Abstract: We consider testing the significance of a subset of covariates in a nonparametric regression. These covariates can be continuous and/or discrete. We propose a new kernel-based test that smooths only over the covariates appearing under the null hypothesis, so that the curse of dimensionality is mitigated. The test statistic is asymptotically pivotal and the rate of which the test detects local alternatives depends only on the dimension of the covariates under the null hypothesis. We show the validity of wild bootstrap for the test. In small samples, our test is competitive compared to existing procedures.

MSC 2010 subject classifications: Primary 62G08, 62G10; secondary 62G20.

Keywords and phrases: Asymptotic pivotal test statistic, bootstrap, kernel smoothing, $U$-statistic.

1 Introduction ................................................................. 644
2 Testing framework and procedure ................................. 645
Testing the significance of covariates is common in applied regression analysis. Sound parametric inference hinges on the correct functional specification of the regression function, but the likelihood of misspecification in a parametric framework cannot be ignored, especially as applied researchers tend to choose functional forms on the basis of parsimony and tractability. Significance testing in a nonparametric framework has therefore obvious appeal as it requires much less restrictive assumptions. Fan (1996); Fan and Li (1996); Racine (1997); Chen and Fan (1999); Lavergne and Vuong (2000); Ait-Sahalia, Bickel and Stoker (2001), and Delgado and González Manteiga (2001) proposed tests of significance for continuous variables in nonparametric regression models. A related issue is testing for the equality of nonparametric regression functions across subsamples, see Delgado (1993); Dette and Neumeyer (2001); Lavergne (2001); Neumeyer and Dette (2003); Racine, Hart and Li (2006). When the division into subsamples is governed by a discrete random variable, this is akin to testing the significance of this discrete variable, see Lavergne (2001). Volgushev et al. (2013) considered significance testing in nonparametric quantile regression. For each test, one needs first to estimate the model without the covariates under test, that is under the null hypothesis. The result is then used to check the significance of extra covariates. Two competing approaches are then possible. In the “smoothing approach,” one regresses the residuals onto the whole set of covariates nonparametrically, while in the “empirical process approach” one uses the empirical process of residuals marked by a function of all covariates.

In this work, we adopt an hybrid approach to develop a new significance test of a subset of covariates in a nonparametric regression. Our new test has three specific features. First, it does not require smoothing with respect to the covariates under test as in the “empirical process approach.” This allows to mitigate the curse of dimensionality that appears with nonparametric smoothing, hence improving the power properties of the test. Our simulation results show that indeed our test can be more powerful than such competitors under different situations.
kind of alternatives. Second, the test statistic is asymptotically pivotal as in the “smoothing approach,” while wild bootstrap can be used to obtain small samples critical values of the test. This yields a test whose level is well controlled by bootstrapping independently of the smoothing parameter choice, as shown in our simulations. Third, our test equally applies whether the covariates under test are continuous or discrete, showing that there is no need of a specific tailored procedure for each situation. Hence our test also applies to comparing two or more nonparametric regressions that are characterized by different values of a discrete random variable.

The paper is organized as follows. In Section 2, we present our testing procedure. In Section 3, we study its asymptotic properties under a sequence of local alternatives and we establish the validity of wild bootstrap. In Section 4, we compare the small sample behavior of our test to some existing procedures. Section 6 gathers our proofs.

2. Testing framework and procedure

2.1. Testing principle

We want to assess the significance of \( X \in \mathbb{R}^q \) in the nonparametric regression of \( Y \in \mathbb{R} \) on \( W \in \mathbb{R}^p \) and \( X \). Formally, this corresponds to the null hypothesis

\[
H_0 : \mathbb{E}[Y \mid W, X] = \mathbb{E}[Y \mid W] \quad \text{a.s.}
\]

which is equivalent to

\[
H_0 : \mathbb{E}[u \mid W, X] = 0 \quad \text{a.s.}
\] (1)

where \( u = Y - \mathbb{E}[Y \mid W] \). The corresponding alternative hypothesis is

\[
H_1 : \mathbb{P}\{\mathbb{E}[u \mid W, X] = 0\} < 1.
\]

The following result is the cornerstone of our approach. It characterizes the null hypothesis \( H_0 \) using a suitable unconditional moment equation.

**Lemma 1.** Let \((W_1, X_1, u_1)\) and \((W_2, X_2, u_2)\) be two independent draws of \((W, X, u), \nu(W)\) a strictly positive function on the support of \( W \) such that \( \mathbb{E}[u^2 \nu^2(W)] < \infty \), and \( K(\cdot) \) and \( \psi(\cdot) \) even functions with (almost everywhere) positive Fourier integrable transforms. Define

\[
I(h) = \mathbb{E}\left[u_1 u_2 \nu(W_1) \nu(W_2) h^{-p} K((W_1 - W_2) / h) \psi(X_1 - X_2)\right].
\]

Then for any \( h > 0 \), \( I(h) \geq 0 \) and

\[
\mathbb{E}[u \mid W, X] = 0 \quad \text{a.s.} \iff I(h) = 0 \iff \lim_{h \to 0} I(h) = 0.
\]

