Received 27 September 2010; revised 5 December 2011; first published online 26 January 2012

Let $k_r(n, \delta)$ be the minimum number of $r$-cliques in graphs with $n$ vertices and minimum degree at least $\delta$. We evaluate $k_r(n, \delta)$ for $\delta \leq 4n/5$ and some other cases. Moreover, we give a construction which we conjecture to give all extremal graphs (subject to certain conditions on $n$, $\delta$ and $r$).

AMS 2010 Mathematics subject classification: 05C35

1. Introduction

Let $f_r(n, e)$ be the minimum number of $r$-cliques in graphs of order $n$ and size $e$. Determining $f_r(n, e)$ has been a long-studied problem. The case $r = 3$, that is, counting triangles, has been studied by various people. Erdős [3], Lovász and Simonovits [7] studied the case when $e = \binom{n}{2} / 2 + l$ with $0 < l \leq n/2$. Fisher [4] considered the situation when $\binom{n}{2} / 2 \leq e \leq 2\binom{n}{2} / 3$, but it was not until nearly twenty years later that a dramatic breakthrough of Razborov [10] established the asymptotic value of $f_3(n, e)$ for a general $e$. The proof of this used the concept of flag algebra developed in [9]. Unfortunately, it seemed difficult to generalize Razborov’s proof even for $f_4(n, e)$. Nikiforov [8] later gave a simple and elegant proof of the asymptotic values of both $f_3(n, e)$ and $f_4(n, e)$ for general $e$. However, the asymptotic value of $f_4(n, e)$ for $r \geq 5$ has not yet been determined, and the best known lower bounds were given by Bollobás [2].

In this paper, we are interested in a variant of $f_r(n, e)$, where instead of considering the number of edges we consider the minimum degree. Define $k_r(n, \delta)$ to be the minimum number of $r$-cliques in graphs of order $n$ with minimum degree at least $\delta$. In addition, $k_{r\text{\tiny reg}}(n, \delta)$ is defined to be the minimum number of $r$-cliques in $\delta$-regular graphs of order $n$. It should be noted that there exist $n$ and $\delta$ such that $k_r(n, \delta) = 0$, but $k_{r\text{\tiny reg}}(n, \delta) > 0$. For example, if $r = 3$, $n$ odd and $2n/5 < \delta n < 2$, then it is easy to show that $k_3(n, \delta) = 0$.

† This research was supported by EPSRC.
However, a theorem of Andrásfai, Erdős and Sós [1] states that every triangle-free graph of order \( n \) with minimal degree greater than \( 2n/5 \) is bipartite. Since no regular graph with an odd number of vertices can be bipartite, \( k_3\text{reg}^r (n, \delta) \geq 0 \) for \( n \) odd and \( 2n/5 < \delta < n/2 \), whilst \( k_3(n, \delta) = 0 \). The author [5] evaluated \( k_3\text{reg}^r (n, \delta) \) for \( n \geq 10^7 \) odd and \( 2n/5 + \sqrt{n}/5 \leq \delta \leq n/2 \).

Throughout this paper, \( n \) and \( \delta \) always represent the number of vertices and the minimum degree respectively, whereas \( \beta \) represents the rescaled parameter \((1 - \delta/n)\). In other words, \( \delta = (1 - \beta)n \) with \( 0 < \beta \leq 1 \). Thus, \( \beta \) and \( \beta n \) are assumed to be a rational and an integer respectively. Furthermore, define the integer \( p \) to be \([\beta^{-1}] - 1\). Note that \( p \) is defined so that, by Turán’s theorem [11], \( k_r(n, (1 - \beta)n) > 0 \) for all \( n \) (such that \( \beta n \) is an integer) if and only if \( r < p + 1 \). Since the case \( \beta = 1 \) implies the trivial case \( \delta = 0 \), we may assume that \( 0 < \beta < 1 \). Furthermore, we consider the cases \( 1/(p + 1) \leq \beta < 1/p \) separately for positive integers \( p \). Hence, the condition \( p = 2 \) is equivalent to \( 1/3 \leq \beta < 1/2 \), that is, \( n/2 < \delta \leq 2n/3 \).

Next, we define a family \( \mathcal{G}(n, \beta) \) of graphs of order \( n \) with minimum degree \((1 - \beta)n\). The number of \( r \)-cliques in each of these graphs is small. Thus, we obtain an upper bound on \( k_r(n, \delta) \) (recalling that \( \delta = (1 - \beta)n \)).

**Definition 1.1.** Let \( n \) and \((1 - \beta)n\) be positive integers not both odd with \( 0 < \beta < 1 \). Define \( \mathcal{G}(n, \beta) \) to be the family of graphs \( G = (V, E) \) of order \( n \) satisfying the following properties. There is a partition of \( V \) into \( V_0, V_1, \ldots, V_{p-1} \) with \( |V_0| = (1 - (p - 1)\beta)n \) and \( |V_i| = \beta n \) for \( 1 \leq i \leq p - 1 \), where again \( p = [\beta^{-1}] - 1 \). For \( 0 \leq i < j \leq p - 1 \), the bipartite graph \( G[V_i, V_j] \) induced by the vertex classes \( V_i \) and \( V_j \) is complete. For \( 1 \leq i \leq p - 1 \), the subgraph \( G[V_i] \) induced by \( V_i \) is empty and \( G[V_0] \) is a \((1 - p\beta)n\)-regular graph such that the number of triangles in \( G[V_0] \) is minimal over all \((1 - p\beta)n\)-regular graphs of order \( |V_0| = (1 - (p - 1)\beta)n \).

Note that \( \mathcal{G}(n, \beta) \) is only defined if \( n \) and \((1 - \beta)n\) are not both odd. Thus, whenever we mention \( \mathcal{G}(n, \beta) \), we automatically assume that \( n \) or \((1 - \beta)n\) is even. Furthermore, we say \((n, \beta)\) is *feasible* if \( G[V_0] \) is triangle-free for \( G \in \mathcal{G}(n, \beta) \). Note that \( G[V_0] \) is regular of degree \((1 - p\beta)n \leq (1 - (p - 1)\beta)n/2 = |V_0|/2 \). Thus, if \( |V_0| \) is even, then \( G[V_0] \) is triangle-free. Therefore, for a given \( \beta \), there exist infinitely many choices of \( n \) such that \((n, \beta)\) is a feasible pair. If \((n, \beta)\) is not a feasible pair, then \( |V_0| \) is odd. Moreover, it is easy to show that \( k_3(G[V_0]) = k^r_3(n_0, \delta_0) = o(n^3) \), where \( n_0 = |V_0| = (1 - (p - 1)\beta)n \), \( \delta_0 = (1 - p\beta)n \) and \( k_r(H) \) is the number of \( r \)-cliques in a graph \( H \).

By Definition 1.1, every \( G \in \mathcal{G}(n, \beta) \) is \((1 - \beta)n\)-regular. In particular, for positive integers \( r \geq 3 \), the number of \( r \)-cliques in \( G \) is exactly

\[
k_r(G) = g_r(\beta)n^r + \binom{p-1}{r-3}(1 - p\beta)^{r-3}n^{r-3}k_3(G[V_0]),
\]

\[
= g_r(\beta)n^r + \binom{p-1}{r-3}(1 - p\beta)^{r-3}n^{r-3}k^r_3(n_0, \delta_0), \tag{1.1}
\]
where \( n_0 = (1 - (p - 1)\beta)n, \delta_0 = (1 - p\beta)n \) and

\[
g_r(\beta) = \binom{p - 1}{r} \beta^r + \binom{p - 1}{r - 1} (1 - (p - 1)\beta) \beta^{r-1} + \frac{1}{2} \left( \frac{p - 1}{r - 2} (1 - p\beta) (1 - (p - 1)\beta) \beta^{r-2} \right),
\]

with \( \binom{x}{y} \) defined to be 0 if \( x < y \) or \( y < 0 \). Since \( k_{3^{\text{reg}}}(n_0, \delta_0) = o(n^3) \), (1.1) becomes \( k_r(G) = (g_r(\beta) + o(1))n' \). In fact, most of the time, we consider the case when \((n, \beta)\) is feasible and the extremal graphs are members of \( G(n, \beta) \).

Recall that \( \delta = (1 - \beta)n \). Write \( g_r^*(n, \delta) = g_r(\beta)n' \). Since \( \beta \) is a function of \( n \) and \( \delta \), we abuse notation by writing ‘\((n, \delta)\) is feasible’ to mean \((n, \beta)\), and \( G(n, \delta) \) for \( G(n, \beta) \). We conjecture that if \((n, \delta)\) is feasible then \( G(n, \delta) \) is the extremal family for \( k_r(n, \delta) \) for \( 3 \leq r \leq p + 1 = [\beta^{-1}] = [(1 - \delta/n)^{-1}] \).

**Conjecture 1.2.** Let \( n \) and \( \delta \) be positive integers. Then

\[
k_r(n, \delta) \geq g_r^*(n, \delta)
\]

for positive integers \( r \). Moreover, for \( 3 \leq r \leq p + 1 = [(1 - \delta/n)^{-1}] \), equality holds if and only if \((n, \delta)\) is feasible and the extremal graphs are members of \( G(n, \delta) \).

By Turán’s theorem [11], the conjecture above is true when \( p = 1 \) or \( r > p + 1 \). If \( \delta = pn/(p + 1) \), then \( G(n, \delta) \) only consists of \( T_{p+1}(n) \), the \((p + 1)\)-partite Turán graph of order \( n \). Bollobás [2] proved that if \( (p + 1)n \) and \( e = (1 - 1/(p + 1))n^2/2 \), then \( f_r(n, e) = k_r(T_{p+1}(n)) \). Moreover, \( T_{p+1}(n) \) is the only graph of order \( n \) with \( e \) edges and \( f_r(n, e) \) \( r \)-cliques. Hence, it is an easy exercise to show that Conjecture 1.2 is true when \( \delta = pn/(p + 1) \).

It should be noted that since \( G(n, \delta) \) defines a family of regular graphs, we also conjecture that \( k_r^{\text{reg}}(n, \delta) \) is achieved by \( G \in G(n, \delta) \). However, we do not address the problem \( k_r^{\text{reg}}(n, \delta) \) here. Note that the extremal graphs of \( k_r(n, \delta) \) have minimum degree \( \delta \). For the remainder of the paper, all graphs are also assumed to be of order \( n \) with minimum degree \( \delta = (1 - \beta)n \) unless stated otherwise.

### 2. Main results

By our previous observation, Conjecture 1.2 is true for the following three cases: \( p = 1 \), \( r > p + 1 \) and \( \delta = pn/(p + 1) \). That leaves the situation when \( 3 \leq r \leq p + 1 \) and \( \delta > n/2 \). In Section 3, we prove Conjecture 1.2 for \( n/2 < \delta \leq 2n/3 \), as follows.

**Theorem 2.1.** Let \( n \) and \( \delta \) be positive integers with \( n/2 < \delta \leq 2n/3 \). Then

\[
k_3(n, \delta) \geq g_3^*(n, \delta).
\]

Moreover, equality holds if and only if \((n, \delta)\) is feasible and the extremal graphs are members of \( G(n, \delta) \).
The ideas in the proof, which is short, form the framework for our other results. The next case is that of $K_{p+2}$-free graphs. Notice that, by the definition of $p$, $G$ must contain $K_{p+1}$ but need not contain $K_{p+2}$. Conjecture 1.2 is proved for $K_{p+2}$-free graphs by the next theorem.

