Abstract
Form factors for pions interactions with constituent quarks are investigated as the leading effective couplings obtained from a one loop background field method applied to a global color model. Two pion field definitions are considered and the resulting eleven form factors are expressed in terms of components of the quark and gluon propagators that compose only two momentum dependent functions. A momentum dependent Goldberger Treiman relation is also obtained as one of the ratios between the form factors. The resulting form factors with pion momenta up to 1.5 GeV are exhibited for different quark effective masses and two different nonperturbative gluon propagators and they present similar behavior to fittings of experimental data from nucleons form factors. The corresponding pseudoscalar averaged quadratic radii (a.q.r.) and correction to the axial a.q.r. are presented as functions of the sea quark effective mass, being equal respectively to the scalar and vector ones at the present level of calculation.

1 Introduction
Strong, electromagnetic and weak content of hadrons have been under continuous intense theoretical and experimental scrutiny. Different hadrons form factors are among the main observables for understanding details of their interactions and structures, including sizes, and they are important quantities to compare theoretical and experimental results [1, 2, 3, 4, 5]. For example, the vector form factors provide the charge and electromagnetic hadron structure and interactions, the nucleon axial form factor provides important information for their spin structure and weak interaction observables such as neutron beta decay or CKM matrix unitarity. There are many theoretical calculations for the light hadrons strong form factors, for example [6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17] and references therein. Lately, lattice estimations for pion- nucleon/baryons interactions were provided for progressively lower values of the pion mass, for example in [17, 18]. Concerning their very low momentum behavior, experimental results for nucleon electromagnetic and strong averaged radii provide values $\sqrt{\langle r^2 \rangle} \approx 0.8 - 0.9$ fm [19, 20, 1, 13].

In spite of the many difficulties to provide a complete description of hadrons and their interactions compatible with experimental data directly from QCD, in particular in the low and intermediary energies regimes, both effective models and effective theories have been considered to understand partial or isolated aspects of Strong Interactions. Among these models the constituent quark models (CQM) has shown to describe many aspects of hadron structure and interactions by considering dressed quark degrees of freedom, Dynamical Chiral Symmetry Breaking (DChSB) and eventually a pion cloud, [21, 22, 23, 12]. Within the constituent quark model it has been argued that the zero momentum limit of the axial form factor should be $g_A(0) = 3/4$ or $g_A(0) = 1$ [12, 21]. Also, a radius of the order of 0.2 – 0.3 fm has been estimated for constituent quarks [12, 24]. In the Weinberg’s large Nc Effective Field Theory (EFT) constituent quarks and gluons interact with pions whose dynamics is ruled by the leading terms of Chiral Perturbation Theory (ChPT), coping with the large Nc expansion [21]. In [25, 26] this EFT has been derived as the leading terms from a large quark and gluon effective masses expansion for the one loop background field method applied to a global color model in the vacuum and with leading couplings to the electromagnetic field. It can be expected that, by comparing the strong and electromagnetic nucleon and light mesons form factors with those for constituent quarks, the detailed role and contribution of each internal degree of freedom for the details of hadron structure and interactions might be elucidated clearly. Of course, to accomplish this program, besides further comparisons between different theoretical frameworks, it is also important to improve the amount and precision of experimental data. This means that the related developments might shed light on the partial or even complete reliability of CQM-type models to describe hadron interactions in particular energy ranges. Moreover, these comparisons might make explicit particular effects or mechanisms present in hadrons structure and interactions by means of analytical or semi-analytical approaches besides well established lattice QCD framework. Eventually it can be used to assess or to improve field theoretic schemes for an eventual unambiguous parameterization of the nucleon and nuclear potentials [27].

In the present work the strong constituent quark form factors associated to the leading pion couplings to constituent quarks are derived and investigated. This method was considered before for the zero momentum limit of
the corresponding pion-constituent quark couplings \cite{28,29} and for the light vector mesons momentum dependent
couplings to constituent quarks \cite{25,26}. The form factors are obtained from a large quark and gluon effective masses
expansion for the one loop background field applied to a global color model. The background field quark becomes
the constituent quark due to the one loop calculation in which an internal (non perturbative) gluon line dresses the
(background) quark This is nearly independent from the dynamical symmetry breaking, except for the fact that
the same gluon propagator required to yield DChSB is considered. This momentum dependent constituent quark
mass emerges therefore by means of a different mechanism from the usual DChSB. This might be in agreement with
recent calculations \cite{30}. The resulting couplings and form factors therefore correspond to tree level pion-constituent
quark vertices. These pion-constituent quarks form factors are investigated and comparisons with experimental data
for pion nucleon are presented. Furthermore four further pion derivative couplings with scalar and pseudoscalar
constituent quark currents that emerge at the same leading terms of the determinant expansion are also presented.
They might contribute to the vector and axial channels. Direct and simple momentum dependent and independent
relations between different form factors are also presented. In particular one relation corresponds to a generalized
momentum dependent Goldberger Treiman relation (GTR). Besides that the corresponding strong radii
of constituent quarks (scalar, pseudoscalar, vector and axial) are also presented as functions of the quark effective
mass. The axial (and vector) pion coupling presented in this work provides a further contribution for the corre-
sponding axial (and vector) form factors and quadratic radii to those calculated in \cite{28}. Two pion field definitions
are considered, the Weinberg pion field, in terms of covariant derivatives, and the usual parameterization in terms
of the operators \( U = e^{i \vec{p} \cdot \vec{\sigma}} \). The conventional definition in terms of the functions \( U = e^{i \vec{\sigma} \cdot \vec{x}} \) provides the well known pseudoscalar pion coupling that is not found in the Weinberg pion field case. The isospin non degeneracy of up-down
quark masses is not considered in this work since it should be responsible for smaller (higher order) effects. This work
is organized as follows. In the next Section the steps of the method are briefly reminded and the large quark effective
mass expansion of a sea quark determinant is performed. By keeping the full momentum dependence of the resulting
constituent quark - pion couplings the corresponding form factors are presented for the two definitions of the pion field
in the following section. Due to the momentum structure of some of the form factors it is also convenient to perform
a truncation that provides, latter, corresponding positive averaged quadratic radii. All the eleven form factors, five
for the Weinberg pion field and six for the second pion field definition, are written in terms of only two momentum
dependent functions, denoted \( F_1(K, Q) \) and \( F_2(K, Q) \). Besides that, the momentum dependent constituent quark
mass correction, \( M_3(Q) \) is investigated. In the following Section numerical results are exhibited for different values
of quark effective mass and for two very different gluon propagators: an effective longitudinal confining propagator
considered by Cornwall \cite{31} and a transversal one used extensively and successfully to provide hadron observables by
Tandy and Maris \cite{82}. Some ratios and comparisons of the form factors are also presented including the estimation
of a momentum dependent Goldberger Treiman relation. The corresponding contributions for the pseudoscalar and
axial strong constituent quark quadratic radii are also investigated as a functions of the quark effective mass for the
different gluon propagators. In the last Section a summary is presented.