**Proof.** Let \( \langle \cdot, \cdot \rangle \) denote the standard inner product. Using Fourier Inversion Theorem, change of variables, and elementary properties of conditional expectation,

\[
I(h) = \mathbb{E}\left[u_1 u_2 \nu(W_1) \nu(W_2) \int_{\mathbb{R}^p} e^{2\pi i \langle t, W_1 - W_2 \rangle} \mathcal{F}[K](th) dt\right]
\]
\[
\int_{\mathbb{R}^q} e^{2\pi i (s_1 - X_2)} F[\psi](s) \, ds \\
= \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \left| \mathbb{E}[u | W, X] \nu(W) e^{2\pi i (t, W) + \langle s, X \rangle} \right|^2 \\
\times F[K](\theta h) F[\psi](s) \, dt \, ds.
\]

Since the Fourier transforms \(F[K]\) and \(F[\psi]\) are strictly positive, \(I(h) \geq 0\). Moreover \(I(h) = 0\) iff \(E[u | W, X] \nu(W) e^{2\pi i (t, W) + \langle s, X \rangle} = 0\) \(\forall t, s\).

This is equivalent to \(E[u | W, X] \nu(W) = 0\) a.s., which by our assumption on \(\nu(\cdot)\) is equivalent to \(H_0\).

When \(h \to 0\), \(F[K](\theta h) \to F[K](0)\), so that by Lebesgue dominated convergence \(\lim_{h \to 0} I(h) \geq 0\), and \(= 0\) iff \(H_0\) holds, by the same reasoning as above.

2.2. The test

Lemma 1 holds whether the covariates \(W\) and \(X\) are continuous or discrete. For now, we assume \(W\) is continuously distributed, and we later comment on how to modify our procedure in the case where some of its components are discrete. We however do not restrict \(X\) to be continuous. Since it is sufficient to test whether \(I(h) = 0\) for any arbitrary \(h\), we can choose \(h\) to obtain desirable properties. So we consider a sequence of \(h\) decreasing to zero when the sample size increases, which is one of the ingredient that allows to obtain a tractable asymptotic distribution for the test statistic.

Assume we have at hand a random sample \((Y_i, W_i, X_i), 1 \leq i \leq n\), from \((Y, W, X)\). In what follows, \(f(\cdot)\) denotes the density of \(W\), \(r(\cdot) = \mathbb{E}[Y | W = \cdot]\), \(u = Y - r(W)\), and \(f_i, r_i, u_i\) respectively denote \(f(W_i), r(W_i), Y_i - r(W_i)\). Since nonparametric estimation should be entertained to approximate \(u_i\), we consider usual kernel estimators based on kernel \(L(\cdot)\) and bandwidth \(g\). With \(L_{nik} = \frac{1}{g} L(W_i - W_k)\), let

\[
\hat{f}_i = (n - 1)^{-1} \sum_{k \neq i, k=1}^{n} L_{nik}, \\
\hat{r}_i = \frac{1}{\hat{f}_i} \left(\frac{1}{n - 1} \sum_{k \neq i, k=1}^{n} Y_k L_{nik}\right),
\]

so that \(\hat{u}_i = Y_i - \hat{r}_i = \frac{1}{\hat{f}_i} \left(\frac{1}{n - 1} \sum_{k \neq i, k=1}^{n} (Y_i - Y_k) L_{nik}\right)\).

Denote by \(n^{(m)}\) the number of arrangements of \(m\) distinct elements among \(n\), and by \([^1/n^{(m)}] \sum_a\), the average over these arrangements. In order to avoid random denominators, we choose \(\nu(W) = f(W)\), which fulfills the assumption.
of Lemma 1. Then we can estimate \( I(h) \) by the U-statistic
\[
\hat{I}_n = \frac{1}{n^{(2)}} \sum_a \hat{u}_i \hat{j}_i \hat{u}_j \hat{j}_j K_{nij} \psi_{ij}
\]
\[
= \frac{1}{n^{(2)}} (n-1)^2 \sum_a \sum_{k \neq i} \sum_{l \neq j} (Y_i - Y_k) (Y_j - Y_l) L_{nik} L_{njl} K_{nij} \psi_{ij},
\]
with \( K_{nij} = \frac{1}{h^p} K\left(\frac{W_i - W_j}{h}\right) \) and \( \psi_{ij} = \psi(X_i - X_j) \). We also consider the alternative statistic
\[
\hat{I}_n = \frac{1}{n^{(4)}} \sum_a (Y_i - Y_k) (Y_j - Y_l) L_{nik} L_{njl} K_{nij} \psi_{ij}.
\]