**Theorem 2.2.** Let $n$ and $\delta$ be positive integers. Let $G$ be a $K_{p+2}$-free graph of order $n$ with minimum degree $\delta$, where $p = \lceil(1 - \delta/n)^{-1}\rceil - 1$. Then,

$$k_r(G) \geq g^*_r(n, \delta)$$

for positive integers $r$. Moreover, for $3 \leq r \leq p + 1$ equality holds if and only if $(n, \delta)$ is feasible, and the extremal graphs are members of $G(n, \delta)$.

Theorem 2.2 is proved in Section 5, after some notation and basic inequalities have been set up in Section 4. Hence, the difficulty in proving Conjecture 1.2 is in handling $(p + 2)$-cliques. We discuss this situation in Section 6 for the case $p = 3$, and by a detailed analysis of 5-cliques in Section 7, proving Conjecture 1.2 for $2n/3 < \delta \leq 3n/4$, as follows.

**Theorem 2.3.** Let $n$ and $\delta$ be positive integers with $2n/3 < \delta \leq 3n/4$. Then

$$k_r(n, \delta) \geq g^*_r(n, \delta),$$

for positive integers $r$. Moreover, for $3 \leq r \leq 4$ equality holds if and only if $(n, \delta)$ is feasible and the extremal graphs are members of $G(n, \delta)$.

This theorem is the hardest in the paper. We have in fact proved Conjecture 1.2 for $3n/4 < \delta \leq 4n/5$ by a similar argument. It is too complicated to be included in this paper, but it can be found in [6]. For each positive integer $p \geq 5$, it is likely that by following the arguments in the proof of Theorem 2.3 one could construct a proof for Conjecture 1.2 when $(1 - 1/(p+1))n < \delta \leq (1 - 1/(p+1))n$.

We give two more results in support of Conjecture 1.2 in Section 8 and Section 9. The first is that for every positive integer $p$, Conjecture 1.2 holds for a positive proportion of values of $\delta$.

**Theorem 2.4.** For every positive integer $p$, there exists a (calculable) constant $\epsilon_p > 0$ so that if $n$ and $\delta$ are positive integers such that $(1 - 1/(p + 1) - \epsilon_p)n < \delta \leq (1 - 1/(p + 1))n$, then

$$k_r(n, \delta) \geq g^*_r(n, \delta),$$

for positive integers $r$. Moreover, for $3 \leq r \leq p + 1$ equality holds if and only if $(n, \delta)$ is feasible and the extremal graphs are members of $G(n, \delta)$.

Finally, using a different argument, we can show that Conjecture 1.2 holds in the case $r = p + 1$ (the largest value of $r$ for which $r$-cliques are guaranteed).
Theorem 2.5. Let $n$ and $\delta$ be positive integers. Then
\[ kp+1(n, \delta) \geq g^*_p(n, \delta), \]
where $p = [\left(1 - \delta/n\right)^{-1}] - 1$. Moreover, equality holds if and only if $(n, \delta)$ is feasible and the extremal graphs are members of $G(n, \delta)$.

3. Proof of Theorem 2.1

Here we prove Theorem 2.1, that is, Conjecture 1.2 for $n/2 < \delta \leq 2n/3$, so $1/3 < \beta < 1/2$ and $p = 2$. First, we would need the following simple proposition.

Proposition 3.1. Let $A$ be a finite set. Suppose $f, g : A \to \mathbb{R}$ with $f(a) \leq M$ and $g(a) \geq m$ for all $a \in A$. Then
\[ \sum_{a \in A} f(a)g(a) \leq m \sum_{a \in A} f(a) + M \sum_{a \in A} g(a) - mM|A|, \]
with equality if and only if, for each $a \in A$, $f(a) = M$ or $g(a) = m$.

Proof. Observe that \( \sum_{a \in A} (M - f(a))(g(a) - m) \geq 0. \)

Proof of Theorem 2.1. Let $G$ be a graph of order $n$ with minimum degree $\delta$. Since $G$ has at least $\delta n/2 = (1 - \beta)n^2/2$ edges,
\[ (1 - 2\beta)\beta nk_2(G) \geq (1 - 2\beta)(1 - \beta)n^3/2 = g_3(\beta)n^3. \]

Thus, in proving the inequality in Theorem 2.1, it is enough to show that $k_3(G) \geq (1 - 2\beta)\beta nk_2(G)$.

For an edge $e$, define $d(e)$ to be the number of triangles containing $e$ and write $D(e) = d(e)/n$. Clearly,
\[ n \sum_{e \in E(G)} D(e) = \sum_{e \in E(G)} d(e) = 3k_3(G). \]

In addition, $D(e) \geq 1 - 2\beta$ for each edge $e$, because each vertex in $G$ misses at most $\beta n$ vertices. Since $\beta < 1/2$, $D(e) > 0$ for all $e \in E(G)$ and so every edge is contained in a triangle. Let $T$ be a triangle in $G$. Similarly, define $d(T)$ to be the number of 4-cliques containing $T$, and write $D(T) = d(T)/n$. We claim that
\[ \sum_{e \in E(T)} D(e) \geq 2 - 3\beta + D(T). \tag{3.1} \]

Let $n_i$ be the number of vertices in $G$ with exactly $i$ neighbours in $T$ for $i = 0, 1, 2, 3$. Clearly, $n = n_0 + n_1 + n_2 + n_3$. By counting the number of edges incident with $T$, we obtain
\[ 3(1 - \beta)n \leq \sum_{v \in V(T)} d(v) = 3n_3 + 2n_2 + n_1 \leq 2n_3 + n_2 + n. \tag{3.2} \]
On the other hand, \( n_3 = d(T) \) and \( n_2 + 3n_3 = \sum_{e \in E(G)} d(e) \). Hence, (3.1) holds. Notice that if equality holds in (3.1) then \( d(v) = (1 - \beta)n \) for all \( v \in T \).

For an edge \( e \), define \( D_\beta(e) = \min\{D(e), \beta\} \). We claim that

\[
\sum_{e \in E(T)} D_\beta(e) \geq 2 - 3\beta \tag{3.3}
\]

for every triangle \( T \). If \( D(e) = D_\beta(e) \) for each edge \( e \) in \( T \), then (3.3) holds by (3.1). Otherwise, there exists \( e_0 \in E(T) \) such that \( D(e_0) \neq D_\beta(e_0) \). This means that \( D_\beta(e_0) = \beta \).

Recall that if equality holds in (3.1) then \( \beta \leq 1/2 \). Since equality holds in (3.3), \( \sum_{e \in E(T)} D(e) = 2 - 3\beta \) for triangles \( T \). Hence, \( D(T) = 0 \) for every triangle \( T \) by (3.1), so \( G \) is \( K_4 \)-free. In addition, by the remark following (3.1), \( G \) is \((1 - \beta)n\)-regular, because every vertex lies in a triangle as \( D(e) > 0 \) for all edges \( e \). Since equality holds in Proposition 3.1, either \( D(e) = 1 - 2\beta \) or \( D(e) = \beta \) for each edge \( e \). Recall that equality holds for (3.1), so every triangle \( T \) contains exactly one edge \( e_1 \) with \( D(e_1) = \beta \) and two edges, \( e_2 \) and \( e_3 \), with \( D(e_2) = D(e_3) = 1 - \beta \). Pick an edge \( e \) with \( D(e) = \beta \) and let \( W \) be the set of common neighbours of the end vertices of \( e \), so \( |W| = \beta n \). Clearly \( W \) is an independent set, otherwise \( G \) contains a \( K_4 \). For each \( w \in W \), \( d(w) = (1 - \beta)n \) implies \( N(w) = V(G) \setminus W \). Therefore, \( G[V(G) \setminus W] \) is \((1 - 2\beta)n\)-regular. If there is a triangle \( T \) in \( G[V(G) \setminus W] \), then \( T \cup w \) forms a \( K_4 \) for \( w \in W \). This contradicts the assumption that \( G \) is \( K_4 \)-free, so \( G[V(G) \setminus W] \) is triangle-free. Hence, \( G \) is a member of \( \mathcal{G}(n, \beta) \) and \((n, \beta)\) is feasible. Therefore, the proof is complete.

\( \square \)
4. Degree of a clique

Denote the set of $t$-cliques in $G[U]$ by $K_t(U)$ and write $k_r(U)$ for $|K_r(U)|$. If $U = V(G)$, we simply write $K_r$ and $k_r$.

Define the degree $d(T)$ of a $t$-clique $T$ to be the number of $(t + 1)$-cliques containing $T$. In other words, $d(T) = |\{S \in K_{t+1} : T \subset S\}|$. If $t = 1$, then $d(T)$ coincides with the ordinary definition of the degree for a vertex $v$. If $t = 2$, then $d(T)$ is the minimum degree $(1 + t)$-cliques containing $T$. Moreover, $d(T)$ is the number of common neighbours of the end vertices of the edge $uv$, that is, the codegree of $u$ and $v$. Clearly, $\sum_{T \in K_s} d(T) = (t + 1)k_{t+1}$ for $t \geq 1$. For convenience, we write $D(T)$ to denote $d(T)/n$.

Recall that $p = \lceil \beta^{-1} \rceil - 1$ and $1/(p + 1) \leq \beta < 1/p$. Let $G_0 \in G(n, \beta)$, with $(n, \beta)$ feasible. Let $T$ be a $t$-clique in $G_0$. It is natural to see that there are three types of cliques according to $|T \cap V_0|$. However, if we consider $d(T)$, then there are only two types. To be precise,

$$D(T) = \begin{cases} 1 - t\beta & \text{if } |V(T) \cap V_0| = 0, 1, \\ (p - t + 1)\beta & \text{if } |V(T) \cap V_0| = 2, \end{cases}$$

for $T \in K_t(G_0)$ and $2 \leq t \leq p + 1$. Next, define the functions $D_-$ and $D_+$ as follows. For a graph $G$ with minimum degree $\delta = (1 - \beta)n$, define

$$D_-(T) = \min\{D(T), (p - t + 1)\beta\}, \quad \text{and}$$

$$D_+(T) = D(T) - D_-(T) = \max\{0, D(T) - (p - t + 1)\beta\}$$

for $T \in K_t$ and $1 \leq t \leq p + 1$. We say that a clique $T$ is heavy if $D_+(T) > 0$. The graph $G$ is said to be heavy-free if and only if $G$ does not contain any heavy cliques. Now, we study some basic properties of $D(T)$, $D_-(T)$ and $D_+(T)$.

**Lemma 4.1.** Let $0 < \beta < 1$ and $p = \lceil \beta^{-1} \rceil - 1$. Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Suppose $S \in K_s$ and $T \in K_t(S)$ for $1 \leq t < s$. Then we have the following.

(i) $D(S) \geq 1 - s\beta$.

(ii) $D(S) \geq D(T) - (s - t)\beta$.

(iii) For $s \leq p + 1$, $D_-(T) \leq D_+(S) \leq D_+(T) + (s - t)\beta$.

(iv) If $T$ is heavy and $s \leq p + 1$ then $S$ is heavy.

(v) If $T$ is not heavy and $s \leq p + 1$, then $D_+(S) \leq (s - t)\beta$. In particular, if $t = s - 1 \leq p$, then $D_+(S) \leq \beta$.

Moreover, $G$ is $K_{p+2}$-free if and only if $G$ is heavy-free.