\section{The quark determinant, pions and constituent quark currents}

Consider the non perturbative one gluon exchange quark-quark interaction as one of the leading terms of QCD
effective action whose generating functional is given by \cite{33,34}:

\[ Z = N \int \mathcal{D}[\bar{\psi}, \psi] \exp i \int \left[ \bar{\psi} \left( i \gamma \sigma - m \right) \psi - \frac{g^2}{2} \int \frac{dx}{y} \bar{J}_y \left( x - y \right) \phi \left( x - y \right) + \bar{\psi} J \psi \right] \]

(1)

Where \( N \) is the normalization, \( J, J^* \) the quark sources, \( \int \frac{dx}{y} \) stands for \( \int d^4x \) and \( a, b, \ldots = 1, \ldots (N_f^2 - 1) \) stands
for color in the adjoint representation being \( N_c = 3 \). The functional measure for the quark field was written
as \( \mathcal{D}[\bar{\psi}, \psi] = \mathcal{D}[\bar{\psi}] \mathcal{D}[\psi] \). The quark gluon coupling constant is assumed to be \( g \) and the development below is
akin to the Rainbow Ladder Schwinger Dyson equation (SDE). Below indices \( i, j, k = 0, \ldots (N_f^2 - 1) \) will be used
for SU(2) isospin indices and therefore \( N_f = 2 \). The quark current mass will be assumed to be equal for u, d
quarks. The color quark currents are given by \( j_a^\mu = \bar{\psi} \lambda^a \gamma^\mu \psi \), and the sums in color, flavor and Dirac indices
are implicit. A Landau-type gauge will be considered for a non perturbative gluon propagator that can be written
as \( R_{\mu \nu}^{ab} \left( x - y \right) \equiv \bar{R}_{\mu \nu}^{ab} = \delta^{ab} \left[ \left( g^{\mu \nu} - \frac{2 g^\mu g^\nu}{4} \right) R_T \left( x - y \right) + \frac{g^\mu g^\nu}{4} R_L \left( x - y \right) \right] \), where the transversal and longitudinal components are \( R_T \left( x - y \right) \) and \( R_L \left( x - y \right) \). This non perturbative gluon kernel therefore incorporates to some extent
the gluonic non Abelian character with a corrected quark-gluon coupling such that they will provide enough strength
to yield dynamical chiral symmetry breaking (DChSB). This has been found in several approaches and extensions
of DChSB. The method was explained in details in Refs. \cite{10,25,26,28,29} and therefore it will be succinctly described
below. A Fierz transformation for the model \cite{1} is performed and, by picking up the leading color singlet terms
that provide the usual pion couplings, it allows to investigate the flavor structure in a more complete way. Besides
that, color singlets, in one hand, avoid problems with unconfined spurious color degrees of freedom and, on the other
hand, provides a direct relation with quark-antiquark lightest observed states. These states are to be identified with the light hadrons degrees of freedom and the scalar chiral condensate by means of the corresponding fields to be introduced. Chiral structures with combinations of bilocal currents are obtained. The quark field must be responsible for the formation of mesons and baryons and these different possibilities are envisaged by considering the Background Field Method (BFM) [41, 42]. Therefore we consider the quark field is splitted into sea quark, $\psi_2$, composing (light) quark-antiquark states including light mesons and the chiral condensate, and the (constituent) background quark, $\psi_1$, to compose baryons. The shift of quark bilinears corresponds to performing a one loop BFM calculation and it might be written for each of the color singlet Dirac/isospin channels $m = s, p, si, pi, ps, v, a, as, vs$ (scalar, pseudoscalar, scalar-isospin triplet, pseudoscalar-isospin triplet, vector, axial, vector-isospin triplet, axial-isospin triplet, where the isospin singlet states were omitted). Each of these channels might have a corresponding auxiliary field. However only the lightest pseudoscalar-isotriplet and isoscalar-scalar degrees of freedom will be investigated in the present work. The quark field shift is of the following form:

$$j^m = \bar{\psi}\Gamma^m\psi \rightarrow (\bar{\psi}\Gamma^m\psi)_2 + (\bar{\psi}\Gamma^m\psi)_1.$$  \hspace{1cm} (2)

This separation preserves chiral symmetry. The sea quark can be integrated out exactly by means of the auxiliary field method that give rise to colorless quark-antiquark states, light mesons and the chiral quark condensate. Auxiliary fields are introduced by means of the unity integrals multiplying the generating functional. The only degrees of freedom considered in this work are the chiral scalar and pseudoscalar-iso-triplet ones which are needed for the pion sector in the leading order. The heavier vector and axial mesons can be neglected in the lower energy regime. Therefore one will be left with a model for pions and a scalar field interacting with constituent quarks. The corresponding unity integral for the scalar and pseudoscalar auxiliary bilocal fields $S(x, y), P_i(x, y)$ is the following:

$$1 = \frac{N''}{\Xi} \int [D[S]D[P]\varepsilon^{-\frac{1}{2}} \sum_\alpha R(x-y)^\alpha (S-g_s^2\alpha^2 + (P_i-g_s^2\alpha^2)^2)},$$  \hspace{1cm} (3)

where $N''$ is a normalization, and

$$R(x-y) = 3R_T(y) + R_L(x-y).$$  \hspace{1cm} (4)

Bilocal auxiliary fields for the different flavors can be expanded in an infinite orthogonal basis with all the excitations in the corresponding channel. For the pseudoscalar isotriplet fields one has:

$$P_i(x, y) = P_i(\frac{x+y}{2}, x-y) = P_i(u, z) = \sum_k F_k(z)P_{i,k}(u),$$  \hspace{1cm} (5)

where $F_k$ are vacuum functions invariant under translation for each of the local field $P_{i,k}(u)$. For the low energy regime one might pick up only the lowest energy modes, highest $k = 0$ which corresponds to the pions in this channel, i.e. $P_{i,k=0} = \pi_i$, making the form factors to reduce to constants in the zero momentum limit $F_k(z) = F_k(0)$. The saddle point equations for each of the remaining auxiliary fields, after the integration of the sea quark, can be written from the condition: $\frac{\partial S_{str}}{\partial P_{i,k}} = 0$. These equations for the NJL model and for the model [41] with Schwinger Dyson equations at the rainbow ladder level have been analyzed in many works in the vacuum or under a finite energy density. The scalar field has the only saddle point equation with non trivial solution for the quark-antiquark chiral condensate. This classical solution generates an effective mass for sea quarks. Chiral symmetry leaves a freedom to define the pion field and chiral rotations can be done to modify its definition. The scalar field can be frozen by means of a chiral rotation and this produces the chiral condensate and a strongly non linear pion sector. An usual pion field definition is parameterized by the functions:

$$\exp\{i\vec{\pi} \cdot \vec{\sigma}\}$$ and $U^{1} = \exp\{-i\vec{\pi} \cdot \vec{\sigma}\}$. To investigate this aspect another pion field definition, the Weinberg ones, is characterized by writing all the chiral invariant sector in terms of a covariant pion derivative given by:

$$\mathcal{D}_\mu \pi_i = \frac{\partial_\mu \pi_i}{1 + \vec{\pi} \cdot \vec{\sigma}}.$$  \hspace{1cm} (6)

The chiral symmetry breaking terms however can depend on combinations of $\vec{\pi}$ and $\vec{\pi}^2$. By doing the corresponding chiral rotations particular set of constituent quark-pion interactions are obtained. The corresponding Jacobian of the path integral measure will not be calculated and it might induce extra terms for the resulting form factors.