It is clear that \( \hat{I}_n \) is obtained from \( \hat{I}_n \) by removing asymptotically negligible “diagonal” terms. Under the null hypothesis, both statistics will have the same asymptotic normal distribution, but removing diagonal terms reduces the bias of the statistic under \( H_0 \). Our statistics \( \hat{I}_n \) and \( \hat{I}_n \) are respectively similar to the ones of Fan and Li (1996) and Lavergne and Vuong (2000), with the fundamental difference that there is no smoothing relative to the covariates \( X \). Indeed these authors used a multidimensional smoothing kernel over \((W, X)\), that is \( h^{-p-q} K((W_i - W_j)/h, (X_i - X_j)/h) \), while we use \( K_{nij} \psi_{ij} \). For \( I_n \) being either \( \hat{I}_n \) or \( \hat{I}_n \), we will show that \( nh^{p/2} I_n \) converges to \( N(0, \omega^2) \) in distribution under \( H_0 \) and \( nh^{p/2} I_n \overset{p}{\rightarrow} \infty \) under \( H_1 \). By contrast, the statistics of Fan and Li (1996) and Lavergne and Vuong (2000) exhibit a \( nh^{(p+q)/2} \) rate of convergence. The alternative test of Delgado and González Manteiga (2001) uses the kernel residuals \( \hat{u}_i \) and the empirical process approach of Stute (1997). This avoids extra smoothing, but at the cost of a test statistic with a non pivotal asymptotic law under \( H_0 \). Hence, our proposal is an hybrid approach that combines the advantages of existing procedures, namely smoothing only for the variables \( W \) appearing under the null hypothesis but with an asymptotic normal distribution for the statistic. Given a consistent estimator \( \omega^2_n \) of \( \omega^2 \), as provided in the next section, we obtain an asymptotic \( \alpha \)-level test of \( H_0 \) as

\[
\text{Reject } H_0 \text{ if } \frac{nh^{p/2} I_n}{\omega_n} > z_{1-\alpha},
\]

where \( z_{1-\alpha} \) is the \((1 - \alpha)\)-th quantile of the standard normal distribution. In small samples, we will show the validity of a wild bootstrap scheme to obtain critical values.

The test applies whether \( X \) is continuous or has some discrete components. When \( X \) is discrete, the null hypothesis under test is that the regression functions \( \mathbb{E}[Y \mid W, X] \) are equal across possible values of \( X \). The procedure is also easily adapted to some discrete components of \( W \). In that case, one would replace kernel smoothing by cells’ indicators for the discrete components, so that for \( W \) composed of continuous \( W_c \) of dimension \( p_c \) and discrete \( W_d \), one would use \( h^{-p_c} K\left(\frac{W_{c} - W_{c}'}{h}\right) \mathbb{I}(W_{id} = W_{jd}) \) instead of \( K_{nij} \). It would also be possible to smooth on the discrete components, as proposed by Racine and Li (2004). To obtain scale invariance, we recommend that observations on covariates should be scaled, say by their sample standard deviation as is customary in nonpara-
metric estimation. It is equally important to scale the $X_i$ before they are used as arguments of $\psi(\cdot)$ to preserve such invariance.

The outcome of the test may depend on the choice of the kernels $K(\cdot)$ and $L(\cdot)$, while this influence is expected to be limited as usual in nonparametric estimation. The choice of the function $\psi(\cdot)$ might be more important, but our simulations reveal that it is not so. From our theoretical study, this function, as well as $K(\cdot)$ should possess an almost everywhere positive and integrable Fourier transform. This is true for (products of) the triangular, normal, Laplace, and logistic densities, see Johnson, Kotz and Balakrishnan (1995), and for a Student density, see Hurst (1995). Alternatively, one can choose $\psi(x)$ as a univariate density applied to some transformation of $x$, such as its norm. This yields $\psi(x) = g(\|x\|)$ where $g(\cdot)$ is any of the above univariate densities. This is the form we will consider in our simulations to study the influence of $\psi(\cdot)$.

3. Theoretical properties

We here give the asymptotic properties of our test statistics under $H_0$ and some local alternatives. To do so in a compact way, we consider the sequence of hypotheses

$$H_{1n} : \mathbb{E}[Y | W, X] = r(W) + \delta_n d(W, X), \quad n \geq 1,$$

where $d(\cdot)$ is a fixed integrable function. Since $r(W) = \mathbb{E}[Y | W]$, our setup imposes $\mathbb{E}[d(W, X) | W] = 0$. The null hypothesis corresponds to the case $\delta_n \equiv 0$, while considering a sequence $\delta_n \to 0$ yields local Pitman-like alternatives.

3.1. Assumptions

We begin by some useful definitions.

**Definition 1.** (i) $U^p$ is the class of integrable uniformly continuous functions from $\mathbb{R}^p$ to $\mathbb{R}$;

(ii) $D^p_\alpha$ is the class of $m$-times differentiable functions from $\mathbb{R}^p$ to $\mathbb{R}$, with derivatives of order $[s]$ that are uniformly Lipschitz continuous of order $s - [s]$, where $[s]$ denotes the integer such that $[s] \leq s < [s] + 1$.

Note that a function belonging to $U^p$ is necessarily bounded.

