory rate of the crude strain 28 extracts against each fungus was calculated by using the following formula: antifungal rate = [(average colony diameter of control – average colony diameter of treatment)/average colony diameter of control] × 100 %. The colony diameter was measured in two perpendicular directions as described above.

All the results were expressed as the average ± standard deviation of triplicate determinations. An analysis of statistical significance was performed according to the one-way
Fig. 1 – The colony and microstructure of strain 28: colony front sides (A), colony back sides (B), ascocarps (C) and spore morphology (D). The colonial morphology was observed after growing on a PDA plate at 28 °C for 6 d, and the microstructure of the strain was observed under an Olympus BX 51 fluorescence microscope (OLYMPUS OPTICAL.CO.LTD. Tokyo, Japan) after growing for 7 d.

Results and discussion

The strain 28 colonies (which grew on PDA plates at 28 °C for 6 d) were similarly flattened, black-gray, white and lobed on the edge, and they grew relatively slowly (Fig. 1A). The reverse sides of the colonies were dark yellow to auroantium (Fig. 1B), and the ascocarps were olive or green-yellow with ascomal hairs (Fig. 1C). Moreover, the spores were pale brown and lemon-shaped (Fig. 1D). Therefore, these characteristics corresponded well with those of Chaetomium globosum.15

The amplified ITS1-5.8S rDNA-ITS2 region of the selected isolates (GenBank accession number: KF697163) was sequenced and compared with the ITS sequences of organisms represented in the NCBI GenBank database by using a BLAST search and DNAMAN to generate a phylogenetic tree (Fig. 2) by Neighbor-joining method. The sequences that showed E = 0.0 and the highest % similarity with the amplified sequences were included for alignment and bootstrapping using CLUSTALX. The phylogenetic relation of this isolate to related fungi is shown in Fig. 2. Thus, this strain was identified as C. globosum of Chaetomium sp. based on its morphological characteristics and the rDNA sequencing of its region data. Chaetomium sp. is cosmopolitan in distribution and it represents a considerable microorganismal resource.21

The results in Table 1 show that the crude EtOAc extracts of strain 28 could effectively inhibit 15 types of pathogenic fungi, especially B6, B11 and B14, the inhibition ratios of which were all 100.00% as well as B15 and B7 at 91.67 ± 0.24% and 86.18 ± 4.28%, respectively (Fig. 3). On the whole, the inhibition ratios for all the pathogenic fungi were above 50%, except for B13 and B12, which had inhibition ratios of 41.67 ± 1.27% and 45.93 ± 1.74%, respectively. This result shows that the crude extracts of strain 28 have broad-spectrum antifungal abilities. In 1954, Tveit22 suggested that C. globosum could control the wheat seedling blight caused by Helminthosporium victoriae. Abundant new reports have indicated that Chaetomium are interesting microbial antagonists that are used to control phytopathogens. There have been more than 200 compounds reported from this genus to date.21 Many of them are endophytic fungi from plants. Endophytic Chaetomium was reported to be antagonistic to the development of disease in wheat leaves caused by Pyrenophora tritici-repentis.23 A gliotoxin isolated from endophytic C. globosum that originated from Ginkgo biloba showed good antifungal activity against Fusarium graminearum.24 A novel cytotoxic agent that was derived from chlorinated azaphilone and named chaetomugilin was
isolated from the cultures of C. globosum that originated from Ginkgo biloba. C. globosum EP18 endophytic fungus extract originating from Withania somnifera is reported to be significantly effective against Sclerotinia sclerotiorum.

From a genetic standpoint, plant endophytic fungi are able to synthesize bioactive compounds that are equal or similar to those synthesized by their hosts, possibly as a result of horizontal gene transfer between endophytic fungi and their corresponding hosts. Furthermore, C. globosum is able to degrade lignin, which is beneficial to horizontal gene transfer. Other work has shown that a recombinant plasmid containing the TUB2-resistance gene conferred 300 times higher resistance to carbendazim when transformed into a Chaetomium sp. protoplast using the PEG method. However, H. cordata shows potent antifungal activities as a TCM over a long period. Therefore, strain 28 might display effective antifungal properties as a result of horizontal gene transfer with its host.

Plant pathogens are harmful to the development of crops, and thus there have been many attempts to control them. However, abundant novel pathways or substances with efficient and environmentally friendly characteristics require further research because of the high-frequency heritable

---

variation of pathogens with biotope changes and demands in agricultural development. Furthermore, endophytic fungi are becoming interesting sources of bioactive compounds including antifungals. Our work has shown that the crude EtOAc extracts of strain 28 were broad-spectrum and efficient in terms of their antifungal ability. Therefore, it is promising and interesting to study this fungus further and develop its utility value as a biocontrol agent.

We also discuss the optimization of process parameters using single-factor experiments. A large amount of endophytic fungal metabolites are obtained principally by means of liquid fermentation, in which culture conditions play a crucial role. Three variables (culture medium, initial pH and fermentation time) that significantly influence fungal growth were selected as the key culture condition factors prior to optimization.