By performing a Gaussian integration of the sea quark field, the resulting determinant can be written, by means of the identity $\det A = \exp TR \ln(\det A)$, as:

$$S_{\text{eff}} = -i \ln\{S^{-1}_q(x-y)\},$$  \hspace{1cm} (7)

$$S_q^{-1}(x-y) \equiv S_q^{-1}(x-y) + \Xi_q(x-y) + \sum_q a_q\Gamma_q j_q(x, y),$$  \hspace{1cm} (8)
where $\text{Tr}$ stands for traces of all discrete internal indices and integration of spacetime coordinates and $\Xi_s(x-y)$ stands for the coupling of sea quark to the scalar-pseudoscalar fields for a particular pion field. This coupling term can be written respectively for the Weinberg pion field ($\Xi^W_s(x-y)$) and for the usual pion field ($\Xi^U_s(x-y)$) in terms of unitary functions $U, U^\dagger$ as [25, 26]:

$$\Xi^W_s(x-y) = \left[ \gamma^\nu \partial_\nu \pi \gamma_5 i + i\gamma^\nu \partial_\nu \pi \gamma_5 \partial_\mu \pi \gamma_5 \partial_\nu \pi \gamma_5 \partial_\mu \pi \gamma_5 \right] \delta(x-y),$$

$$\Xi^U_s(x-y) = F(P_R U + P_L U^\dagger) \delta(x-y),$$

where $F = f_\pi$ is the pion field normalization, $P_R/L = (\mp \gamma_5)/2$ are the chirality right/left hand projectors.

The free quark kernel can be written as $S_0^{-1}(x-y) = (i\slashed{\partial} - m) \delta(x-y)$, where $m$ is so far the current quark mass. The classical solution for the scalar field, found from its gap equation, is directly incorporated into an effective quark mass $M^* = m - <s>$. The redefined quark kernel can be written as:

$$S_0^{-1}(x-y) = (i\slashed{\partial} - M^*) \delta(x-y).$$

In expression (8) the following quantity, with the usual chiral constituent quark currents that yield the leading couplings to pions, has been used:

$$\sum_q a_q \Gamma_q j_q(x,y) \alpha g^2 = 2R(x-y) \left[ \bar{\psi}(y)\psi(x) + i\gamma_5 \sigma_i \bar{\psi}(y)i\gamma_5 \sigma_i \psi(x) \right] - R^{\mu\nu}(x-y) \gamma_\mu \sigma_i \left[ \bar{\psi}(y)\gamma_\nu \sigma_i \psi(x) + \gamma_5 \bar{\psi}(y)\gamma_5 \gamma_\nu \sigma_i \psi(x) \right].$$

In this expression, $\alpha = 2/9$ from the Fierz transformation, $R(x-y)$ was given in [4] and

$$R^{\mu\nu}(x-y) = g^{\mu\nu}(R_T(x-y) + R_L(x-y)) + 2\frac{\partial^{\mu\nu}}{\partial^2}(R_T(x-y) - R_L(x-y)).$$

### 3 Leading form Factors

In the following, consider the quark (and gluon) large effective mass expansion for the case in which quark and pion fields exchange momenta. To provide the reader with one example, one of the leading pion constituent quark effective interactions is the pseudoscalar coupling and it shows up in the first order terms of the expansion as it follows:

$$I_{ps}^{s} = \frac{i}{2} \text{Tr} \left[ S_0(y-x)i\gamma_5 \sigma_i i\gamma_5 \sigma_i \pi_i(x)S_0(x-z)R(y-z)i\gamma_5 \sigma_j \bar{\psi}(z)i\gamma_5 \sigma_j \psi(y) \right].$$

With the insertion of complete sets of orthogonal momentum states, a pseudoscalar form factor at the constituent quark level emerges in momentum space, $G_p^{ps}(K,Q)$, where the momenta $K,Q$ are defined below. For this, the trace in internal indices (isospin, color and Dirac) were calculated. By considering incoming quark with momentum $K$, and pion(s) with total momenta $Q$ the set of leading momentum dependent effective couplings for the first pion definition (W) in the weak pion field limit $(1 + \pi^2 \approx 1)$ is given by:

$$\mathcal{L}_{\psi}^{W} = M_3(K) \bar{\psi}(K)\gamma_\mu \psi(K) + 2i\epsilon_{ijk}G_p^{W}(K,Q)\pi_i(q_u)\partial^{\mu}\pi_j(q_u) \bar{\psi}(K)\gamma_\nu a^5 \psi(K + Q) + 2G_{\beta\beta F}^{W}(K,Q)\bar{\psi}(K)\gamma_\nu a^5 \psi(K + Q) + Fg_{\beta\beta F}(K,Q) \bar{\psi}(K)\gamma_\nu a^5 \psi(K + Q) - G_p^{W}(K,Q) \bar{\psi}(K)\gamma_\nu a^5 \psi(K + Q) - G_p^{W}(K,Q) \bar{\psi}(K)\gamma_\nu a^5 \psi(K + Q) + \frac{\partial^{\mu\nu}}{\partial^2}(Q) \bar{\psi}(K)\gamma_\nu a^5 \psi(K + Q),$$

where $Q = Q_\pi$ is the total momentum carried by one or two pion in each of the vertices, and it will be for both pion field definitions $W$ and $U$, being that, in the vector and scalar constituent quark currents couplings, $Q = q_u + q_b$ and the pion field was kept dimensionless. The last two terms, momentum dependent ones, were obtained with an integration by parts. In this expression $M_3(K)$ is a running effective mass that will be defined below in [23], and the following dimensionless form factors were defined in terms of the functions $F_1(K,Q)$ given below:

$$G_p^{W}(K,Q) = G_p^{W}(K,Q) = 4d_1N_c(a g^2)^2 F_1(K,Q)$$

$$G_{\beta\beta F}(K,Q) = 64d_1N_c \frac{m}{F}(a g^2)^2 F_1(K,Q),$$

$$G_p^{W}(K,Q) = \frac{M^*}{4m} G_p^{W}(K,Q) = 16d_1 M^* N_c (a g^2)^2 F_2(K,Q)$$

where $N_c = 3, d_n = (-1)^{n+1}/(2n)$. It is interesting to note that the scalar pion coupling is proportional to the current quark mass and therefore it is a consequence of explicit chiral symmetry breaking. There are a scalar and
and pion is represented by dashed lines. In diagrams (1a-c) the incoming constituent has momentum $(19)$ with the same conventions of Figure 1. This truncation might be expected to correspond to making an effective mass $M_3(\bar{Q})$ that might contribute for the vector channel.