**Definition 2.** $K^p_m$, $m \geq 2$, is the class of even integrable functions $K : \mathbb{R}^p \to \mathbb{R}$ with compact support satisfying $\int K(t)dt = 1$ and, if $t = (t_1, \ldots, t_p)$,

$$\int_{\mathbb{R}^p} t_1^{\alpha_1} \cdots t_p^{\alpha_p} K(t) dt = 0 \text{ for } 0 < \sum_{i=1}^p \alpha_i \leq m - 1, \alpha_i \in \mathbb{N} \quad \forall i$$

This definition of higher-order kernels is standard in nonparametric estimation. The compact support assumption is made for simplicity and could be relaxed at the expense of technical conditions on the rate of decrease of the kernels at infinity, see e.g. Definition 1 in Fan and Li (1996). In particular, the gaussian kernel could be allowed for. We are now ready to list our assumptions.
Assumption 1. (i) For any $x \in \mathbb{R}^q$ in the support of $X$, the vector $W$ admits a conditional density given $X = x$ with respect to the Lebesgue measure in $\mathbb{R}^p$, denoted by $\pi(\cdot \mid x)$. Moreover, $\mathbb{E}[Y^8] < \infty$. (ii) The observations $(W_i, X_i, Y_i), i = 1, \ldots, n$ are independent and identically distributed as $(W, X, Y)$.

The existence of the conditional density given $X = x$ for all $x \in \mathbb{R}^q$ in the support of $X$ implies that $W$ admits a density with respect to the Lebesgue measure on $\mathbb{R}^p$. As noted above, our results easily generalizes to some discrete components of $W$, but for the sake of simplicity we do not formally consider this in our theoretical analysis.

Assumption 2. (i) $f(\cdot)$ and $r(\cdot)f(\cdot)$ belong to $\mathcal{U}^p \cap D^p_s$, $s \geq 2$;
(ii) $\mathbb{E}[u^2 \mid W = \cdot]f(\cdot)$, $\mathbb{E}[u^4 \mid W = \cdot]f^4(\cdot)$ belong to $\mathcal{U}^p$;
(iii) the function $\psi(\cdot)$ is bounded and has an almost everywhere positive and integrable Fourier transform;
(iv) $K(\cdot) \in \mathcal{K}^p_s$ and has an almost everywhere positive and integrable Fourier transform, while $L(\cdot) \in \mathcal{K}^p_s$ and is of bounded variation;
(v) let $\sigma^2(w, x) = \mathbb{E}[u^2 \mid W = w, X = x]$, then $\sigma^2(\cdot, x)f^2(\cdot)\pi(\cdot \mid x)$ belongs to $\mathcal{U}^p$ for any $x$ in the support of $X$, has integrable Fourier transform, and $\mathbb{E}[\sigma^4(W, X)f^4(W)\pi(W \mid X)] < \infty$;
(vi) $\mathbb{E}[d^2(W, X) \mid W = \cdot]f^2(\cdot)\pi(\cdot \mid x)$ is integrable and squared integrable for any $x$ in the support of $X$, and $\mathbb{E}[d^2(W, X)f^2(W)\pi(W \mid X)] < \infty$.

Standard regularity conditions are assumed for various functions. A higher-order kernel $L(\cdot)$ is used in conjunction with the differentiability conditions in (i) to ensure that the bias in nonparametric estimation is small enough.

3.2. Asymptotic analysis

The following result characterizes the behavior of our statistics under the null hypothesis and a sequence of local alternatives.

Theorem 1. Let $I_n$ be any of the statistics $\hat{I}_n$ or $\tilde{I}_n$. Under Assumptions 1 and 2, and if as $n \to \infty$ (i) $g, h \to 0$, (ii) $nq^{4p/3}/\ln n, nh^p \to \infty$, (iii) $nh^{p/2}g^{2s} \to 0$, and (iv) $h/g \to 0$ if $I_n = \hat{I}_n$ or $h/g^2 \to 0$ if $I_n = \tilde{I}_n$, then

(i) If $\delta_n^2 nh^{p/2} \to C$ with $0 \leq C < \infty$, $nh^{p/2}I_n \xrightarrow{d} \mathcal{N}(C\mu, \omega^2)$ where

$$\mu = \mathbb{E} \left[ \int d(w, X_1) d(w, X_2) f^2(w) \pi(w \mid X_1) \pi(w \mid X_2) \psi(X_1 - X_2) dw \right] > 0$$

and

$$\omega^2 = 2 \int K^2(s) \, ds$$

$$\mathbb{E} \left[ \int \sigma^2(w, X_1) \sigma^2(w, X_2) f^4(w) \pi(w \mid X_1) \pi(w \mid X_2) \psi^2(X_1 - X_2) dw \right].$$

(ii) If $\delta_n^2 nh^{p/2} \to \infty$, $nh^{p/2}I_n \xrightarrow{p} \infty$. 
The rate of convergence of the test statistic depends only on the dimension of \( W \), the covariates present under the null hypothesis, but not on the dimension of \( X \), the covariates under test. Similarly, the rate of local alternatives that are detected by the test depends only on the dimension of \( W \) and \( X \). Conditions (i) to (iv) together require that \( s > p/2 \) for \( I_n = \hat{I}_n \) and \( s > p/4 \) for \( I_n = \tilde{I}_n \), so removing diagonal terms in \( \hat{I}_n \) allows to weaken the restrictions on the bandwidths. Condition (ii) could be slightly weakened to \( ng^p \to \infty \) at the price of handling high order \( U \)-statistics in the proofs, but allows for a shorter argument based on empirical processes, see Lemma 3 in the proofs section.