**Proof.** For each $v \in S$, there are at most $\beta n$ vertices not joined to $v$. Hence, $D(S) \geq 1 - s\beta$, so (i) is true. Similarly, consider the vertices in $S \setminus T$, so (ii) is also true. If $s \leq p + 1$ and $D_+(T) > 0$, then we have

$$D_+(S) + (p - s + 1)\beta \geq D(S) \geq D(T) - (s - t)\beta = D_+(T) + (p - t + 1)\beta - (s - t)\beta,$$
so the left inequality of (iii) is true. Since \( D(S) \leq D(T) \), the right inequality of (iii) is also true by the definition of \( D_+(S) \) and \( D_+(T) \). Hence, (iv) and (v) are true by the left and right inequalities in (iii) respectively. Notice that \( D(U) = D_+(U) \) for \( U \in K_{p+1} \). Hence, by (iv), \( G \) is \( K_{p+2} \)-free if and only if \( G \) is heavy-free.

Now we prove the generalized version of (3.1), that is, the sum of degrees of \( t \)-subcliques in an \( s \)-clique.

**Lemma 4.2.** Let \( 0 < \beta < 1 \). Let \( s \) and \( t \) be integers with \( 2 \leq t < s \). Suppose \( G \) is a graph of order \( n \) with minimum degree \((1-\beta)n\). Then

\[
\sum_{T \in \mathcal{K}_t(S)} D(T) \geq (1-\beta)s \binom{s}{t-1} - (t-1)\binom{s-1}{t} + \binom{s-2}{t-2} D(S)
\]

for \( S \in \mathcal{K}_s \). Moreover, if equality holds, then \( d(v) = (1-\beta)n \) for all \( v \in S \).

**Proof.** Let \( n_i \) be the number of vertices with exactly \( i \) neighbours in \( S \). The three equations

\[
\sum_i n_i = n, \tag{4.1}
\]

\[
\sum_i in_i = \sum_{v \in V(S)} d(v) \geq s(1-\beta)n, \tag{4.2}
\]

\[
\sum_i \binom{i}{t} n_i = \sum_{T \in \mathcal{K}_t(S)} D(T)n \tag{4.3}
\]

follow by counting the number of vertices, edges and \((t+1)\)-cliques respectively. Next, by considering \( (t-1)\binom{s-1}{t} \) (4.1) \(-\binom{s-2}{t-1} \) (4.2) \(+\binom{s-2}{t-2}\) (4.3), we have

\[
\sum_{T \in \mathcal{K}_t(S)} D(T)n \geq (1-\beta)s \binom{s-2}{t-1} - (t-1)\binom{s-1}{t} + \binom{s-2}{t-2} D(S) + \sum_{0 \leq i \leq s} x_i n_i,
\]

where \( x_i = \binom{i}{t} + (t-1)\binom{s-1}{t-1} - i\binom{s-2}{t-1} \). Notice that \( x_i = x_{i+1} + \binom{s-2}{t-1} - \binom{i}{t-1} \geq x_{i+1} \) for \( 0 \leq i \leq s-2 \). For \( i = s-1 \), we have

\[
x_{s-1} = \binom{s-1}{t} + (t-1)\binom{s-1}{t} - (s-1)\binom{s-2}{t-1} = t\binom{s-1}{t} - (s-1)\binom{s-2}{t-1} = 0.
\]

For \( i = s \), \( n_s = D(S)n \) and

\[
x_s = \binom{s}{t} + (t-1)\binom{s-1}{t} - s\binom{s-2}{t-1} = t\binom{s-1}{t} + (s-1)\binom{s-2}{t-1} - s\binom{s-2}{t-1} = (s-t+1)\binom{s-1}{t-1} - s\binom{s-2}{t-1}.
\]
This completes the proof of the lemma. \hfill \square

Most of the time, we are only interested in the case when \( s = t + 1 \). Hence, we state the following corollary.

**Corollary 4.3.** Let \( 0 < \beta < 1 \). Suppose \( G \) is a graph of order \( n \) with minimum degree \((1 - \beta)n\). Then

\[
\sum_{T \in \mathcal{K}_s(S)} D(T) \geq 2 - (t + 1)\beta + (t - 1)D(S)
\]

for \( S \in \mathcal{K}_{t+1} \) and integer \( t \geq 2 \). Moreover, if equality holds, then \( d(v) = (1 - \beta)n \) for all \( v \in S \).

In the next lemma, we show that the functions \( D \) in Lemma 4.2 can be replaced with \( D_- \).

**Lemma 4.4.** Let \( 0 < \beta < 1 \) and \( p = \lfloor \beta^{-1} \rfloor - 1 \). Let \( s \) and \( t \) be integers with \( 2 \leq t < s \leq p + 1 \). Suppose \( G \) is a graph of order \( n \) with minimum degree \((1 - \beta)n\). Then, for \( S \in \mathcal{K}_s \),

\[
\sum_{T \in \mathcal{K}_s(S)} D_-(T) \geq (1 - \beta)s\left(\frac{s - 2}{t - 1}\right) - (t - 1)\left(\frac{s - 1}{t}\right) + \left(\frac{s - 2}{t - 2}\right)D_-(S).
\]

**Proof.** Since \( D_+(S) \geq D_+(T) \) for every \( T \in \mathcal{K}_s(S) \) by Lemma 4.1(iii), there is nothing to prove by Lemma 4.2 if there are at most \( \binom{s - 2}{t - 2} \) heavy \( t \)-cliques in \( S \). Now suppose there are more than \( \binom{s - 2}{t - 2} \) heavy \( t \)-cliques in \( S \). In particular, \( S \) contains a heavy \( t \)-clique, so \( S \) is itself heavy with \( D_-(S) = (p + 1 - s)\beta \) by Lemma 4.1(iv). Thus, the right-hand side of the inequality is \( \binom{s}{t}(1 - t\beta) + \binom{s - 2}{t - 2}(p + 1)\beta - 1 \). By Lemma 4.1(i) we have that \( D_-(T) \geq (1 - t\beta) \) for \( T \in \mathcal{K}_s(S) \). Furthermore, by Lemma 4.1(iv) \( D_-(T) = (p + t - 1)\beta \) if \( T \) is heavy, so summing \( D_-(T) \) over \( T \in \mathcal{K}_s(S) \) gives

\[
\sum_{T \in \mathcal{K}_s(S)} D_-(T) \geq k_+(S)(p - t + 1)\beta + \left(\binom{s}{t} - k_+(S)\right)(1 - t\beta)
\]

\[
= \binom{s}{t}(1 - t\beta) + k_+(S)((p + 1)\beta - 1).
\]

This completes the proof of the lemma. \hfill \square

Define the function \( \tilde{D} : \mathcal{K}_{t+1} \to \mathbb{R} \) such that

\[
\tilde{D}(S) = \sum_{T \in \mathcal{K}_s(S)} D_-(T) - (2 - (t + 1)\beta + (t - 1)D_-(S))
\]

for \( S \in \mathcal{K}_{t+1} \) and \( 2 \leq t \leq p \). Hence, for \( s = t + 1 \), Lemma 4.4 gives the following corollary.
Corollary 4.5. Let $0 < \beta < 1$ and $p = \lceil \beta^{-1} \rceil - 1$. Let $t$ be an integer with $2 \leq t \leq p$. Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Then $\hat{D}(S) \geq 0$ for $S \in K_{t+1}$.

Next, we bound $\sum_{S \in K_{t+1}} \hat{D}(S)$ from above by using Proposition 3.1.

Lemma 4.6. Let $0 < \beta < 1$ and $p = \lceil \beta^{-1} \rceil - 1$. Let $t$ be an integer with $2 \leq t \leq p$. Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Then

$$\sum_{S \in K_{t+1}} \hat{D}(S) \leq (t - 1 + (p - 2t + 2)(t + 1)\beta)k_{t+1} + (t - 1) \sum_{S \in K_{t+1}} D_+(S)$$

$$- (1 - t\beta)(p - t + 1)\beta nk_t - (t - 1)(t + 2) \frac{k_{t+2}}{n} - (1 - t\beta)n \sum_{T \in K_t} D_+(T).$$

Moreover, equality holds if and only if, for each $T \in K_t$, either $D_-(T) = 1 - t\beta$ or $D_-(T) = (p - t + 1)\beta$.

Proof. Notice that the sum $\hat{D}(S)$ over $S \in K_{t+1}$ is equal to

$$\sum_{S \in K_{t+1}} \sum_{T \in K_t(S)} D_-(T) - (2 - (t + 1)\beta)k_{t+1} - (t - 1) \sum_{S \in K_{t+1}} D_-(S).$$

Consider each term separately. Since $D(S) = D_-(S) + D_+(S)$,

$$\sum_{S \in K_{t+1}} D_-(S) = \sum_{S \in K_{t+1}} D(S) - \sum_{S \in K_{t+1}} D_+(S) = \frac{(t + 2)k_{t+2}}{n} - \sum_{S \in K_{t+1}} D_+(S).$$

By interchanging the order of summation, we have

$$\sum_{S \in K_{t+1}} \sum_{T \in K_t(S)} D_-(T) = n \sum_{T \in K_t} D_-(T)D(T),$$

and by Proposition 3.1, taking $A = K_t$, $f = D_-$, $g = D$, $M = (p - t + 1)\beta$ and $m = 1 - t\beta$,

$$n \sum_{T \in K_t} D_-(T)D(T)$$

$$\leq (1 - t\beta)n \sum_{T \in K_t} D_-(T) + (p - t + 1)\beta n \sum_{T \in K_t} D(T) - (1 - t\beta)(p - t + 1)\beta nk_t$$

$$= (1 + (p - 2t + 1)\beta)n \sum_{T \in K_t} D(T) - (1 - t\beta)n \sum_{T \in K_t} D_+(T) - (1 - t\beta)(p - t + 1)\beta nk_t,$$

$$= (1 + (p - 2t + 1)\beta)(t + 1)k_{t+1} - (1 - t\beta)n \sum_{T \in K_t} D_+(T) - (1 - t\beta)(p - t + 1)\beta nk_t.$$

Hence, substituting these identities back into (4.4), we obtain the desired inequality in the lemma.

By Proposition 3.1, equality holds if and only if, for each $T \in K_t$, either $D(T) = 1 - t\beta$ or $D_-(T) = (p - t + 1)\beta$.

To keep our calculations simple, we are going to establish a few relationships between $g_t(\beta)$ and $g_{t+1}(\beta)$ in the next lemma.
Lemma 4.7. Let $0 < \beta < 1$ and $p = [\beta^{-1}] - 1$. Let $t$ be an integer with $2 \leq t \leq p$. Then

$$(t + 1)g_{t+1}(\beta) = (1 - t\beta)g_t(\beta) + \frac{1}{2} \left( \frac{p - 1}{t - 2} \right)(p + 1)((p + 1)\beta - 1)(1 - (p - 1)\beta)(1 - p\beta)\beta^{t-2},$$

$$g_{t+1}(\beta) = \frac{(1 - t\beta)(p - t + 1)\beta g_t(\beta) + (t - 1)(t + 2)g_{t+2}(\beta)}{t - 1 + (t + 1)(p - 2t + 2)\beta}.$$  

Moreover,

$$\frac{g_p(\beta)}{g_{p+1}(\beta)} = \frac{1}{\beta} \left( 1 + \frac{\beta g_{p-1}(\beta')}{(1 - \beta)g_p(\beta')} \right),$$

where $\beta' = \beta/(1 - \beta)$.