The complete set of leading momentum dependent couplings with their form factors for the second pion definition, with the same convention for momenta of expression (15) and dimensionless pion field, is given by:

$$\mathcal{L}^{\pi} - \pi = M_3(K) \bar{\psi}(K)\psi(K) + G_{2j_2s}(K, Q) F_{\pi_i}(q_a)\pi_i(q_b)\bar{\psi}(K)\psi(K + Q)$$

$$+ G'_{ps}(K, Q) F_{\pi_i}(q_a) \bar{\psi}(K)\sigma_i\gamma_5\psi(K + Q)$$

$$+ i\epsilon_{ijk} 2 G'_{V}(K, Q) \bar{\psi}(K)\pi_i(q_b) (\partial_\mu\pi_j(q_b)) \psi(K)\gamma_\mu\sigma^j\psi(K + Q),$$

$$+ 2 G'_{A}(K, Q) (\partial^\mu\pi_i(q_b)) \bar{\psi}(K)\gamma_\mu\gamma_5\gamma_\tau\sigma^\tau\psi(K + Q)$$

$$- G'_{ps}(K, Q) \frac{(\partial^2\pi_i(q_b))}{M^*} \bar{\psi}(K)\sigma_i\gamma_5\psi(K + Q) - G'_g(K, Q) \frac{(\partial^2\pi_i(q_b))}{M^*} \bar{\psi}(K)\psi(K + Q),$$

where $M_3(K)$ is the same as the mass in expression (15) and it will be defined in expression (23). The other form factors were defined as:

$$G_{ps}^v(K, Q) = G_{2j_2s}(K, Q) = 32d_1N_c(\alpha g^2) F_1(K, Q),$$

$$G'_{A}(K, Q) = G'_{ps}^v(K, Q) = 16d_1N_c F (\alpha g^2) F_2(K, Q),$$

$$G'_{ps}(K, Q) = G'_{ps}^s(K, Q) = 16d_1N_c F (\alpha g^2) F_2(K, Q),$$

The derivative couplings with form factors $G'_{ps}^v(K, Q)$ and $G'_{ps}^s(K, Q)$ have simply a different normalization with respect to the ones from the W pion field definition: $G_{ps}^{W}(K, Q)$ and $G'_{ps}^{W}(K, Q)$. For example, it can be seen that $G_{ps}^{W}(K, Q) = \frac{32}{5}G_{ps}^{v}(K, Q)$. At this level, it is interesting to note that $G_{ps}^{v}(K, Q) = G_{2j_2s}(K, Q)$ in reasonable agreement with other results [13], and also $G'_{A}(K, Q) = G'_{V}(K, Q)$ for both pion field definitions.

The loop momentum integrals of each of the form factors above will be written and investigated for constituent quark with $K = 0$, except for the effective mass $M_3(Q)$. After a Wick rotation for the Euclidean momentum space these functions are given by:

$$F_1(0, Q) = \int_k (k - M^* - M^*^2)\bar{S}_0(k)\bar{S}_0(k + Q)\hat{R}(-k),$$

$$F_2(0, Q) = \int_k M^*\bar{S}_0(k)\bar{S}_0(k + Q)\hat{R}(-k)$$

$$M_3(Q) = 16d_1N_cM^*(\alpha g^2)\int_k \bar{S}_0(k + Q)\hat{R}(-k),$$

where $\int_k = \int \frac{dk}{(2\pi)^3}$ and the following functions in momentum space for components of the quark and gluon propagator used:

$$\bar{S}_0(k) = \frac{1}{k^2 + M^*^2},$$

$$\hat{R}(k) = 2R(k) = 6R_T(k) + 2R_L(k).$$

The only form factor that might have an ultraviolet divergence is $M_3(Q)$ if the gluon propagator does not possess particular UV behavior. The other are completely finite if the non perturbative gluon propagator is infrared regular.

The momentum structure of the form factor $F_1(0, Q)$ has a positive first derivative with respect $Q^2$ for very small $Q$, and therefore it yields negative quadratic radii. To overcome that, $F_1(0, Q)$ might be truncated by approximating the quark kernel by $\bar{S}_0(k) \approx M^*\bar{S}_0(k)$. It yields for the function $F_1(0, Q)$ the following expression:

$$F_1^T(0, Q) = M^*^2\int_k \bar{S}_0(k)\bar{S}_0(k + Q)\hat{R}(-k).$$

This truncation might be expected to correspond to making an effective mass $M^*$ to be momentum dependent in the expression of $F_1(K, Q)$.

In Figure 1, the diagrams corresponding to the expressions (15) for the Weinberg pion field definition are presented, where the pion-quark vertices with a square are the derivative ones and diagram (1d) stands for the effective mass $M_3(\bar{Q})$. The dressed (non perturbative) gluon propagator is indicated by a wavy line with a full circle and pion is represented by dashed lines. In diagrams (1a-c) the incoming constituent has momentum $K$ and the outgoing constituent quark has momentum $K + Q$, being $Q$ the total momentum transferred by pion(s). Figure 2 exhibits the diagrams for the pion constituent quark couplings for the usual pion field definition given in expression (19) with the same conventions of Figure 1.
Figure 1: These diagrams correspond to the quark-pion effective couplings from expression (15). The wavy line with a full dot is a (dressed) non-perturbative gluon propagator, the solid lines stand for a constituent quark (external line) or sea quark (internal line), and dashed lines represent pion field, the full square in a vertex represents a derivative coupling. Diagram (1d) represents the effective quark mass correction.

Figure 2: In these diagrams, the wavy line These diagrams correspond to the quark-pion effective couplings from expression (19). The wavy line with a full dot is a (dressed) non-perturbative gluon propagator, the solid lines stand for a constituent quark (external line) or sea quark (internal line), and dashed lines represent pion field, the full square in a vertex represents a derivative coupling.