To estimate \( \omega^2 \), we can either mimic Lavergne and Vuong (2000) to consider

\[
\hat{\omega}^2_n = \frac{2h_p}{n(\delta)} \sum_a (Y_i - Y_k) (Y_i - Y_k) (Y_j - Y_l) (Y_j - Y_l) L_{nik}L_{nik'}L_{njl}L_{njl'}K_{nij}^2 \psi_{ij},
\]

or generalize the variance estimator of Fan and Li (1996) as

\[
\tilde{\omega}^2_n = \frac{2h_p}{n(\delta n^{(2)})} \sum_a \hat{u}_i^2 \hat{u}_j^2 \hat{u}_k^2 \hat{u}_l^2 K_{nij}^2 \psi_{ij}^2.
\]

The first one is consistent for \( \omega^2 \) under both the null and alternative hypothesis, but the latter is faster to compute.

**Corollary 1.** Let \( I_n \) be any of the statistics \( \hat{I}_n \) or \( \tilde{I}_n \) and let \( \omega_n \) denote any of \( \hat{\omega}_n \) or \( \tilde{\omega}_n \). Under the assumptions of Theorem 1, the test that rejects \( H_0 \) when \( nh^{p/2}I_n/\omega_n > z_{1-\alpha} \) is of asymptotic level \( \alpha \) under \( H_0 \) and is consistent under the sequence of local alternatives \( H_{1n} \) provided \( \delta_n^2 nh^{p/2} \to \infty \).

### 3.3. Bootstrap critical values

It is known that asymptotic theory may be inaccurate for small and moderate samples when using smoothing methods. Hence, as in Härdle and Mammen (1993) or Delgado and González Manteiga (2001), we consider a wild bootstrap procedure to approximate the quantiles of our test statistic. Resamples are obtained from \( Y_i^* = \hat{r}_i + u_i^* \), where \( u_i^* = \eta_i \tilde{u}_i \) and \( \eta_i \) are i.i.d. variables independent of the initial sample with \( \mathbb{E}\eta_i = 0 \) and \( \mathbb{E}\eta_i^2 = \mathbb{E}\eta_i^3 = 1 \), \( 1 \leq i \leq n \). The \( \eta_i \) could for instance follow the two-point law of Mammen (1993). With at hand a bootstrap sample \( (Y_i^*, W_i, X_i) \), \( 1 \leq i \leq n \), we obtain a bootstrapped statistic \( nh^{p/2}I_n^*/\omega_n^* \) with bootstrapped observations \( Y_i^* \) in place of original observations \( Y_i \). When the scheme is repeated many times, the bootstrap critical value \( z_{1-\alpha,n}^* \) at level \( \alpha \) is the empirical \((1-\alpha)\)-th quantile of the bootstrapped test statistics. The asymptotic validity of this bootstrap procedure is guaranteed by the following result.

**Theorem 2.** Suppose Assumptions 1, 2, and Conditions (i) to (iii) of Theorem 1 hold. Moreover, assume \( \inf_{w \in S_w} f(w) > 0 \) and \( h^2 \to 0 \). Then for \( I_n^* \)
equal to any of $\hat{I}_n^*$ and $\tilde{I}_n^*$,

$$\sup_{z \in \mathbb{R}} \left| P \left[ nh^{p/2} I_n^*/\omega_n^* \leq z \mid Y_1, W_1, X_1, \ldots, Y_n, W_n, X_n \right] - \Phi(z) \right| \overset{p}{\to} 0,$$

where $\Phi(\cdot)$ is the standard normal distribution function.

4. Monte Carlo study

We investigated the small sample behavior of our test and studied its performance relative to alternative tests. We generated data through

$$Y = (W'\theta)^3 - W'\theta + \delta d(X) + \varepsilon$$

where $W$ follows a two-dimensional standard normal, $X$ independently follows a $q$-variate standard normal, $\varepsilon \sim N(0, 4)$, and we set $\theta = (1, -1)'/\sqrt{2}$. The null hypothesis corresponds to $\delta = 0$, and we considered various forms for $d(\cdot)$ to investigate power. We only considered the test based on $\tilde{I}_n/\tilde{\omega}_n$, labelled LMP, as preliminary simulation results showed that the tests based on $\hat{I}_n^*$ had similar or better performances than the test based on $\hat{I}_n$, and $\hat{\omega}_n$ is computationally less demanding than $\tilde{\omega}_n$. We compared it to the test of Lavergne and Vuong (2000) (hereafter LV) and the test of Delgado and González Manteiga (2001) (hereafter DGM). The latter is based on the Cramer-von-Mises statistic

$$\sum_{i=1}^n \left[ \sum_{j=1}^n \hat{u}_j \hat{f}_j 1 \{ W_j \leq W_i \} 1 \{ X_j \leq X_i \} \right]^2.$$