Proof. We fix $\beta$ (and $p$) and write $g_t$ to denote $g_t(\beta)$. Pick $n$ such that $(n, \beta)$ is feasible and let $G \in G(n, \beta)$ with partition classes $V_0, V_1, \ldots, V_{p-1}$ as described in Definition 1.1. Thus, for $T \in \mathcal{K}_t$, $D(T) = 1 - t\beta$ or $D(T) = (p - t + 1)\beta$. Since $D(T) = (p - t + 1)\beta$ if and only if $|V(T) \cap V_0| = 2$, there are exactly

$$\frac{1}{2} \left( \frac{p - 1}{t - 2} \right)(1 - (p - 1)\beta)(1 - p\beta)\beta^{t-2}n^t$$

t-cliques $T$ with $D(T) = (p - t + 1)\beta$. Also, we have

$$(t + 1)g_{t+1}n^{t+1} = (t + 1)k_{t+1} = n \sum_{T \in \mathcal{K}_t} D(T).$$

Hence, (4.5) is true, by expanding the right-hand side of the equation above. For $2 \leq s < p$, let $f_s$ and $f_{s+1}$ be (4.5) with $t = s$ and $t = s + 1$ respectively. Then (4.6) follows by considering $(p - s + 1)f_s - (s - 1)\beta f_{s+1}$.

Now let $G' = G \setminus V_{p-1}$. Notice that $G'$ is $(1 - 2\beta)n$-regular with $(1 - \beta)n$ vertices. We observe that $G'$ is a member of $G(n', \beta')$, where $n' = (1 - \beta)n$ and $\beta' = \beta/(1 - \beta)$. Observe that $[\beta'^{-1}] - 1 = p - 1$, so $1/p \leq \beta' < 1/(p - 1)$. Recall that $k_t(G) = g_t(\beta)n^t$ for all $2 \leq t \leq p$, so $k_{p+1}(G)g_p(\beta) = k_p(G)g_{p+1}(\beta)n$. Similarly, $k_p(G')g_{p-1}(\beta') = k_{p-1}(G')g_p(\beta')n$. By considering $\mathcal{K}_p(G)$ and $\mathcal{K}_{p+1}(G)$, we obtain the following two equations:

$$k_{p+1}(G) = \beta nk_p(G'),$$

$$k_p(G) = \beta nk_{p-1}(G') + k_p(G') = \beta n \frac{g_{p-1}(\beta')k_p(G')}{n'g_p(\beta')} + k_p(G')$$

$$= \left( 1 + \frac{\beta g_{p-1}(\beta')}{(1 - \beta)g_p(\beta')} \right)k_p(G').$$

By substituting (4.8) and (4.9) into $k_p(G)n/k_{p+1}(G) = g_p(\beta)/g_{p+1}(\beta)$, we obtain (4.7). The proof is complete.

5. $K_{p+2}$-free graphs

In this section, all graphs are assumed to be $K_{p+2}$-free. Lemma 4.1 implies that these graphs are also heavy-free. This means that $D_+(T) = 0$ and $D(T) \leq (p - t + 1)\beta$ for all...
\( T \in \mathcal{K}_t \) and \( t \leq p + 1 \). We prove the theorem below, which easily implies Theorem 2.2 as \( g_2(\beta)n^2 = (1 - \beta)n^2/2 \leq k_2(G) \).

**Theorem 5.1.** Let 0 < \( \beta < 1 \) and \( p = [\beta^{-1}] - 1 \). Suppose \( G \) is a \( K_{p+2} \)-free graph of order \( n \) with minimum degree \((1 - \beta)n\). Then

\[
\frac{k_s(G)}{g_s(\beta)n^t} \geq \frac{k_i(G)}{g_i(\beta)n^t} \tag{5.1}
\]

holds for \( 2 \leq t < s \leq p + 1 \). Moreover, the following three statements are equivalent:

(i) equality holds for some \( 2 \leq t < s \leq p + 1 \),

(ii) equality holds for all \( 2 \leq t < s \leq p + 1 \),

(iii) the pair \((n, \beta)\) is feasible and \( G \) is a member of \( \mathcal{G}(n, \beta) \).

**Proof.** Fix \( \beta \) and write \( g_t \) to denote \( g_t(\beta) \). Recall that \( D_+(T) = 0 \) for cliques \( T \). By Corollary 4.5 and Lemma 4.6, we have

\[
k_{t+1} \geq \frac{(1 - t\beta)(p + t + 1)\beta n k_t + (t - 1)(t + 2)k_{t+2}}{t - 1 + (p - 2t + 2)(t + 1)\beta}. \tag{5.2}
\]

First, we are going to prove (5.1). It is sufficient to prove the case when \( s = t + 1 \). We proceed by induction on \( t \) from above. For \( t = p \), \( k_{p+2} = 0 \) and so (5.2) becomes

\[
(p - 1 - (p - 2)(p + 1)\beta)k_{p+1} \geq (1 - p\beta)\beta n k_p.
\]

Since \( g_{p+2} = 0 \), we have \( k_{p+1}/g_{p+1}n^{p+1} \geq k_p/g_p n^p \) by (4.6). Hence, (5.1) is true for \( t = p \). For \( t < p \), (5.2) becomes

\[
(t - 1 + (t + 1)(p - 2t + 2)\beta)k_{t+1} \geq (1 - t\beta)(p + 1 - t)\beta n k_t + (t - 1)(t + 2)k_{t+2}/n
\]

\[
\geq (1 - t\beta)(p + 1 - t)\beta n k_t + (t - 1)(t + 2)g_{t+2}k_{t+1}/g_{t+1}, \tag{5.3}
\]

by the induction hypothesis. Thus, (5.1) follows from (4.6).

It is clear that (iii) implies both (i) and (ii) by Definition 1.1 and the feasibility of \((n, \beta)\). Suppose (i) holds, so equality holds in (5.1) for \( t = t_0 \) and \( s = s_0 \) with \( t_0 < s_0 \). We claim that equality must also hold for \( t = p \) and \( s = p + 1 \). Suppose the claim is false and equality holds for \( t = t_0 \) and \( s = s_0 \), where \( s_0 \) is maximal. Since equality holds for \( t = t_0 \), by (5.1), equality holds for \( t = t_0, \ldots, s_0 - 1 \) with \( s = s_0 \). We may assume that \( t = s_0 - 1 \) and \( s_0 \neq p + 1 \) and \( k_{s_0 + 1}/g_{s_0 + 1}n > k_{s_0}/g_{s_0} \). However, this would imply a strict inequality in (5.3), contradicting the fact that equality holds for \( s = s_0 \) and \( t = s_0 - 1 \). Thus, the proof of the claim is complete, that is, if (i) holds then equality holds in (5.1) for \( t = p \) and \( s = p + 1 \).

Therefore, to prove that (i) implies (iii), it is sufficient to show that if \( k_{p+1}/g_{p+1}n^{p+1} = k_p/g_p n^p \), then \((n, \beta)\) is feasible and \( G \) is a member of \( \mathcal{G}(n, \beta) \). We proceed by induction on \( p \). It is true for \( p = 2 \) by Theorem 2.1, so we may assume \( p \geq 3 \). Since equality holds in (5.1), we have equality in (5.2), Corollary 4.5 and Lemma 4.6. Since \( D_+ \) is a zero function, equality in Corollary 4.5 implies equality in Corollary 4.3 and so \( G \) is \((1 - \beta)n\)-regular, as every vertex is a \((p + 1)\)-clique. In addition, for each \( T \in \mathcal{K}_p \), either \( D(T) = 1 - p\beta \) or
$D(T) = \beta$ by equality in Lemma 4.6. Moreover, Corollary 4.3 implies that $\sum_{T \in \mathcal{K}_p(S)} D(T) \geq 2 - (p + 1)\beta$ for $S \in \mathcal{K}_{p+1}$. Thus, there exists $T \in \mathcal{K}_p(S)$ with $D(T) = \beta$. Pick $T \in \mathcal{K}_p$ with $D(T) = \beta$ and let $W = \bigcap \{ N(v) : v \in V(S) \}$, so $|W| = \beta$. Since $G$ is $K_{p+2}$-free, $W$ is a set of independent vertices. For each $w \in W$, $d(w) = (1 - \beta)n$, so $N(w) = V(G) \setminus W$. Thus, the graph $G' = G[V(G) \setminus W]$ is $(1 - \beta)n'$-regular, where $n' = (1 - \beta)n$, $\beta'n' = (1 - 2\beta)n$ and $\beta' = \beta/(1 - \beta)$. Note that $[\beta' - 1] - 1 = p-1$. Since $G$ is $K_{p+2}$-free, $G'$ is $K_{p+1}$-free. Also, $k_{p+1}(G) = \beta nk_p(G')$ and

$$k_p(G) = \beta nk_{p-1}(G') + k_p(G') \overset{\text{by (5.1)}}{\leq} \beta \frac{g_{p-1}(\beta')k_p(G')}{g_p(\beta')} + k_p(G') = \left(1 + \beta \frac{g_{p-1}(\beta')}{(1 - \beta)g_p(\beta')}\right)k_p(G') \overset{\text{by (4.7)}}{=} \frac{g_p(\beta)}{g_{p+1}(\beta)} k_p(G').$$

Hence,

$$g_p(\beta)nk_p(G') = g_p(\beta)k_{p+1}(G) \overset{\text{by (5.1)}}{=} g_{p+1}(\beta)nk_p(G) \overset{\text{by (5.4)}}{\leq} g_p(\beta)nk_p(G').$$

Therefore, we have $k_p(G')/g_p(\beta)n^p = k_{p-1}(G')/g_{p-1}(\beta)n^{p-1}$. By the induction hypothesis, $G' \in \mathcal{G}(n', \beta')$, which implies $G \in \mathcal{G}(n, \beta)$. This completes the proof of the theorem. \hfill \square

6. Evaluating $k_r(n, \delta)$ for $2n/3 < \delta \leq 3n/4$

By Theorem 2.2, in order to prove Conjecture 1.2 it remains to handle the heavy cliques. However, even though both Corollary 4.5 and Lemma 4.6 are sharp by considering $G \in \mathcal{G}(n, \beta)$, they are not sufficient to prove Conjecture 1.2, even for the case when $2n/3 < \delta \leq 3n/4$ by the observation below. Let $2n/3 < \delta \leq 3n/4$, $1/4 \leq \beta < 1/3$ and $p = 3$. By Corollary 4.5 and Lemma 4.6, we have

$$(1 + 3\beta)k_3 + \sum_{T \in \mathcal{K}_3} D_+(T) \geq 2(1 - 2\beta)\beta nk_2 + \frac{4}{n}k_4 + (1 - 2\beta)n \sum_{e \in \mathcal{K}_2} D_+(e),$$

$$(2 - 4\beta)k_4 + 2 \sum_{S \in \mathcal{K}_4} D_+(S) \geq (1 - 3\beta)\beta nk_3 + \frac{10}{n}k_5 + (1 - 3\beta)n \sum_{T \in \mathcal{K}_3} D_+(T),$$

for $t = 2$ and $t = 3$ respectively. Since $D_-$ is a zero function on 4-cliques,

$$\sum_{S \in \mathcal{K}_4} D_+(S) = \sum_{S \in \mathcal{K}_4} D(S) = 5k_5/n.$$
Lemma 6.1. Let $1/4 \leq \beta < 1/3$. Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Then, for $T \in \mathcal{K}_3$, 
\[
\tilde{D}(T) \geq \left(1 - \frac{2}{29 - 75\beta}\right)\frac{4\beta - 1}{1 - 2\beta} D_+^{\prime}(T) - (1 - 2\beta) \sum_{e \in \mathcal{K}_2(T)} \frac{D_+(e)}{D_+(e) + \beta}. \tag{6.3}
\]
Moreover, if equality holds then $T$ is not heavy and $d(v) = (1 - \beta)n$ for all $v \in T$.