4 Numerical results

To provide numerical results, two gluon propagators were chosen. A transversal one from Tandy-Maris $D_I(k)$ [32] and the other is an effective longitudinal confining one by Cornwall $D_{II}(k)$ [31]. Both of them yield DChSB and they are written below with the following association:

$$g^2 \tilde{R}^{\mu\nu}(k) \equiv h_a D_a^{\mu\nu}(k)$$

(27)

where $D_a^{\mu\nu}(k) (a = I, II)$ is one of the chosen gluon propagators from the quoted articles, $h_a$ is a real positive constant factor used in previous works [26, 29] to fix the quark gluon (running) coupling constant such as to reproduce one expected value either of the vector/axial pion coupling constant in the vacuum or vector meson coupling to constituent quarks constant, $g_V h_a = 1$, $g_A h_a = 1$ or $g_\rho h_a \approx 12$. In the present work this factor was chosen for each of the gluon propagators and pion field definition to provide $g_A(0) h_a = 1$. Their values will be shown in the caption of the corresponding figure.
The expressions for the two gluon propagators are the following:

\[
D_I(k) = \frac{8\pi^2}{\omega^4} \left[ \frac{8\pi^2 \gamma_m E(k^2)}{\ln \left( \tau + \left( 1 + k^2/\Lambda_{QCD}^2 \right)^2 \right)} \right], \quad (28)
\]

\[
D_{II}(k) = \frac{K_F}{(k^2 + M_k^2)^2}, \quad (29)
\]

where for the first expression \( \gamma_m = \frac{12}{33 - 2N_f} \), \( N_f = 4 \), \( \Lambda_{QCD} = 0.234\text{GeV} \), \( \tau = e^2 - 1 \), \( E(k^2) = \left[ 1 - \exp(-k^2/[4m_t^2]) \right]/k^2 \), \( m_t = 0.5\text{GeV} \), \( \omega = 0.5\text{GeV} \), \( D = 0.55^3/\omega \text{ (GeV)}^2 \); and for the second expression \( K_F = (2\pi M_k/(3k_e))^2 \) where \( k_e = 0.15 \) and \( M_k = 220\text{MeV} \).

In Figure (3) the resulting constituent quark (running) effective mass \( M^*_j(Q) \) is shown as a function of the constituent quark momentum for an UV cutoff \( \Lambda = 2\text{GeV} \), in dashed and continuous lines and it is compared to a result from Schwinger Dyson equations at the rainbow ladder approximation from Ref. [44]. The multiplicative factors \( 1/4 \) and \( 3/4 \) were chosen to fit the curves into a suitable scale and they are needed because of the large value of \( \Lambda \).

![Figure 3: The dynamical running constituent quark effective mass \( M^*_j(Q) \) divided by 4, \( M^*_j(Q)/4 \), for the gluon propagator \( I \), in continuous and dashed thin lines and multiplied by \( 3/4 \), \( 3/4 \times M^*_j(Q) \), in thick lines for the gluon propagator \( II \), in dashed (\( M^* = 350\text{MeV} \)) and continuous (\( M^* = 310\text{MeV} \)) lines. A gap effective mass \( M^*(Q) \) from SDE from Ref. (44) multiplied by a factor 1.15 to allow for a better comparison of the momentum dependence.](image)

In Figure (4) the axial form factor contribution for zero quark momentum \( G^W_A(0, Q) \) and its truncated version \( G^{W,tr}_A(0, Q) \) for the Weinberg pion field are presented for different values of the quark effective mass from the gap equation \( M^* \) and for the gluon propagator \( D_{II}(k) \). In all cases of the figures with the axial form factor, the linear dependence on the pion momentum from the coupling was not included. In Figure (4) the same results are exhibited for the gluon propagator \( D_I(k) \). Figures (4) and (5) present the same behavior without meaningful differences except for the relative normalization of the non truncated form factor. Besides that, a dipolar fitting for experimental results of axial pion-nucleon coupling is drawn with symbols + with a normalization to allow for comparison of the momentum dependence. It is given by [16, 20, 18]:

\[
G^\text{par}_A(Q^2) = \frac{G_0}{\left( 1 + \frac{Q^2}{M_A^2} \right)^2}, \quad (30)
\]
by considering $M_A = 1.1$ GeV and by adopting a normalization for $G_{A0}^{par}(Q^2 = 0)$ obtained in the present work for each of the gluon propagators, for the case of $M^* = 0.31$ GeV. The fitting for experimental values decreases slower than the (constituent quark) form factors $G_{W}^{A}(0, Q)$ and two reasons might directly identified for that. It might signal there is missing strength from more complete quark and gluon kernels. However it also might indicate the need to account other effects rather related to nucleon structure degrees of freedom. These two possibilities are not excludent, however they correspond to different types of constituent quark models for hadrons (baryons) since they would correspond to different roles of constituent quark interactions for the baryon structure. In any case, apart from a possible difference on the overall normalization, the difference is not very large and it appears in intermediary momenta. It can be noted that the non truncated expressions provide a positive momentum slope at $Q = 0$, these expressions therefore would provide a negative averaged quadratic axial radii. The truncated expressions correct this behavior.

In Figure (6) the axial form factor correction for the second pion field definition, $G_{A}^{U}(0, Q)$, as a function of pion momentum is shown for gluon propagators $D_{II}(k)$ and $D_{I}(k)$ for different values of the quark effective mass $M^*$. The same fitting $G_{A}^{par}(Q)$ is plotted (+) with the value at $Q = 0$ adjusted from the $G_{A}^{U}(0, Q = 0)$ to make an appropriated comparison. The truncated version of $G_{A}^{W,tr}(0, Q)$ from figures (4) and (5) have a similar behavior to $G_{A}^{U}(0, Q)$, and in fact they both are written in terms of $F_{2}(0, Q)$ with different normalizations Although the overall behavior is similar to the experimental fit, for both $G_{A}^{W,tr}(0, Q)$ and $G_{A}^{U}(0, Q)$, the form factor contribution $G_{A}^{U}(0, Q)$ has a behavior slightly closer to the experimental fit.

The axial coupling constant at the constituent quark level has been argued to be close to $g_A \simeq 3/4$ [12] or $g_A \simeq 1$ [21]. Results from the form factors are very well of the correct order of magnitude and value. Also, in the present work, it was shown in expressions (16) and (21) the axial and vector form factors are equal to each other, due to chiral symmetry, for each the two pion field definitions considered.