As its distribution under $H_0$ is not asymptotically pivotal, critical values must be obtained by wild bootstrapping. To compute bootstrap critical values, we used 199 bootstrap replications and the two-point distribution

$$P \left( \eta_1 = \frac{1 - \sqrt{5}}{2} \right) = \frac{5 + \sqrt{5}}{10}, \quad P \left( \eta_1 = \frac{1 + \sqrt{5}}{2} \right) = \frac{5 - \sqrt{5}}{10}.$$

We also applied this method to obtain small sample critical values for LV test as well as our test. For all tests, each time a kernel appears, we used the normal density. The bandwidth parameters are set to $g = C_1 n^{-1/6}$ and $h = C_2 n^{-2.1/6}$, and we let $C_1$ and $C_2$ vary to investigate the sensitivity of our results to the smoothing parameters choice. To study the influence of $\psi(\cdot)$ on our test, we considered $\psi(x) = l(\|x\|)$, where $l(\cdot)$ is a triangular or normal density, each with a second moment equal to one.

Figures 1 and 2 reports the empirical level of the various tests for $n = 100$ based on 5000 replications when we let $C_1$, $C_2$, and $q$ vary. For our test, bootstrapping yields more accurate rejection levels than the asymptotic normal critical values for any bandwidth factors $C_1$ and $C_2$ and dimension $q$. The choice of $\psi(\cdot)$ does not influence the results. The empirical level of LV test is much more sensitive to the bandwidth and the dimension. The empirical level of the
1. Empirical rejections under $H_0$ as a function of the bandwidth, $n = 100$.

2. Empirical rejections under $H_0$ as a function of the bandwidth, $n = 100$. 
DGM test is close to the nominal one for a low dimension $q$ and large enough bandwidth $g$, but decreases with increasing $q$ and increases with decreasing bandwidth $g$.

We also investigated how power varies with different alternatives as specified by $d(·)$. We first focus on a quadratic alternative, where $d(X) = (X’β - 1)^2/\sqrt{2}$, with $β = (1, 1, \ldots, 1)/\sqrt{q}$. Figure 3 reports power curves of the different tests for the quadratic alternative, $n = 100$, and a nominal level of 10% based on 2500 replications. We also report the power of a Fisher test based on a linear specification in the components of $X$. The power of our test, as well as the one of LV test, increases when the bandwidth factor $C_2$ increases, in line with theoretical findings. Our test always perform as well or better than LV test, but for $q = 1$ and $C_2 = 1$. These tests, as well as DGM test, perform better than the Fisher test. For a low dimension, i.e. $q = 1$, there is no clear ranking of the DGM and our test depending on the bandwidth. For larger dimensions, $q = 3$ or $5$, our test dominates DGM test. In Figure 4, we let $n$ vary for a dimension $q = 5$. The power of all tests improve, but our main qualitative findings are not affected. It is noteworthy that the power advantage of our test compared to LV test become more pronounced as $n$ increases. In Figure 5, we considered a sine alternative defined as $d(X) = \sum_{j=1}^{q} \sin(\gamma X_j)$ for $\gamma = 1.5$ or $3$. The ranking

![Graphs showing empirical rejection rates for different dimensions and bandwidths](image-url)
of the different tests heavily depends on the frequency and the dimension of \( X \). For a low frequency alternative, i.e. \( \gamma = 1.5 \), our main findings remain unchanged. While DGM test is best for a low dimension, its power decreases a lot when increasing the dimension of variables under test and/or the frequency of the alternative. The power of our test is affected when increasing \( q \), but to a lesser extent. For a high frequency alternative, i.e. \( \gamma = 3 \), the LV test always dominates, as smoothing on the variables under test allows to adapt better to such alternatives.

We also considered the case of a discrete \( X \). We generated data following

\[
Y = W^3 - W + \delta d(W) \mathbf{1}\{X = 1\} + \varepsilon
\]

where \( W \) follows a univariate standard normal, \( \varepsilon \sim \mathcal{N}(0, 4) \), and \( X \) is Bernoulli with probability of success 0.6. In this setup, testing the significance of \( X \) is equivalent to testing the equality of the regression curves on \( Y \) on \( W \) when \( X \) equals 0 or 1. We considered two competitors to our test: the test proposed by Lavergne (2001), which is similar to our test with the main difference that \( \psi(\cdot) \) is the indicator function, i.e. \( \psi(X_i - X_j) = \mathbf{1}\{X_i = X_j\} \); and the test of Neumeyer and Dette (2003) (hereafter ND), which is similar in spirit to the DGM test. Other details of the simulations are similar to above. Figure 6 show that bootstrap yield accurate rejection levels.