Proof. Let $c$ be $(1 - 2/(29 - 75\beta))(4\beta - 1)/(1 - 2\beta)$. Corollary 4.5 gives $\tilde{D}(T) \geq 0$, so we may assume that $T$ is heavy. In addition, Corollary 4.3 implies that
\[
\tilde{D}(T) + \sum_{e \in \mathcal{K}_2(T)} D_+(e) \geq D_+(T). \tag{6.4}
\]
Since $c < 1$, we may further assume that $T$ contains at least one heavy edge, or else (6.4) holds as (6.4) becomes $\tilde{D}(T) \geq D_+(T) > cD_+(T)$. Let $e_0 \in \mathcal{K}_2(T)$ with $D_+(e_0)$ maximal. By substituting (6.4) into (6.3), it is sufficient to show that the function
\[
f = \left(1 - \frac{1 - 2\beta}{D_+(e_0) + 2\beta}\right)\tilde{D}(T) - \left(c - \frac{1 - 2\beta}{D_+(e_0) + 2\beta}\right)D_+(T)
\]
is non-negative.

First consider the case when $D_+(T) \leq 1 - 3\beta$. Lemma 4.1(iii) implies $D_+(e_0) \leq D_+(T) \leq 1 - 3\beta$. Hence,
\[
\frac{1 - 2\beta}{D_+(e_0) + 2\beta} - c \geq \frac{1 - 2\beta}{1 - \beta} - c > 0.
\]
Also, $1 - 2\beta \leq 2\beta < D_+(e_0) + 2\beta$. Therefore, $f > 0$ by considering the coefficients of $\tilde{D}(T)$ and $D(T)$. Hence, we may assume $D_+(T) > 1 - 3\beta$. Since $T$ is heavy, $D_-(T) = \beta$. Therefore, by the definition of $\tilde{D}$, we have
\[
\tilde{D}(T) = \sum_{e \in \mathcal{K}_2(T)} D_-(e) - 2(1 - \beta). \tag{6.5}
\]
We split into different cases separately depending on the number of heavy edges in $T$.

Suppose all edges are heavy. Thus, $\tilde{D}(T) = 2(4\beta - 1)$ by (6.5), because $D_-(e) = 2\beta$ for all edges $e$ in $T$. Clearly $D_+(T) = D(T) - \beta \leq 1 - \beta$. Hence, (6.3) is true as
\[
\tilde{D}(T) = 2(4\beta - 1) \geq (4\beta - 1)(1 - \beta)/(1 - 2\beta) \geq cD_+(T).
\]
Thus, there exists an edge in $T$ that is not heavy and $D_+(T) \leq \beta$ by Lemma 4.1(v).

Suppose $T$ contains one or two heavy edges. We are going to show that in both cases
\[
\tilde{D}(T) \geq 2(D_+(T) - (1 - 3\beta)).
\]
First assume that there is exactly one heavy edge in $T$. Let $e_1$ and $e_2$ be the two non-heavy edges in $T$. Note that $D_-(e_i) = D(e_i) \geq D(T) = D_+(T) + \beta$ for $i = 1, 2$. Thus, (6.5) and Lemma 4.1 imply that $\tilde{D}(T) \geq 2(D_+(T) - (1 - 3\beta))$. Assume that $T$ contains two heavy edges. Let $e_1$ be the non-heavy edge in $T$. Similarly, we have $D_-(e_1) \geq D_+(T) + \beta$.
that \( D_+(T) \leq \beta \), so (6.5) and Lemma 4.1 imply

\[
\tilde{D}(T) \geq (4\beta + D_+(T) - (1 - 3\beta)) \\
= 4\beta - 1 + D_+(T) - (1 - 3\beta) \geq 2(D_+(T) - (1 - 3\beta)).
\]

Since \( \tilde{D}(T) \geq 2(D_+(T) - (1 - 3\beta)) \), in proving (6.3), it is enough to show that

\[
D(e_0)f = (D_+(e_0) + 2\beta)f \\
\geq 2(D_+(e_0) + 4\beta - 1)(D_+(T) - (1 - 3\beta)) \\
- ((D_+(e_0) + 2\beta)c - (1 - 2\beta))D_+(T)
\]

is non-negative for \( 0 < D_+(e_0) \leq D_+(T) \) and \( 1 - 3\beta \leq D_+(T) \leq \beta \). Notice that for a fixed \( D_+(T) \) it is enough to check the boundary points of \( D_+(e_0) \). For \( D_+(e_0) = 0 \), we have

\[
D(e_0)f \geq (2(3-c)\beta - 1)(1 - 3\beta) \geq 2(1 - 2\beta)(1 - 3\beta) > 0.
\]

For \( D_+(e_0) = D_+(T) \), the right-hand side of (6.6) becomes a quadratic function in \( D_+(T) \). Moreover, both coefficients of \( D_+(T)^2 \) and \( D_+(T) \) are positive. Thus, it is enough to check for \( D_+(T) = 1 - 3\beta \). For \( D_+(T) = D_+(e_0) = 1 - 3\beta \), (6.6) becomes

\[
D(e_0)f \geq (1 - c - (2 - c)\beta)(1 - 3\beta) > 0.
\]

Hence, we have proved the inequality in Lemma 6.1.

It is easy to check that if equality holds in (6.3) then \( D_+(T) = 0 \). Thus, for all edges \( e \) in \( T \), \( D_+(e) = 0 \) by Lemma 4.1. Furthermore, equality holds in (6.4), so equality holds in Corollary 4.3 as \( D_+(T) = 0 = D_+(e) \). Hence, \( d(v) = (1 - \beta)n \) for \( v \in S \). This completes the proof of the lemma.

Together with Lemma 4.6 with \( t = 2 \), we obtain the strengthening of (6.1).

**Corollary 6.2.** Let \( 1/4 \leq \beta < 1/3 \). Suppose \( G \) is a graph of order \( n \) with minimum degree \( (1 - \beta)n \). Then

\[
(1 + 3\beta)k_3 + \frac{2}{1 - 2\beta} \left( 1 - 3\beta + \frac{4\beta - 1}{29 - 75\beta} \right) \sum_{T \in \mathcal{K}_3} D_+(T) \geq 2(1 - 2\beta)\beta nk_2 + 4\frac{k_4}{n}
\]

holds. Moreover, if equality holds, then \( G \) is \( (1 - \beta)n \)-regular and for each edge \( e \), either we have \( D(e) = 1 - 2\beta \) or \( D(e) = 2\beta \).

Note that by mimicking the proof of Lemma 6.1, we could obtain a strengthening of Corollary 4.5 for \( t = 3 \). It would lead to a strengthening of (6.2). However, it is still not sufficient to prove Conjecture 1.2 when \( \beta \) is close to \( 1/3 \). Instead, we prove the following statement. The proof requires a detailed analysis of \( \mathcal{K}_5 \), so it is postponed to Section 7.
Lemma 6.3. Let $1/4 \leq \beta < 1/3$. Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Then
\[
(2 - 4\beta)k_4 \geq (1 - 3\beta)\beta nk_3 + \left(1 - 3\beta + \frac{4\beta - 1}{29 - 75\beta}\right)n \sum_{T \in K_3} D_+(T).
\] (6.7)
Moreover, equality holds only if $(n, \beta)$ is feasible, and $G \in \mathcal{G}(n, \beta)$.

By using the two strengthened versions of (6.1) and (6.2), that is, Corollary 6.2 and Lemma 6.3, we prove the theorem below, which implies Theorem 2.3.

Theorem 6.4. Let $1/4 \leq \beta < 1/3$. Let $s$ and $t$ be integers with $2 \leq t \leq s \leq 4$. Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Then
\[
\frac{k_s(G)}{g_s(\beta)n^t} \geq \frac{k_t(G)}{g_t(\beta)n^t}.
\]
Moreover, the following three statements are equivalent:

(i) equality holds for some $2 \leq t < s \leq 4$,
(ii) equality holds for all $2 \leq t < s \leq 4$,
(iii) the pair $(n, \beta)$ is feasible, and $G$ is a member of $\mathcal{G}(n, \beta)$.

Proof. Recall that $p = 3$ as $1/4 \leq \beta < 1/3$, so
\[
g_2(\beta) = (1 - \beta)/2, \quad g_3(\beta) = (1 - 2\beta)^2\beta \quad \text{and} \quad g_4 = (1 - 2\beta)(1 - 3\beta)^2/2.
\]
Note that in proving the inequality, it is sufficient to prove the case when $s = t + 1$. Lemma 6.3 states that $(2 - 4\beta)k_4 \geq (1 - 3\beta)\beta nk_3$. This implies $k_4/g_4(\beta)n^4 \geq k_3/g_3(\beta)n^3$ by (4.6) with $t = 3$. Hence, the theorem is true for $t = 3$. For $t = 2$, by substituting Corollary 6.2 into Lemma 6.3, we obtain
\[
(1 + 3\beta)k_3 + \frac{2}{1 - 2\beta} \left(1 - 3\beta + \frac{4\beta - 1}{29 - 75\beta}\right) \sum_{T \in K_3} D_+(T) \geq 2(1 - 2\beta)\beta nk_2
\]
\[
+ \frac{4}{(2 - 4\beta)n} \left((1 - 3\beta)\beta nk_3 + \left(1 - 3\beta + \frac{4\beta - 1}{29 - 75\beta}\right)n \sum_{T \in K_3} D_+(T)\right).
\]
Observe that the $\sum D_+(T)$ terms on both sides cancel. Hence, after rearrangement, we have $(1 - \beta)k_3 \geq 2(1 - 2\beta)^2\beta nk_2$. Thus, $k_3/g_3(\beta)n^3 \geq k_2/g_2(\beta)n^3$ as required.

This is clear that (iii) implies (i) and (ii) by the construction of $\mathcal{G}(n, \beta)$ and the feasibility of $(n, \beta)$. Suppose (i) holds, so equality holds for some $2 \leq t < s \leq 4$. It is easy to deduce that equality also holds for $s = 4$ and $t = 3$. By Lemma 6.3, $(n, \beta)$ is feasible, and $G \in \mathcal{G}(n, \beta)$.

7. Proof of Lemma 6.3

In this section, $T$, $S$ and $U$ always denote a 3-clique, a 4-clique and a 5-clique respectively. Before presenting the proof, we recall some basic facts about $T$, $S$ and $U$. Observe that $D_-(S) = 0$ for $S \in K_4$, so $D_+(S) = D(S)$. Recall that $D(S) = \sum_{T \in K_3(S)} D_-(T) - (2 - 4\beta)$. 
Lemma 7.1. Let $T_1, \ldots, T_4$ be triangles in $S$ with $D(T_i) \leq D(T_{i+1})$ for $1 \leq i \leq 3$. Since $D_+(T) \leq \beta$, we have

$$
\bar{D}(S) = \begin{cases} 
2(4\beta - 1) & \text{if } k_3^+(S) = 4, \\
4\beta - 1 + (D(T_1) - (1 - 3\beta)) & \text{if } k_3^+(S) = 3, \\
D(T_1) + D(T_2) - 2(1 - 3\beta) & \text{if } k_3^+(S) = 2,
\end{cases}
$$

(7.1)

where $k_3^+(S)$ is the number of heavy triangles in $S$. Also recall that $D(T) \geq 1 - 3\beta$ by Lemma 4.1(i). We will often make reference to these formulae throughout this section.