4.1 Pseudoscalar coupling

In figures (7) and (8) the pseudoscalar form factor $G_{ps}^{U}(0, Q)$ and its truncated version $G_{ps}^{U,tr}(0, Q)$ are presented for the gluon propagators $D_{II}(k)$ and $D_{I}(k)$ respectively. The zero momentum $Q = 0$ values are basically one order of magnitude larger than the zero momentum axial form factor as expected from phenomenology. Results

Figure 4: The normalized axial form factor $G_{A}^{W}(0, Q)$ for the Weinberg pion field as a function of the pion momentum is presented in this figure for the gluon propagator $D_{II}(k)$, untruncated expression with $b_a = 1/1.02$ and truncated one with $b_a = 1/0.75$. For different values of the sea quark effective mass $M^*$ from the gap equation. Solid thin and thick lines for $M^* = 350$ MeV; dashed lines for $310$ MeV. Signs + for the normalized fitting of expression (30), $G_{A}^{par}(Q^2)$.
The axial form factor $G_W(0, Q)$ for the Weinberg pion field as a function of the pion momentum is presented in this figure for the gluon propagator $D_I(k)$ from reference [32], being that for the untruncated expression it is taken $h_a = \frac{1}{10.83}$ and for the truncated one $h_a = \frac{1}{11.4}$, and for different values of the sea quark effective mass $M^*$ from the gap equation. Solid thin and thick lines for $M^* = 350$ MeV; dashed lines for $310$ MeV. Signs + for the fitting of expression (30), $G_{\text{ps}}(0, Q^2)$. The dipolar fitting for data from lattice QCD calculations (30) [45] is also shown with a suitable normalization at $G_{\text{ps}}(0, 0)$ to compare with the results from expressions above for the case $M^* = 0.31$ GeV. All the results from the truncated expressions for $G_{\text{ps}}(0, Q)$ yield similar results for $M^* = 0.31$ and $0.35$ GeV. Whereas the truncated version presents a monotonic decrease with momentum $Q$ the complete expression has an increase up to around $Q \sim 0.40 - 0.45$GeV and then it decreases for larger $Q$. It has therefore the same behavior of the form factor $G_W(0, Q)$ shown in the previous section. The deviation of the form factor $G_{\text{ps}}(0, Q)$ momentum dependence from the fitting $G_{\text{ps}}^{\text{par}}(0, Q)$ is slightly larger than the deviation of the axial $G_{W}(0, Q)$ form factor with respect to the corresponding nucleon-pion experimental fitting. The reasons must be the same, the momentum dependence of the quark and gluon kernels and/or internal nucleon effects.

Standard hadron effective coupling constants are usually obtained for particular values of the transferred momentum such as $Q^2 = 0$ or $Q^2 \simeq -m_\pi^2$. The only numerical values for the form factors at the timelike momenta $Q^2 < 0$ shown in this work are these next ones for the usual pseudoscalar pion coupling at $Q^2 = -m_\pi^2$, i.e. closer to the physical definition of $G_{\pi N}$ that is taken from timelike momenta at the muon or pion mass. For the quark effective mass $M^* = 0.31$GeV and the two gluon propagators two values were obtained: for the complete expression (20) and for the momentum truncated expression $G_{\text{ps}}^{\text{tr}}(0, Q)$ with (26). By considering the same factors $h_a$ adopted for the figures of the pseudoscalar form factors ($h_I = 1/0.83$ and $h_{II} = 1/0.27$), they are given by:

$$
I \quad G_{\text{ps}}^{U}(0, Q^2 = -m_\pi^2) = 1.9, \quad G_{\text{ps}}^{U}(0, 0) = 3.4, \\
I \quad G_{\text{ps}}^{U, tr}(0, Q^2 = -m_\pi^2) = 16.4, \quad G_{\text{ps}}^{U, tr}(0, 0) = 13.4, \\
II \quad G_{\text{ps}}^{U}(0, Q^2 = -m_\pi^2) = 4.1, \quad G_{\text{ps}}^{U}(0, 0) = 5.9, \\
II \quad G_{\text{ps}}^{U, tr}(0, Q^2 = -m_\pi^2) = 15.2, \quad G_{\text{ps}}^{tr}(0, 0) = 13.3.
$$

The difference between the form factor $G_{\text{ps}}^{U}(0, Q)$ and its truncated version, $G_{\text{ps}}^{U, tr}(0, Q)$, is of course present in these timelike values. The values from the truncated expression are also closer to experimental data for the nucleon-pion coupling constant and results from other calculations.
The axial (equal to the vector) form factor $G^u_A(0, Q)$ (usual pion field) as a function of the pion momentum is presented in this figure for the gluon propagators $D_I(k)$, with factor $h_a = 1.083$, and $D_{II}(k)$, with $h_a = 1.027$, and for different values of the sea quark effective mass $M^*$, from the gap equation. Solid line is used for $M^* = 350\text{MeV}$, dashed line for $M^* = 310\text{MeV}$. Sign + for the fitting of expression (30), $G^p_{\pi^+}(Q^2)$.

### 4.2 Goldberger Treiman and other relations in spacelike momenta

Next ratios of the form factors are calculated. The following momentum dependent ratios between dimensionless quantities were considered:

$$GT_W(Q) \equiv \frac{G^U_V(0, Q)}{G^U_{\beta\beta fb}(0, Q)} = \frac{F}{16m} \simeq 1,$$

$$GT(Q) = \frac{M^*}{F} \left( \frac{G^U_V(0, Q)}{G^U_{ps}(0, Q)} \right) = \frac{M^*}{F} \frac{G_V(0, Q)}{G_{2js}(0, Q)} = \frac{M^*}{F} \frac{F_2(0, Q)}{F_1(0, Q)},$$

$$\frac{G^U_A(0, Q)}{G^U_V(0, Q)} = \frac{G^U_{ps}(0, Q)}{G^U_{2js}(0, Q)} = 1,$$

where the first one $GT_W(Q)$ is an equivalent of the GTR expression for the Weinberg pion field in which the pseudoscalar pion coupling does not appear but the (symmetry breaking) scalar two pion coupling to constituent quark appears. This ratio is momentum independent and it depends on the current quark mass $m \sim 5.75\text{MeV}$ for which $16m \simeq f_\pi = F = 92\text{MeV}$ and therefore $GT_W \simeq 1$. The function $GT(Q)$ for the second pion definition has a constant factor $F/M^*$ such that if the GTR relation is satisfied the ratio $GT(Q) \to 1$ and this is verified for very large $M^*$. The last expression has two chiral symmetry relations for form factors, and their corresponding effective coupling constants for the second pion field definition.