Culture medium directly affects the biosynthesis and accumulation of secondary metabolites because it supplies nutrients and serves as a spatial carrier during the fermentation process. Table 2 indicates that there were significant differences ($p<0.05$) among several culture media. Martin's broth displayed the most obvious ability to contribute to the accumulation of antifungal substances during strain 28 growths, and it possessed the maximum inhibition ratio (82.53% ± 1.95%) ($p<0.05$).

The initial pH is widely recognized as a critical factor in fermentation because it can affect individual physiological phenomena, such as fungal growth, sporulation, and the production of enzymes, and it can influence enzyme stability. Therefore, research is needed to determine the optimal initial pH. The range of initial experimental pH values given here was based on preliminary tests. The results show obvious significant differences ($p<0.05$) from pH 6.0–pH 7.5, and pH value of 6.9 is the most beneficial for the accumulation of antifungal substances and results in the highest inhibition ratio of 81.69% ± 1.81% (Table 3) in spite of showing no significant difference ($p<0.05$) from that of pH 6.0–6.9.

The inhibition ratio increased substantially ($p<0.05$) from 3 d to 4 d of fermentation time, and then there was no significant difference from 4 d to 8 d, immediately followed by a significant decrease ($p<0.05$) with an increase in the fermentation time (Table 4). Secondary metabolites (such as antibiotics) begin to be produced near the onset of the stationary growth phase of a microbial growth curve, where the specific growth rate is zero. Therefore, the species and content of antifungal substances increased with increased fermentation time. Eventually, however, more and more fungal cell death occurred, usually because the cells burst open, which is also known as cell lysis, and this lysis resulted

* Each value is the average ± standard deviation of triplicate determinations.
* Values with the same letter are not significantly different ($p<0.05$) according to the one-way analysis of variance (ANOVA).
in reduced inhibition ratios after more than 8 d. To save

Time without compromising on the content of antifungal

Substance, 4 d of fermentation was chosen as a suitable time.

Temperature treatments of the crude extracts over the

Course of concentration and solvent extraction is also critical

Apart from the culture conditions because some compounds

Are temperature-sensitive or have different solubilities at dif-

Fermentation, therefore, the conditions of fermentation

Disposal were optimized.

The thermal stability of extracts from fermentation broth

Should be investigated as much as possible to prevent ther-

al degradation. We tested the thermal stability of the

Extracts in a water bath at different temperatures. Table 5

Lists the changes in antifungal activity against the indicator

Pathogen (B4) after the EtOAc extracted solution was heated

for 30 min at temperatures of 40 °C, 50 °C, 60 °C, 70 °C, 80 °C,

90 °C, and 100 °C. The antimicrobial activity of the EtOAc

Extracting solution varied from 0.00 ± 0.00% to 55.12 ± 0.35%.

There were significant differences (p < 0.05) above 70 °C, and

The inhibition ratio decreased rapidly to 0 at 100 °C. Clearly,

This result indicates that the antimicrobial substances from

Strain 28 were heat-stable after thermal treatment up to 80 °C.

The antimicrobial activities of the extracts that were treated

At temperatures higher than 80 °C declined sharply, possibly

Because of thermal degradation. It is notable that Zhao et al.36

Drew a similar conclusion when the antibacterial metabolites

Of a marine fungus (NJ1004) were thermally stable up to 80 °C.

Hence, there is a justification in that part of the antibacterial

Metabolites can maintain biological activity at least at marine

Temperatures.

Bioactive antifungal compounds are extracted efficiently

Only by suitable extraction solvents because of their differ-

ent polarity and solubility properties. There were significant
differences (p < 0.05) among five extraction solvents (Table 6).

EtOAc extract exhibited the strongest antifungal ability fol-

owed by diethyl ether and n-butyl alcohol extracts.

On a more general note, there is also a need for further

Study on how to use secondary metabolites from strain 28

As biocontrol agents. For example, there is a lack of stud-

Ies on direct antifungal effects in crops, and phytopathogenic

Fungus is one of the vital links to developing bio-antifungal

### Table 3 - The inhibition of *Fusarium oxysporum* f. sp. * niveum* by strain 28 when cultivated in liquid medium in vitro at different pH values.

| Initial pH | *Fusarium oxysporum* f. sp. *niveum* |
|------------|--------------------------------------|
|            | Average diameter (cm)* | Inhibition ratio (%)* |
| 6.0        | 2.25 ± 0.28 cd          | 78.92 ± 3.35 ab       |
| 6.3        | 2.40 ± 0.20 cd          | 77.11 ± 2.41 ab       |
| 6.6        | 2.33 ± 0.13 cd          | 77.95 ± 1.52 ab       |
| 6.9        | 2.02 ± 0.16 d           | 81.69 ± 1.81 c        |
| 7.2        | 2.53 ± 0.06 c           | 75.54 ± 0.70 b        |
| 7.5        | 3.05 ± 0.15 b           | 69.28 ± 1.94 a        |
| Control    | 8.80 ± 0.05 a           | 0.00 ± 0.60 d         |

* Each value is the average ± standard deviation of triplicate determinations.
* Values with the same letters are not significantly different (p < 0.05) according to the one-way ANOVA.