Define the function $\eta : \mathcal{K}_4 \to \mathbb{R}$ to be

$$
\eta(S) = \bar{D}(S) - \frac{4\beta - 1}{29 - 75\beta} \sum_{T \in \mathcal{K}_3(S)} \frac{D_+(T)}{D_+(T) + \beta}
$$

for $S \in \mathcal{K}_4$. Recall that for a heavy triangle $T$, $D(T) = D_+(T) + \beta$. Thus, only heavy 3-cliques in $S$ contribute to $\sum D_+(T)/(D_+(T) + \beta)$. A 4-clique $S$ is called bad if $\eta(S) < 0$, otherwise it is called good. The sets of bad and good 4-cliques are denoted by $\mathcal{K}_4^{\text{bad}}$ and $\mathcal{K}_4^{\text{good}}$ respectively. In the lemma below, we identify the structure of a bad 4-clique.

**Lemma 7.1.** Let $1/4 \leq \beta < 1/3$. Let

$$
\Delta = (1 - 3\beta)(1 + \epsilon) \quad \text{and} \quad \epsilon = (4\beta - 1)(150\beta^2 - 137\beta + 30).
$$

Suppose $G$ is a graph of order $n$ with minimum degree $(1 - \beta)n$. Let $S$ be a bad 4-clique. Then, the following hold:

(i) $S$ contains exactly one heavy edge and two heavy triangles,
(ii) $0 < D(S) < \Delta$,
(iii) $D(T) + D(T') < 2\Delta$, where $T$ and $T'$ are the two non-heavy triangles in $S$.

**Proof.** Let $T_1, \ldots, T_4$ be triangles in $S$ with $D(T_i) \leq D(T_{i+1})$ for $1 \leq i \leq 3$. We may assume that $D_+(T_4) > 0$, otherwise $S$ is good by Corollary 4.5 as $\eta(S) = \bar{D}(S) \geq 0$. Hence, $S$ is also heavy by Lemma 4.1(iv). We separate cases by the number of heavy triangles in $S$.

First, suppose all triangles are heavy. Hence, $\bar{D}(S) = 2(4\beta - 1)$ by (7.1). Clearly, $D_+(T_i) \leq 1 - \beta$ for $1 \leq i \leq 4$, so

$$
\eta(S) \geq 2(4\beta - 1) - \frac{4\beta - 1}{29 - 75\beta} \sum_{T \in \mathcal{K}_3(S)} \frac{D_+(T)}{D_+(T) + \beta}
$$

$$
\geq 2(4\beta - 1) \left(1 - \frac{2(1 - \beta)}{29 - 75\beta}\right) = \frac{2(4\beta - 1)(27 - 73\beta)}{29 - 75\beta} \geq 0.
$$

This contradicts the assumption that $S$ is bad. Thus, not all triangles in $S$ are heavy, so $0 < D(S) \leq \beta$ by Lemma 4.1(v). Also, $D_+(T) \leq D_+(S) = D(S) \leq \beta$. 

\begin{center}
*Cliques in Graphs With Bounded Minimum Degree*
\end{center}
Suppose all but one triangles are heavy, so \( \tilde{D}(S) \geq 4\beta - 1 \) by (7.1). Hence, 
\[
\eta(S) \geq 4\beta - 1 - \frac{4\beta - 1}{29 - 75\beta} \sum_{T \in K(3)} \frac{D_+(T)}{D_+(T) + \beta} \\
\geq (4\beta - 1) \left(1 - \frac{3}{2(29 - 75\beta)} \right) (D(S) + \beta) \\
\geq (4\beta - 1) \left(1 - \frac{3}{2(29 - 75\beta)} \right) \frac{5(4\beta - 1)(11 - 30\beta)}{2(29 - 75\beta)} \geq 0,
\]
which is a contradiction.

Suppose there is only one heavy triangle, \( T_4 \), in \( S \). Corollary 4.3 implies \( \tilde{D}(S) + D_+(T_4) \geq 2D_+(S) = 2D(S) \). Note that \( D_+(T_4) \leq D_+(S) = D(S) \), so \( \tilde{D}(S) \geq D(S) \). Thus, 
\[
\eta(S) \geq D(S) - \frac{4\beta - 1}{29 - 75\beta} \frac{D_+(T_4)}{D_+(T_4) + \beta} \geq D(S) - \frac{4\beta - 1}{29 - 75\beta} D(S) + \beta \\
= \left(1 - \frac{4\beta - 1}{29 - 75\beta} D(S) + \beta\right) D(S) \geq \left(1 - \frac{4\beta - 1}{(29 - 75\beta)}\right) D(S) > 0.
\]
Hence, \( S \) has exactly two heavy triangles, namely \( T_3 \) and \( T_4 \). If \( D(S) \geq \Delta \), then 
\[
\eta(S) = D(T_1) + D(T_2) - 2(1 - 3\beta) - \frac{4\beta - 1}{29 - 75\beta} \left( \frac{D_+(T_3)}{D_+(T_3) + \beta} + \frac{D_+(T_4)}{D_+(T_4) + \beta} \right) \\
\geq 2(D(S) - (1 - 3\beta)) - \frac{2(4\beta - 1)}{29 - 75\beta} D(S) + \beta \\
> 2(1 - 3\beta)\epsilon - \frac{2(4\beta - 1)}{29 - 75\beta} \frac{\Delta}{\Delta + \beta} \\
\geq 2(1 - 3\beta)\epsilon - \frac{2(4\beta - 1)\Delta}{(29 - 75\beta)(1 - 2\beta)} = 0.
\]
Thus, \( D(S) < \Delta \). If \( D(T_1) + D(T_2) \geq 2\Delta \), then \( \tilde{D}(S) \geq 2(\Delta - (1 - 3\beta)) = 2(1 - 3\beta)\epsilon \) by (7.1). Moreover, since \( D_+(T_i) \leq D(S) < \Delta \) for \( i = 3, 4 \), 
\[
\eta(S) > 2(1 - 3\beta)\epsilon - \frac{2(4\beta - 1)}{29 - 75\beta} \frac{\Delta}{\Delta + \beta} \geq 2(1 - 3\beta)\epsilon - \frac{2(4\beta - 1)\Delta}{(29 - 75\beta)(1 - 2\beta)} = 0.
\]
Thus, (iii) is true.

We have shown that \( S \) contains exactly two heavy triangles. Therefore, to prove (i), it is sufficient to prove that \( S \) contains exactly one heavy edge. A triangle containing a heavy edge is heavy by Lemma 4.1(iv). Since \( S \) contains two heavy triangle, there is at most one heavy edge in \( S \). It is enough to show that if \( S \) does not contain any heavy edge and \( D(S) < \Delta \), then \( S \) is good, which is a contradiction. Assume that \( S \) contains no heavy edge. Let \( e_i = T_i \cap T_4 \) be an edge of \( T_4 \) for \( i = 1, 2, 3 \). We claim that \( \tilde{D}(S) \geq D_+(T_4) \). By Corollary 4.3, taking \( S = T_4 \) and \( r = 2 \), we obtain 
\[
D(e_1) + D(e_2) + D(e_3) \geq 2 - 3\beta + D(T_4), \\
D(e_1) + D(e_2) \geq 2 - 4\beta + D_+(T_4),
\]
as \( D(e_3) \leq 2\beta \) and \( D_-(T_4) = \beta \). By Lemma 4.1(ii), we get 
\[
D(T_1) + D(T_2) \geq D(e_1) + D(e_2) - 2\beta \geq 2(1 - 3\beta) + D_+(T_4).
\]
Hence, \( \tilde{D}(S) \geq D_+(T_4) \) by (7.1). Therefore,

\[
\eta(S) \geq D_+(T_4) - \frac{4\beta - 1}{29 - 75\beta} \sum_{T \in \mathcal{K}_4(S)} \frac{D_+(T)}{D_+(T) + \beta} \\
\geq \left( 1 - \frac{2(4\beta - 1)}{(29 - 75\beta)(D_+(T_4) + \beta)} \right) D_+(T_4) \\
\geq \left( 1 - \frac{2(4\beta - 1)}{(29 - 75\beta)\beta} \right) D_+(T_4) > 0,
\]

and so \( S \) is good, a contradiction. This completes the proof of the lemma.

Next, we study the relationship between the number of heavy edges and bad 4-cliques in a 5-clique \( U \).

**Lemma 7.2.** Let \( 1/4 \leq \beta < 1/3 \). Suppose \( G \) is a graph of order \( n \) with minimum degree \( (1 - \beta)n \). Let \( U \in \mathcal{K}_5 \) with \( h \geq 2 \) heavy edges and \( b \) bad 4-cliques. Then \( b \leq 2h/(h - 1) = 2 + 2/(h - 1) \). Moreover, if there exist two heavy edges sharing a common vertex, \( b \leq 3 \).

**Proof.** Define \( H \) to be the graph induced by the heavy edges in \( U \). Write \( u_S \) for the vertex in \( U \) not in \( S \in \mathcal{K}_4(U) \). This defines a bijection between \( V(U) \) and \( \mathcal{K}_4(U) \). If \( S \) is bad, \( u_S \) is adjacent to all but one heavy edge by Lemma 7.1(i). By summing the degrees of \( H \),

\[
2h = \sum_{S \in \mathcal{K}_4(U)} d(u_S) \geq b(h - 1).
\]

Thus, \( b \leq 2h/(h - 1) \).

If there exist two heavy edges sharing a common vertex in \( H \), then every bad 4-clique must miss one of the vertices of these two heavy edges. Hence, \( b \leq 3 \).

We are now ready to prove Lemma 6.3.

**Proof of Lemma 6.3.** We now claim that in order to show that the inequality in Lemma 6.3 holds, it is enough to prove that \( \sum_{S \in \mathcal{K}_4} \eta(S) \geq 0 \). If \( \sum_{S \in \mathcal{K}_4} \eta(S) \geq 0 \), then Lemma 4.6 with \( t = 3 \) implies that

\[
0 \leq \sum_{S \in \mathcal{K}_4} \eta(S) = \sum_{S \in \mathcal{K}_4} \tilde{D}(S) - \frac{4\beta - 1}{29 - 75\beta} n \sum_{T \in \mathcal{K}_3} D_+(T) \\
\leq (2 - 4\beta)k_4 - (1 - 3\beta)\beta nk_3 - \left( 1 - 3\beta + \frac{4\beta - 1}{29 - 75\beta} \right) n \sum_{T \in \mathcal{K}_3} D_+(T) \\
+ 2 \sum_{S \in \mathcal{K}_4} D_+(S) - 10k_5/n,
\]

where the last inequality is due to Lemma 4.6 with \( t = 3 \). Observe that \( \sum_{S \in \mathcal{K}_4} D_+(S) = \sum_{S \in \mathcal{K}_4} D(S) = 5k_5/n \), so the terms with \( \sum D_+(S) \) and \( k_5/n \) cancel. Rearranging the inequality, we obtain the inequality in Lemma 6.3.

Suppose \( \sum_{S \in \mathcal{K}_4} \eta(S) < 0 \). Then, there exists a bad 4-clique \( S \) with \( \eta(S) < 0 \). Since a bad 4-clique \( S \) by Lemma 7.1(ii) must be heavy, that is, \( D(S) > 0 \), it is contained in some 5-clique. A 5-clique is called bad if it contains at least one bad 4-clique. We denote \( \mathcal{K}_5^{\text{bad}} \)
to be the set of bad 5-cliques. Define $\tilde{\eta}(S)$ to be $\eta(S)/D(S)$ for $S \in \mathcal{K}_4$ with $D(S) > 0$. Clearly,

$$n \sum_{S \in \mathcal{K}_4} \eta(S) = \sum_{U \in \mathcal{K}_5} \sum_{S \in \mathcal{K}_4(U)} \tilde{\eta}(S) + n \sum_{S \in \mathcal{K}_4, D(S) = 0} \eta(S).$$

(7.2)

Recall that our aim is to show that $\sum_{S \in \mathcal{K}_4} \eta(S) \geq 0$. Since $D(S) = 0$ implies that $S$ is good, we have $\eta(S) \geq 0$. Hence, it is enough to show that $\sum_{S \in \mathcal{K}_4(U)} \tilde{\eta}(S) \geq 0$ for each bad 5-clique $U$.