In figure (9) the ratio $GT(Q)$ is presented as a function of momentum for different effective quark masses $M^*$. The ratio $GT(Q)$ does not satisfy necessarily the GTR at $Q = 0$ because the quark effective masses are not large enough. This ratio $GT(Q)$ has the same behavior found in other works [15]. The deviation from the GTR intrinsically due to the momentum dependence of each of the form factors for the nucleon level Goldberger-Treiman relation is usually denoted by $R(Q)$. It is usually parameterized in terms of the nucleon mass $M$ [15], and by substituting $M$ by the quark effective mass $M^*$ it is given by the following expression:

$$G_A(Q^2) = \frac{f_\pi}{M^*} G_{\pi NN}(Q^2) - \frac{Q^2}{4M^*} R(Q^2),$$
Figure 7: The pseudoscalar form factor \( G_{ps}(0, Q) \) as a function of the quark momentum is presented in this figure for the gluon propagator \( D_{II}(k) \), with factor \( h_a = 0.27 \), and for different values of the sea quark effective mass \( M^* \), from the gap equation. Results from both the complete and the truncated (tr) expressions are shown. Solid lines are used for \( M^* = 350 \) MeV, dashed lines for \( M^* = 310 \) MeV. Signs + for the corresponding fitting of expression (30), \( G_{par}^{\text{par}}(Q^2) \).

where \( G_{\pi N}(Q^2) \) is to be substituted by \( G_{ps}(Q) \). By considering the constituent quark mass \( M^* = 0.28 \) GeV and 0.31 GeV this function is exhibited in figure (10) for the second pion definition. It goes to zero quite fast with increasing \( Q \) depending not only on the quark effective mass \( M^* \) but also on the gluon propagator considered.

### 4.3 Averaged quadratic radii

Next, the corresponding strong averaged quadratic radii are defined from the different pion-constituent quark couplings presented above. Since the form factors are dimensionless the corresponding axial and pseudoscalar quadratic radii were defined by:

\[
< r^2 >_A^W = -6 \frac{dG_A^W(0, Q)}{dQ^2} \bigg|_{Q=0} = < r^2 >_V^W, \tag{39}
\]

\[
< r^2 >_{A,\text{tr}}^W = -6 \frac{dG^W_{A,\text{tr}}(0, Q)}{dQ^2} \bigg|_{Q=0} = < r^2 >_{V,\text{tr}}^W, \tag{40}
\]

\[
< r^2 >_A^U = -6 \frac{dG_A^U(0, Q)}{dQ^2} \bigg|_{Q=0} = < r^2 >_V^U, \tag{41}
\]

\[
< r^2 >_{ps} = -6 \frac{dG_{ps}(0, Q)}{dQ^2} \bigg|_{Q=0} = < r^2 >_{2js}^2, \tag{42}
\]

\[
< r^2 >_{ps,\text{tr}} = -6 \frac{dG_{ps,\text{tr}}(0, Q)}{dQ^2} \bigg|_{Q=0} = < r^2 >_{2js}^{\text{tr}}, \tag{43}
\]

where in the right hand side of these expressions the relations to vector and scalar quadratic radii from the form factors defined in the previous sections are exhibited. In [28] the light vector/axial mesons couplings to constituent quarks were considered to provide corresponding quadratic radii. The corresponding averaged axial and vector quadratic radii seen by the coupling to the pion, presented in this work, also turn out to be equal. Both results, from the pion
The pseudoscalar form factor $G_{\mu \nu}(0, Q)$ as a function of the quark momentum is presented in this figure for the gluon propagator $D_I(k)$, with factor $h_a = \frac{1}{10}$, and for different values of the sea quark effective mass $M^\ast$, from the gap equation. Results from both the complete and the truncated (tr) expressions are shown. Solid lines are used for $M^\ast = 350 \text{ MeV}$, dashed lines for $M^\ast = 310 \text{ MeV}$. Signs $+$ for the corresponding fitting of expression (30), $G_{\mu \nu}^{\text{par}}(Q^2)$, and axial mesons couplings, are to be added, i.e. in fact expressions (39-41) provide corrections to the corresponding quadratic radii. However their experimental values, at the nucleon level, must receive further corrections since vector and axial a.q.r. are different from each other and expected to follow: $\sqrt{\langle r^2_V \rangle / \langle r^2_A \rangle} \simeq 1.6$ [12].

In Figure (11) the different estimations for the axial quadratic radius contribution for the two pion definitions, $W$ and $U$, and for the two gluon propagators, as functions of the quark effective mass $M^\ast$. In the figures with a.q.r. the factors $h_a$ were considered $h_I = 3$ and $h_{II} = 1$, such that results could be compared with results from [28]. In the case of the Weinberg definition there are also results for the truncated expression. The axial radius (contribution) $\langle r^2 \rangle^W_A$ is negative because of the behavior of the axial form factor close to zero exchanged momentum and this unexpected behavior is corrected by the truncated expression as discussed above. Besides the problem with the sign for $\langle r^2 \rangle^W_A$ it is also noted a different behavior in the $M^\ast$-dependence of the axial quadratic radii between $\langle r^2 \rangle^W_A$ and $\langle r^2 \rangle^A_{\text{tr}}$, being that the former presents a stronger variation for increasing $M^\ast$ and the latter a smoother variation.

These axial quadratic radii correction due to the pion are smaller than the vector/axial quadratic radii due to the vector/axial light mesons calculated with the same method for both gluon propagators in [28]. In that work the axial quadratic radii found from the coupling to the $A_1$ meson, $\langle r^2_{a.m.} \rangle_A$, were estimated to be in the following range of values - for the same range of values of the quark effective mass $M^\ast$ - by keeping the corresponding $h_a$ to the ones used in the figures for the a.q.r.: $\langle r^2_{a.m.} \rangle_A \sim 0.4 - 0.2 \text{ fm}^2$, $D_{II}(k)$, $\langle r^2_{a.m.} \rangle_A \sim 4.0 - 2.0 \text{ fm}^2$, $D_I(k)$, (44) respectively for gluon propagators $D_{II}(k)$ and $D_I(k)$. Of course the estimations for $\langle r^2_{a.m.} \rangle_A$ with $D_I(k)$ are extremely large, also present in figures [11][12] and this had been attributed rather to the corresponding quark-gluon coupling constant and gluon propagator strengths. Both resulting values however are basically of the order of magnitude as (or larger than) the estimation for constituent quark radius $\sqrt{\langle r^2 \rangle_{CQ}} \simeq 0.2 - 0.3 \text{ fm}$ [12][23], apart from normalizations of the quark-gluon coupling constant. The experimental value for the axial radius of the nucleon is $\langle r^2_A \rangle^{1/2} \simeq 0.68 \text{ fm}$ [11][13] and there are many estimations from lattice $\langle r^2_A \rangle^{1/2} \simeq 0.45 - 0.50 \text{ fm}$, for example in [40][18] and references therein.
Similar behavior was found for the pseudoscalar quadratic radii presented in the next figure \[12\] from expressions \[12, 13\], complete and truncated ones, as functions of the quark effective mass \(M^*\) for the two gluon propagators. The non truncated expression provides negative values and they are presented with a sign minus. One of them is divided by factor 10 for \(D_I(k)\) to fit into a reasonable scale of the figure. To make possible a correct calculation with the previous figure it was assumed \(h_I = 3\) and \(h_{II} = 1\). The axial \(< r^2 >_A\) contribution was found to be smaller than the pseudoscalar \(< r^2 >_{ps}\) in all cases. This is related to the fact that the pseudoscalar form factor normalization is larger than the axial form factor one. At this level all the form factors reduce to only \(F_1(K,Q)\) and \(F_2(K,Q)\) and the truncated version \(F^{1tr}_I(K,Q)\). However the difficulty in fixing the quark-gluon vertex and the overall momentum behavior of the quark and gluon propagators cannot be neglected. When compared to the value \(\sqrt{< r^2 >_{CQ}} \approx 0.2 - 0.3\)fm from \[13, 21\] the gluon propagator \(D_I(k)\) provides larger values for \(< r^2 >\) and the gluon propagator \(D_{II}(k)\) again provides smaller values. The reasons for the differences between \(< r^2 >_{ps}\) and the truncated-\(< r^2 >_{ps}\) must be the same as the ones responsible for the discrepancies in the axial radii from figure \[11\]. Besides that, it might be interesting, for the sake of comparison, to compare with the scalar radius of the lightest hadron, the pion, that has been calculated, for example, in lattice with \(< r^2 > = 0.6\)fm\(^2\) \[13\]. The pion charge radius has estimations for example in lattice \(< r^2 > = 0.37\)fm\(^2\) \[8\] and with SDE \(< r^2 > = 0.46 - 0.48\)fm\(^2\) \[18\], whereas its experimental value \(< r^2 > \approx 0.45\)fm\(^2\) \[20, 24\]. The pion scalar radius seems therefore to be larger than its charge radius analogously to the fact that according to the present results the pseudoscalar, and also scalar, radii are larger than the axial and vector radii.