Figure 7 report power of the tests against the quadratic alternative \( d(W) = W^2 - 1 \) and the sine alternative \( d(W) = \sin(1.5W) \). Our test and Lavergne’s one have basically the same power in both cases. Under a quadratic alternative, ND test is more powerful, while under a sine alternative, our test outperforms ND test for a moderate (\( C_2 = 2 \)) or large (\( C_2 = 4 \)) bandwidth.

5. Conclusion

We have developed a testing procedure for the significance of covariates in a nonparametric regression. Smoothing is entertained only for the covariates under...
the null hypothesis. The resulting test statistic is asymptotically pivotal, and wild bootstrap can be used to obtain critical values in small and moderate samples. The test is versatile, as it applies whether the covariates under test are continuous and/or discrete. Simulations reveal that our test outperforms its competitors in many situations, and especially when the dimension of covariates is large.
6. Proofs

We here provide the proofs of the main results. Technical lemmas are relegated to the Appendix. We let $F_X[\delta](u) = \mathbb{E}[e^{-2\pi i \langle X, u \rangle} \delta(X)]$, $u \in \mathbb{R}^q$, for any integrable function $\delta(X)$. Moreover, for any index set $I$ not containing $i$ with cardinality $|I|$, let

$$\tilde{f}_i^I = (n - |I| - 1)^{-1} \sum_{k \neq i, k \notin I} L_{n,ik}.$$

This is consistent with the notation $\tilde{f}_i$, in which case $I$ is the empty set.
6.1. Proof of Theorem 1

We first consider the case $I_n = \tilde{I}_n$. Next, we study the difference between $\tilde{I}_n$ and $I_n$ and hence deduce the result for $I_n = \tilde{I}_n$.

Case $I_n = \tilde{I}_n$. Consider the decomposition

$$I_n = \frac{1}{n^2} \sum_a (u_i - u_k)(u_j - u_l)^2 L_{nik}L_{njl}K_{nij}\psi_{ij}$$

$$+ 2 \frac{1}{n^2} \sum_a (u_i - u_k)(r_j - r_l)L_{nik}L_{njl}K_{nij}\psi_{ij}$$

$$+ \frac{1}{n^2} \sum_a (r_i - r_k)(r_j - r_l)L_{nik}L_{njl}K_{nij}\psi_{ij}$$

$$= I_1 + 2I_2 + I_3,$$

where

$$I_1 = \frac{n - 2}{n - 3} \sum_a u_i u_j f_i f_j K_{nij}\psi_{ij} + 2 \frac{n - 2}{n - 3} \sum_a u_i (\hat{f}_i^2 - f_i) u_j f_j K_{nij}\psi_{ij}$$

$$+ \frac{n - 2}{n - 3} \sum_a u_i (\hat{f}_i^2 - f_i) u_j (\hat{f}_j^2 - f_j) K_{nij}\psi_{ij} - \frac{2}{n^3} \sum_a u_i f_i u_l L_{njl}K_{nij}\psi_{ij}$$

$$- \frac{2}{n^3} \sum_a u_i L_{nik}L_{njl}K_{nij}\psi_{ij} - \frac{1}{n^4} \sum_a u_i u_j L_{nik}L_{njl}K_{nij}\psi_{ij}$$

$$= \frac{n - 2}{n - 3} [I_{0n} + 2I_{1,1} + I_{1,2}] - 2I_{1,3} - 2I_{1,4} + I_{1,5} - I_{1,6},$$

and

$$I_2 = \frac{1}{n^3} \sum_a u_i f_i(r_j - r_l)L_{njl}K_{nij}\psi_{ij} + \frac{1}{n^3} \sum_a u_i (\hat{f}_i^2 - f_i)(r_j - r_l)L_{njl}K_{nij}\psi_{ij}$$

$$- \frac{1}{n^4} \sum_a u_i (r_i - r_l)L_{nij}L_{njl}K_{nij}\psi_{ij} = I_{2,1} + I_{2,2} - I_{2,3},$$

In Proposition 1 we prove that, under $H_0$, $I_{0n}$ is asymptotically centered Gaussian with variance $\omega^2$, while in Proposition 2 we prove that, under $H_{1n}$, $I_{0n}$ is asymptotically Gaussian with mean $\mu$ and variance $\omega^2$ provided $\delta_n^2 nh^{p/2}$ converges to some positive real number. In Propositions 3 and 4 we show that all remaining terms in the decomposition of $I_n$ are asymptotically negligible.