### Table 4 - The antifungal ability of strain 28 when cultivated for different times in vitro.

| Days | *Fusarium oxysporum* f. sp. *niveum* |
|------|--------------------------------------|
|      | Average diameter (cm)* | Inhibition ratio (%)* |
| 3    | 8.60 ± 0.17 a            | 2.41 ± 2.09 d         |
| 4    | 3.82 ± 0.08 d            | 60.04 ± 0.92 a        |
| 5    | 3.63 ± 0.12 d            | 62.25 ± 1.39 a        |
| 6    | 3.60 ± 0.10 d            | 62.65 ± 1.20 a        |
| 7    | 3.77 ± 0.06 d            | 60.64 ± 0.70 a        |
| 8    | 3.92 ± 0.18 d            | 58.84 ± 2.12 a        |
| 9    | 4.65 ± 0.09 c            | 50.00 ± 1.04 b        |
| 10   | 4.75 ± 0.05 c            | 48.80 ± 0.60 b        |
| 11   | 5.35 ± 0.13 b            | 41.57 ± 1.59 c        |
| 12   | 5.58 ± 0.16 b            | 38.76 ± 1.94 c        |
| Control | 8.80 ± 0.05 a          | 0.00 ± 0.60 d         |

* Each value is the average ± standard deviation of triplicate determinations.
* Values with the same letter are not significantly different (p < 0.05) according to the one-way ANOVA.

### Table 5 - Inhibition ratio of the antimicrobial substances in strain 28 when treated at different temperatures in vitro.

| Temperature (°C) | *Fusarium oxysporum* f. sp. *niveum* |
|-----------------|--------------------------------------|
|                 | Average diameter (cm)* | Inhibition ratio (%)* |
| 40              | 4.20 ± 0.26 de          | 54.88 ± 3.23 ab       |
| 50              | 4.18 ± 0.03 e           | 55.12 ± 0.35 a        |
| 60              | 4.38 ± 0.18 de          | 52.68 ± 2.14 ab       |
| 70              | 4.58 ± 0.08 cd          | 50.24 ± 0.93 bc       |
| 80              | 4.73 ± 0.08 c           | 48.41 ± 0.93 c        |
| 90              | 7.97 ± 0.15 b           | 8.90 ± 1.86 d         |
| 100             | 8.70 ± 0.00 a           | 0.00 ± 0.00 e         |

* Each value is the average ± standard deviation of triplicate determinations.
* Values with the same letters are not significantly different (p < 0.05) according to the one-way ANOVA.

### Table 6 - Inhibition ratio of the fermentation filtrates from strain 28 when extracted in different solvents in vitro.

| Extraction solvents | *Fusarium oxysporum* f. sp. *niveum* |
|---------------------|--------------------------------------|
|                     | Average diameter (cm)* | Inhibition ratio (%)* |
| Petroleum ether     | 4.22 ± 0.26 b            | 55.18 ± 3.09 d       |
| Diethyl ether       | 2.12 ± 0.06 d            | 80.48 ± 0.70 b       |
| N-butyl alcohol     | 2.20 ± 0.26 cd           | 79.52 ± 3.19 bc      |
| Ethyl acetate       | 1.91 ± 0.02 e            | 83.01 ± 0.28 a       |
| Alcohol             | 2.27 ± 0.06 c            | 78.67 ± 0.70 c       |
| Control             | 8.80 ± 0.05 a            | 0.00 ± 0.60 e        |

* Each value is the average ± standard deviation of triplicate determinations.
* Values with the same letter are not significantly different (p < 0.05) according to the one-way ANOVA.
agents. Previous studies only revealed the antifungal activity of the crude EtOAc extracts in spite of the activity of the single components. However, this investigative direction would lead to fascinating scientific research and practical application value because of the extract’s obvious broad-spectrum antifungal ability. This article is also the first report on the isolation of endophytic C. globosum from H. cordata as a biocontrol agent. Moreover, preliminary data from process parameter optimization assays will provide good guiding significance for harvesting more secondary metabolites from strain 28. In addition, numerous secondary metabolites from multiple C. globosum strains have been reported and showed a variety of biological activities including cytotoxicity, antibacterial activity, phytotoxicity, elicitor activity and others. Therefore, studying this organism and its antifungal compounds further to develop practical applications will be a promising line of research for the future.

Author contributions

FP, ZQL and WW conceived and designed the experiment. ZQL, QC, and YWX participated in sample collection and the isolation of the strain. FP, ZQL and KH analyzed and interpreted the sequence data and identified the strain. In addition, the antifungal activity bioassay and optimization of process parameters including statistical analysis were performed by FP and ZQL. Moreover, FP, ZQL and WW drafted and revised the manuscript. All authors read and approved the final manuscript.

Conflicts of interest

The authors declare no conflicts of interest.