5 Summary and discussion

Pion- constituent quark momentum dependent form factors were investigated from one loop background field method for the one non perturbative gluon exchange quark interaction from the QCD effective action. At this level, the pseudoscalar coupling only shows up for the usual pion field definition in terms of unitary functions \(U, U^\dagger\) but not for the Weinberg pion field. Besides the usual pseudoscalar pion coupling, other derivative pion -scalar and pseudoscalar currents form factors were also found in the leading order of the determinant expansion in expressions \[18, 19\] and also \[19, 22\]. Several of them have a reduced strength with respect to the usual scalar and pseudoscalar form factors by a constant coefficient of the order of \(1/M^*\). By means of an integration by parts these terms might contribute for the vector and axial channels. All the (eleven) resulting form factors, pseudoscalar, scalar, vector
and axial, were found to be written in terms of only two momentum dependent functions \( F_1(0,Q) \) and \( F_2(0,Q) \) for zero external constituent quark momentum, with different coefficients. A truncated momentum dependence of the quark kernel for \( F_1(0,Q) \) was also considered such that the resulting form factors, \( G_{WA}^{WTR}(0,Q) \) and \( G_{U}^{U}(0,Q) \), were shown to have a decreasing monotonic behavior more similar to the experimental results, corresponding rather to the function \( F_2(0,Q) \). The truncated expressions might in fact correspond to considering running momentum dependent effective sea quark mass from the gap equation. Besides that, these truncated expressions yield positive quadratic averaged radii. Different values for the sea quark effective mass \( M^* \) were considered and it mostly contributes for the overall normalization of the form factors. The first momentum dependent function presented was the constituent quark effective mass correction \( M_3(Q) \). Its momentum dependence is in excellent agreement with estimations from SDE calculations, except for its overall normalization that appeared to be very large due to absence of an UV cutoff. It is important to stress that the mechanisms that give rise to the gap effective mass \( M^* \) and to the mass \( M_3(Q) \) are different. However the behavior of constituent quark mass \( M_3(Q) \) is nearly independent of the scalar condensate contribution for the (constant) quark effective mass \( M^* \). At the level of the calculation presented, the axial and vector form factors are equal to each other for each of the pion field definitions. The same chiral relation appeared for the scalar and pseudoscalar form factors for the second pion definition. The axial and pseudoscalar form factors were compared to fittings of available experimental data for pion nucleon form factors by adjusting the values at zero momenta. Results showed that the momentum dependence of constituent quark coupling to pions is not very different from the nucleon coupling to pions. The larger difference between experimental (nucleon form factor) values and the present form factors appear in the range of \( 0.15 < Q < 1.4 \)GeV for \( M^* = 0.31 \)GeV. This might signal the need for improved momentum structure of the quark and gluon kernels but it might also signal need to account for effects from nucleon structure. The pseudoscalar form factor has a larger strength than the axial one, in agreement with expectations from phenomenology. This conclusion remains valid if other components for the axial form factor are included such as the coupling to light axial mesons, as seen by comparing with results from Ref. [28] in which vector/axial mesons couplings to constituent quark had been investigated by means of the same method employed in the present work. A systematic and more general analysis will be presented elsewhere.

The pseudoscalar form factor at the timelike point \( Q^2 = -m_\pi^2 \), closer to current physical definitions of \( g_{\pi N} \), was obtained for the complete (or truncated) expressions being smaller (or larger) than the zero momentum \( Q^2 = 0 \) case. Different momentum dependent and independent ratios between the form factors were also presented. Some of them simply show the resulting chiral symmetry relations, eg. between vector and axial ones, or between scalar
The axial quadratic averaged radius (contribution) for the two pion definitions, \( W \) and \( U \), and two gluon propagators, \( I \) and \( II \), as functions of the effective quark mass \( M^* \). The factors \( h_a \) were chosen to be \( h_I = 3 \) and \( h_{II} = 1 \). The numerical result for \( <r^2>_A^W \) has a sign minus and the results for the gluon propagator \( D_I \) it is divided by 5 to fit in the scale of the figure.

and pseudoscalar ones. The momentum dependence of the Goldberger Treiman relation (GTR) was also presented by considering the pseudoscalar and axial form factors for spacelike momenta and a qualitative agreement with calculations at the nucleon level as found. Finally the corresponding results for the pseudoscalar and contribution to the axial constituent quark averaged quadratic radii were obtained as functions of a constant quark effective mass \( M^* \) from the gap equation. In particular resulting values for the axial/vector quadratic radii are somewhat smaller than estimations of the constituent quark axial/vector radii from the coupling to light axial/vector mesons obtained with the same method [28]. The structureless pion limit might have had effect on the estimations but this structureless limit had also been considered for the vector/axial mesons. In general the pseudoscalar quadratic radius is larger than the axial radius (from both couplings to pions and axial mesons) due to the corresponding form factors normalizations. This becomes clear by noting all the quadratic radii and form factors depend on only two momentum dependent functions. The relevance of each of the constituent quark degree of freedom presented in this work and [28] for nucleon structure and corresponding form factors is to be investigated elsewhere.