Now, we give a lower bound on $\tilde{\eta}(S)$ for bad 4-cliques $S$. By Lemma 7.1,

$$\eta(S) \geq -\frac{4\beta - 1}{29 - 75\beta} \sum_{T \in \mathcal{K}_4(S)} \frac{D_+(T)}{D_+(T) + \beta} \geq -\frac{2(4\beta - 1)}{29 - 75\beta} \frac{D(S)}{D(S) + \beta}.$$

Hence,

$$\tilde{\eta}(S) \geq -\frac{2(4\beta - 1)}{(29 - 75\beta)(D(S) + \beta)} > -\frac{2(4\beta - 1)}{(29 - 75\beta)\beta}.$$  

(7.3)

Next, we are going to bound $D(S)$ from above for $S \in \mathcal{K}_4(U) \backslash \mathcal{K}_4^{bad}$ and $U \in \mathcal{K}_5^{bad}$. Let $S^b \in \mathcal{K}_4^{bad}(U)$. Observe that $S \cap S^b$ is a 3-clique. Then, by Lemma 4.1 and Lemma 7.1, we have

$$D(S) \leq D(S \cap S^b) = D_+(S \cap S^b) + \beta \leq D(S^b) + \beta < \Delta + \beta.$$  

(7.4)

We claim that for each bad 5-clique $U \in \mathcal{K}_5^{bad}$

$$\sum_{S \in \mathcal{K}_4(U)} \tilde{\eta}(S) > 0.$$  

(7.5)

Recall that a bad 4-clique $S$ contains a heavy edge by Lemma 7.1(i), and hence so does a bad 5-clique $U$. We now divide into two cases depending on whether or not a bad 5-clique $U$ has two heavy edges.

**Case 1:** There are two heavy edges in $U$. Let $e$ and $e'$ be two heavy edges in $U$, and let $b$ be the number of bad 4-cliques in $U$. We consider separately the cases of whether or not $e$ and $e'$ are vertex-disjoint. First, assume that $e$ and $e'$ are vertex-disjoint. Notice that $\sum_{S \in \mathcal{K}_4^{bad}(U)} \tilde{\eta}(S) > -b\gamma$ by (7.3), where $\gamma = 2(4\beta - 1)/(29 - 75\beta)\beta$ and $b \leq 4$ by Lemma 7.2. Also, there is exactly one heavy 4-clique $S$ containing both $e$ and $e'$. Therefore, it is sufficient to prove that $\eta(S) \geq bD(S)\gamma$. Since $S$ contains two disjoint heavy edges, all triangles in $S$ are heavy by Lemma 4.1(iv). Thus, $\tilde{D}(S) = 2(4\beta - 1)$ by (7.1). Observe that $T = S \cap S'$ is a triangle for $S' \in \mathcal{K}_4(U) \backslash S$. Moreover, $D_+(T) \leq D_+(S') = D(S')$ by Lemma 4.1(iii). Hence,

$$\eta(S) \geq 2(4\beta - 1) - \frac{4\beta - 1}{29 - 75\beta} \sum_{S' \in \mathcal{K}_4(U), S} \frac{D(S')}{D(S') + \beta}$$

$$> (4\beta - 1) \left(2 - \frac{1}{29 - 75\beta} \left( b\Delta + \beta \right) \right)$$
by Lemma 7.1(ii) and (7.4). Therefore, \( \eta(S) - b D(S) \gamma \) is at least
\[
(4 \beta - 1) \left( 2 - \frac{1}{29 - 75 \beta} \left( \frac{b \Delta}{\Delta + \beta} + \frac{(4 - b)(\Delta + \beta)}{\Delta + 2 \beta} \right) \right) - b(\Delta + \beta) \gamma
\geq (4 \beta - 1) \left( 2 - \frac{4 \Delta}{(29 - 75 \beta)(\Delta + \beta)} \right) - 4(\Delta + \beta) \gamma > 0.
\]
Thus, if \( U \) contains two vertex-disjoint heavy edges, \( \sum_{S \in K_4(U)} \tilde{\eta}(S) > 0 \). A similar argument also holds for the case when \( e \) and \( e' \) share a common vertex.

**Case 2**: There is exactly one heavy edge in \( U \). Let \( u_1, \ldots, u_5 \) be the vertices of \( U \), where \( u_4 u_5 \) is the heavy edge. Write \( S_i \) and \( \eta_i \) to be \( U - u_i \) and \( \eta(S_i) \), respectively, for \( 1 \leq i \leq 5 \). Similarly, write \( T_{i,j} \) to be \( U - u_i - u_j \) for \( 1 \leq i < j \leq 5 \). Recall that a bad 4-clique contains a heavy edge by Lemma 7.1(i). Hence, \( S_i \) is a bad 4-clique only if \( i \leq 3 \). Without loss of generality, \( S_1, \ldots, S_b \) are the bad 4-cliques in \( U \).

Since \( S_3 \) contains a heavy edge, it contains at least two heavy triangles by Lemma 4.1(iv). If \( S_3 \) contains either three or four heavy triangles, then \( S_3 \) is not bad by Lemma 7.1(i). By an argument similar to that of Case 1, we can deduce that \( \eta_i \geq 2 \gamma D(S_i) \), where as before \( \gamma = 2(4 \beta - 1)/(29 - 75 \beta) \). Therefore, \( \sum_{S \in K_4(U)} \tilde{\eta}(S) > 0 \) as \( b \leq 2 \). Thus, we may assume that there are exactly two heavy triangles in \( S_i \) for \( 1 \leq i \leq 3 \). By Lemma 4.1(v), \( D(S_i) < \beta \) for \( 1 \leq i \leq b \).

\[
D(T_{i,4}) + D(T_{i,5}) < 2 \Delta = 2(1 - 3 \beta)(1 + \epsilon)
\]
by Lemma 7.1(iii). For \( b < i \leq 3 \), \( \tilde{D}(S_i) = D(T_{i,4}) + D(T_{i,5}) - 2(1 - 3 \beta) \) by (7.1). Thus,
\[
D(T_{i,4}) + D(T_{i,5}) = \eta_i + 2(1 - 3 \beta) + \frac{4 \beta - 1}{29 - 75 \beta} \sum_{T \in K_3(S_i)} \frac{D_+(T)}{D_+(T) + \beta}
\leq \eta_i + 2(1 - 3 \beta) + \frac{\gamma \beta D(S_i)}{D(S_i) + \beta}
\leq \eta_i + 2(1 - 3 \beta) + \gamma \beta / 2.
\]
After applying Corollary 4.5 to \( S_4 \) and \( S_5 \), taking \( t = 3 \), and adding the two inequalities together, we obtain
\[
2(2 - 4 \beta) \leq \sum_{1 \leq i \leq 3} (D_-(T_{i,4}) + D_-(T_{i,5})) + 2 D_-(T_{4,5})
\]
\[
2(2 - 5 \beta) \leq \sum_{1 \leq i \leq b} (D(T_{i,4}) + D(T_{i,5})) + \sum_{b < i \leq 3} (D(T_{i,4}) + D(T_{i,5}))
< 2b(1 - 3 \beta)(1 + \epsilon) + \sum_{b < i \leq 3} \eta_i + (3 - b)(2(1 - 3 \beta) + \gamma \beta / 2)
\]
\[
2(4 \beta - 1) < 2b(1 - 3 \beta) \epsilon + \sum_{b < i \leq 3} \eta_i + (3 - b) \gamma \beta / 2.
\]
(7.6)
If \( b = 3 \), the inequality above becomes
\[
2(4 \beta - 1) < 6(1 - 3 \beta) \epsilon < 2(4 \beta - 1),
\]
which is a contradiction. Thus, \( b \leq 2 \). Notice that \( \eta_i > -D(S)i^\gamma > -\gamma \) for \( 1 \leq i \leq b \). Hence, 
\[ \sum_{S \in K_4} \tilde{\eta}(S) > -b^\gamma. \]
Also, recall that \( D(S) \leq \beta \) for \( 1 \leq i \leq 3 \). It is enough to show that 
\[ \sum_{b < i \leq 3} \eta_i \geq b\gamma. \]
Suppose the contrary, so \( \sum_{b < i \leq 3} \eta_i < b\gamma. \) Then, (7.6) becomes
\[ 2(4\beta - 1) < 2b(1 - 3\beta)e + (3 + b)\gamma/2 \leq 4(1 - 3\beta)e + 5\gamma/2 < 2(4\beta - 1), \]
which is a contradiction.

Therefore, (7.5) holds as claimed, so the inequality in Lemma 6.3 holds as \( \sum_{S \in K_4} \eta(S) \geq 0 \) by (7.2). Now suppose equality holds in Lemma 6.3, i.e., \( \sum_{S \in K_4} \eta(S) = 0 \). By (7.2) and (7.5), no 5-clique is bad and so no 4-clique is bad. Furthermore, we must have \( \eta(S) = 0 \) for all \( S \in K_4 \). It can be checked that if the definition of a bad 4-clique includes heavy 4-cliques \( S \) with \( \eta(S) = 0 \), then all arguments still hold. Thus, we can deduce that \( G \) is \( K_5 \)-free. Hence, \( G \) is also \( K_5 \)-free. By Theorem 5.1, taking \( s = 4 \) and \( t = 3 \), we obtain that \( (n, \beta) \) is feasible and \( G \in G(n, \beta) \).

\[ \square \]

8. Proof of Theorem 2.4

Our aim is to prove Theorem 2.4. First, we strengthen Corollary 4.5 by mimicking the proof of Lemma 6.1. Then, we follow the proof of Theorem 5.1 using the strengthened version of Corollary 4.5. Hence, we only give a sketch of the proof of Theorem 2.4 to avoid getting bogged down by the details.

**Sketch of Proof of Theorem 2.4.** For \( 2 \leq t \leq p \) and \( 1/(p + 1) \leq \beta < 1/p \), define
\[ A_t^p(\beta) = (t - 1)((p + 1)\beta - 1)C_t^p(\beta), \]
\[ B_t^p(\beta) = ((p + 1)\beta - 1)C_t^p(\beta), \]
where \( C_j(\beta) \) satisfies the recurrence
\[ C_t(\beta) + 1 = (p - t + 1)\beta C_{t-1}(\beta) \]
with the initial condition \( C_p(\beta) = 0 \) for \( 1/(p + 1) \leq \beta < 1/p \). Explicitly, \( C_{p-j}(\beta) = \sum_{0 \leq i < j} \frac{1}{i!} \beta^{i-j}/j! \) for \( 0 \leq j \leq p - 2 \). These functions will be used as coefficients in corresponding statements of Lemma 6.1 for \( 2 \leq t < p \). Define the integer \( r(\beta) \) to be the smallest integer at least 2 such that, for \( r \leq t \leq p \), \( A_t^p(\beta) < 1 \) and \( B_t^p(\beta) < (p - t)\beta \). Let
\[ \beta_p = \sup\{ \beta_0 : r(\beta) = 2 \text{ for all } 1/(p + 1) \leq \beta < \beta_0 \} \]
and \( \epsilon_p = \beta_p - 1/(p + 1) \). Observe that \( A_t(\beta), B_t(\beta) \) and \( C_t(\beta) \) are right continuous functions of \( \beta \). Moreover, both \( A_t(\beta) \) and \( B_t(\beta) \) tend to zero as \( \beta \) tends to \( 1/(p + 1) \) from above, so \( \beta_p > 1/(p + 1) \) and \( \epsilon_p > 0 \). By mimicking the proof of Lemma 6.1, we have
\[ \bar{D}(S) \geq A_{t+1}^p(\beta)D_+(S) - B_t^p(\beta) \sum_{T \in K_4(S)} \frac{D_+(T)}{D(T)} \]
(8.1)
for \( S \in K_{t+1}, 1/(p + 1) \leq \beta < \beta_p \) and \( 2 \leq t \leq p \). Note that (8.1) is a strengthening of Corollary 4.5. Then, following the arguments in the proof of Theorem 5.1 while using
Let Lemma 9.2. for \( s \) would lead to an improvement on \( \epsilon_p \) so \( \Phi \in S \). Let Theorem 9.1. In this section, we are going to prove the following theorem, which implies Theorem 2.5.

(8.1) instead of Corollary 4.5, we can deduce that

\[
\frac{k_i(G)}{g_i(\beta)n^t} \geq \frac{1 - t\beta - B_p^i(\beta)}{(1 - t\beta)(p - t + 1)\beta g_i(\beta)n^t} \sum_{T \in K_t} D_+(T)
\]

for \( 2 \leq t < s \leq p + 1 \) and \( 1/(p + 1) < \beta \leq \beta_p \). Since \( 1 - t\beta - B_p^i(\beta) \geq 0 \), the proof of the theorem is completed.

Clearly, \( \epsilon_p \) defined in the proof is not optimal. Generalizing the proof of Lemma 6.3 would lead to an improvement on \( \epsilon_p \).

9. Counting \((p + 1)\)-cliques

In this section, we are going to prove the following theorem, which implies Theorem 2.5.

**Theorem 9.1.** Let \( 0 < \beta < 1 \) and \( p = [\beta^{-1}] - 1 \). Suppose \( G \) is a graph of order \( n \) with minimum degree \( (1 - \beta)n \). Then, for any integer \( 2 \leq t \leq p \),

\[
\frac{k_{p+1}(G)}{g_{p+1}(\beta)n^{p+1}} \geq \frac{k_i(G)}{g_i(\beta)n^t}.
\]

Moreover, for \( t = 2 \), equality holds if and only if \((n, \beta)\) is feasible, and \( G \) is a member of \( \mathcal{G}(n, \beta) \).

For positive integers \( 2 \leq t \leq s \leq p + 1 \), define the function \( \phi^s_t : K_s \to \mathbb{R} \) such that

\[
\phi^s_t(S) = \begin{cases} 
D_-(S) & \text{if } t = s, \\
\sum_{U \in K_{s-1}(S)} \phi^{s-1}_t(U) & \text{if } t < s,
\end{cases}
\]

for \( S \in K_s \). Observe that for \( G_0 \in \mathcal{G}(n, \beta) \) with \((n, \beta)\) feasible,

\[
\phi^s_t(S) = \begin{cases} 
(s-t)!(1-t\beta) & \text{if } |V(S) \cap V_0| = 0, 1, \\
(1-t\beta)s!/t! + ((p+1)(p+1)(p+1)-(s-2)!)/(t-2)! & \text{if } |V(S) \cap V_0| = 2,
\end{cases}
\]

for \( s \)-cliques \( S \) in \( G_0 \). Let \( \Phi^s_t(S) = \min\{\phi^s_t(S), \phi^t_t\} \) for \( S \in K_s \) and \( 2 \leq t \leq s \leq p + 1 \), where

\[
\phi^s_t = (1-t\beta)s!/t! + ((p+1)(p+1)(p+1)-(s-2)!)/(t-2)!,
\]

so \( \Phi^s_t(S) \) is the analogue of \( D_- \) for \( \phi^s_t \). The next lemma gives a lower bound on \( \Phi^s_t(S) \) for \( S \in K_s \).

**Lemma 9.2.** Let \( 0 < \beta < 1 \) and \( p = [\beta^{-1}] - 1 \). Let \( G \) be a graph of order \( n \) with minimum degree \( (1 - \beta)n \). Then,

\[
\Phi^s_t(S) \geq (1-t\beta)s!/t! + (D_- - (1-s\beta)) (s-2)!/(t-2)!
\]

for \( S \in K_s \) and \( 2 \leq t < s \leq p + 1 \). In particular, for \( s = p + 1 \) and \( t = p \),

\[
\sum_{S \in K_{p+1}} \Phi^{p+1}_t(S) \geq \left( (1-t\beta) \frac{(p+1)!}{t!} - (1-(p+1)(p+1)(p+1)) \frac{(p-1)!}{(t-2)!} \right) k_{p+1}.
\]
Proof. Fix $\beta$ and $t$ and we proceed by induction on $s$. The inequality holds for $s = t + 1$ by Corollary 4.5. Suppose $s \geq t + 2$ and that the lemma is true for $t, \ldots, s - 1$. Hence

$$\phi_s^t(S) = \sum_{T \in K_{s-1}(S)} \phi_s^{t-1}(T) \geq \sum_{T \in K_{s-1}(S)} \Phi_s^{t-1}(T)$$

$$\geq \sum_{T \in K_{s-1}(S)} \left( (1 - t\beta) \frac{(s-1)!}{t!} + (D_-(T) - (1 - (s-1)\beta)) \frac{(s-3)!}{(t-2)!} \right)$$

$$= (1 - t\beta) \frac{s!}{t!} + \frac{(s-3)!}{(t-2)!} \left( \sum_{T \in K_{s-1}(S)} D_-(T) - s(1 - (s-1)\beta) \right)$$

$$\geq (1 - t\beta) \frac{s!}{t!} + (D_-(S) - (1 - s\beta))(s-2)!/(t-2)!,$$

by the induction hypothesis in the second line, and where the last inequality comes from Corollary 4.5 with $t = s - 1$. The right-hand side is increasing in $D_-(S)$. In addition, the right-hand side equals $\phi_s^t$ only if $D_-(S) = (p - s + 1)\beta$. Thus, the proof of the lemma is complete.

Now, we bound $\sum_{S \in K_T} \Phi_i(S)$ from above using Proposition 3.1 to obtain the next lemma. The proof is essentially a straightforward application of Proposition 3.1 with an algebraic check.

Lemma 9.3. Let $0 < \beta < 1$ and $p = \lceil \beta^{-1} \rceil - 1$. Let $G$ be a graph of order $n$ with minimum degree $(1 - \beta)n$. Then, for $2 \leq t \leq s \leq p + 1$,

$$\sum_{S \in K_T} \Phi_i(S) \leq \phi_i^{s-1} s k_s + 2((p + 1)\beta - 1) \sum_{i=t+1}^{s-1} \frac{(i-3)!}{(t-2)!} k_i n^{s-i} \prod_{j=i}^{s-1} (1 - j\beta)$$

$$+ ((t+1)k_{t+1} - (p - t + 1)\beta k_t n) n^{s-t-1} \prod_{j=t}^{s-1} (1 - j\beta).$$

Proof. Fix $\beta$ and $t$. We proceed by induction on $s$. Suppose $s = t + 1$. Note that $\Phi_i^{t+1}(S) \leq \sum_{T \in K_{s-1}(S)} D_-(T)$. By Proposition 3.1, taking $A = K_t, f = D_-, g = D, M = (p - t + 1)\beta$ and $m = 1 - t\beta$,

$$\sum_{S \in K_{t+1}} \Phi_i^{t+1}(S) \leq \sum_{S \in K_{t+1}} \sum_{T \in K_{s-1}(S)} D_-(T) = n \sum_{T \in K_t} D(T) D_-(T)$$

$$\leq (p - t + 1)\beta n \sum_{T \in K_t} D(T) + (1 - t\beta) n \sum_{T \in K_t} D_-(T) - (1 - t\beta)(p - t + 1)\beta n k_t$$

$$\leq (t+1)(1 - (p - 2t + 1)\beta) k_{t+1} - (1 - t\beta)(p - t + 1)\beta n k_t.$$

Hence, the lemma is true for $s = t + 1$. Now assume that $s \geq t + 2$ and the lemma is true up to $s - 1$. By Proposition 3.1, taking $A = K_t, f = \Phi_i^{s-1}, g = D, M = \phi_i^{s-1}$ and
\[ m = 1 - (s - 1)\beta, \text{ we have} \]
\[ \sum_{S \in \mathcal{K}_s} \Phi_t^s(S) = n \sum_{T \in \mathcal{K}_{s-1}} D(T) \Phi_t^{s-1}(T) \]
\[ \leq \phi_t^{s-1} \sum_{T \in \mathcal{K}_{s-1}} nD(T) + (1 - (s - 1)\beta)n \sum_{T \in \mathcal{K}_{s-1}} \Phi_t^{s-1}(T) - \phi_t^{s-1}(1 - (s - 1)\beta)nk_{s-1} \]
\[ = \phi_t^{s-1}sk_s + (1 - (s - 1)\beta)n \sum_{T \in \mathcal{K}_{s-1}} \Phi_t^{s-1}(T) - \phi_t^{s-1}(1 - (s - 1)\beta)nk_{s-1}. \]

Next, we apply the induction hypothesis on \( \sum \Phi_t^{s-1}(T) \). Note that
\[ (s - 1)\phi_t^{s-2} - \phi_t^{s-1} = 2((p + 1)\beta - 1)(s - 4)!/(t - 2)!. \]

After collecting the terms, we obtain the desired inequality. \( \square \)

Now we are ready to prove Theorem 9.1. The proof is very similar to the proof of Theorem 5.1.

**Proof of Theorem 9.1.** We fix \( \beta \) and write \( g_t \) for \( g_t(\beta) \). We proceed by induction on \( t \) from above. The theorem is true for \( t = p \) by Lemma 9.2 and Lemma 9.3. Hence, we may assume \( t < p \). By Lemma 9.3,
\[ \sum \Phi_t^{p+1}(S) \leq (p + 1)\phi_t^{p}k_{p+1} + 2((p + 1)\beta - 1) \sum_{i=t+1}^{p} \left( \frac{(i - 3)!}{(t - 2)!} k_{i}n^{p+1-i} \prod_{j=i}^{p}(1 - j\beta) \right) \]
\[ + \left( (t + 1)k_{t+1} - (p - t + 1)\beta nk_{t} \right) n^{p-t} \prod_{j=t}^{p}(1 - j\beta), \]
\[ \leq (p + 1)\phi_t^{p}k_{p+1} + 2((p + 1)\beta - 1) \sum_{i=t+1}^{p} \left( \frac{k_{p+1}g_{i}}{g_{p+1}} \frac{(i - 3)!}{(t - 2)!} \prod_{j=i}^{p}(1 - j\beta) \right) \]
\[ + \left( (t + 1)\frac{k_{p+1}}{g_{p+1}} g_{t+1} - (p - t + 1)\beta nk_{t} \right) n^{p-t} \prod_{j=t}^{p}(1 - j\beta). \]

by the induction hypothesis for the second inequality. Substitute the inequality above into (9.1) and rearrange, to obtain the desired inequality.

Now suppose that equality holds, so equality holds in (9.1). Therefore, \( D(S) = D_-(S) = 0 \) for all \( S \in \mathcal{K}_{p+1} \). Thus, \( G \) is \( K_{p+2} \)-free. By Theorem 5.1, \((n, \beta)\) is feasible, and \( G \in G(n, \beta) \). This completes the proof of the theorem. \( \square \)