**Proposition 1.** Under the conditions of Theorem 1, $nh^{p/2}I_{0n} \rightarrow_d N(0, \omega^2)$ under $H_0$.

**Proof.** Let us define the martingale array $\{S_{n,m}, F_{n,m}, 1 \leq m \leq n, n \geq 1\}$ where $S_{n,1} = 0$, and
Proof. Let $\varepsilon_i = Y_i - \mathbb{E}[Y_i | W_i, X_i]$ and let us decompose

$$nh^{p/2} I_{0n} = \frac{h^{p/2}}{n-1} \sum_{i=1}^{n} \sum_{j \neq i} u_i f_i u_j f_j K_{nij} \psi_{ij}$$

and $\mathcal{F}_{n,m}$ is the $\sigma$-field generated by $\{W_1, \ldots, W_n, X_1, \ldots, X_n, Y_1, \ldots, Y_m\}$. Thus $nh^{p/2} I_{0n} = S_{n,n}$. Also define

$$V_n^2 = \sum_{i=2}^{n} E \left[G_{n,i}^2 \mid \mathcal{F}_{n,i-1}\right] = \frac{4h^p}{(n-1)^2} \sum_{i=2}^{n} \sum_{j=1}^{i-1} \sum_{k=1}^{j-1} u_j f_j u_k f_k K_{nij} K_{nik} \psi_{ij} \psi_{ik}$$

where $\sigma^2 = \sigma^2(W_i, X_i)$. We can decompose $V_n^2$ as

$$V_n^2 = \frac{4h^p}{(n-1)^2} \sum_{i=2}^{n} \sum_{j=1}^{i-1} \sum_{k=1}^{j-1} u_j f_j u_k f_k K_{nij} K_{nik} \psi_{ij} \psi_{ik}$$

$$= \frac{4h^p}{(n-1)^2} \sum_{i=2}^{n} \sum_{j=1}^{i-1} \sum_{k=1}^{j-1} \sigma^2 \psi_{ij}^2 \psi_{ik}^2$$

$$+ \frac{8h^p}{(n-1)^2} \sum_{i=3}^{n} \sum_{j=2}^{i-1} \sum_{k=1}^{j-1} \sigma^2 \psi_{ij}^2 \psi_{ik}^2 = A_n + B_n.$$

The result follows from the Central Limit Theorem for martingale arrays, see Corollary 3.1 of Hall and Heyde (1980). The conditions required for Corollary 3.1 of Hall and Heyde (1980), among which $V_n^2 \xrightarrow{p} \omega^2$, are checked in Lemma 2 below. Its proof is provided in the Appendix.

Lemma 2. Under the conditions of Proposition 1,

1. $A_n \xrightarrow{p} \omega^2$,
2. $B_n \xrightarrow{p} 0$,
3. the martingale difference array $\{G_{n,i}, \mathcal{F}_{n,i}, 1 \leq i \leq n\}$ satisfies the Lindeberg condition

$$\forall \varepsilon > 0, \sum_{i=2}^{n} \mathbb{E} \left[G_{n,i}^2 I (|G_{n,i}| > \varepsilon) \mid \mathcal{F}_{n,i-1}\right] \xrightarrow{p} 0. \quad \square$$

Proposition 2. Under the conditions of Theorem 1 and $H_{1n}$, if $\delta_n^{2} nh^{p/2} \xrightarrow{d} C$ with $0 < C < \infty$, $nh^{p/2} I_{0n} \xrightarrow{d} N(C \mu, \omega^2)$.

Proof. Let $\varepsilon_i = Y_i - \mathbb{E}[Y_i | W_i, X_i]$ and let us decompose

$$nh^{p/2} I_{0n} = \frac{h^{p/2}}{n-1} \sum_{i=1}^{n} \sum_{j \neq i} u_i f_i u_j f_j K_{nij} \psi_{ij}$$

$$= \frac{h^{p/2}}{n-1} \sum_{i=1}^{n} \sum_{j \neq i} \delta_n d_i + \varepsilon_i \right) f_i \left( \delta_n d_j + \varepsilon_j \right) f_j K_{nij} \psi_{ij}$$
By Proposition 1, \( C_n \overset{d}{\rightarrow} \mathcal{N}(0, \omega^2) \). As for \( C_n \), we have
\[
\mathbb{E}[C_n] = \delta_n^2 n h^{p/2} \mathbb{E}[d_1 f_1 d_2 f_2 K_{nij} \psi_{ij}] = \delta_n^2 n h^{p/2} \mu_n.
\]
By repeated application of Fubini’s Theorem, Fourier Inverse formula, Dominated Convergence Theorem, and Parseval’s identity, we obtain
\[
\mu_n = \mathbb{E}[d_1 f_2 d_1 f_2 K_{n12} \psi_{12}]
\]
\[
= \mathbb{E} \left[ \int \int \varrho(w_1, X_1) f(w_1) \varrho(w_2, X_2) f(w_2) \times h^{-p} K \left( \frac{w_1 - w_2}{h} \right) dw_1 dw_2 \psi(X_1 - X_2) \right]
\]
\[
= \mathbb{E} \left[ \int \mathcal{F}[\varrho(\cdot, X_1) f(\cdot)](t) \mathcal{F}[\varrho(\cdot, X_2) f(\cdot)](-t) \mathcal{F}[K](ht) dt \psi(X_1 - X_2) \right]
\]
\[
= \mathbb{E} \left[ \int \mathcal{F}[\varrho(\cdot, X_1) f(\cdot)](t) \mathcal{F}[\varrho(\cdot, X_2) f(\cdot)](-t) \mathcal{F}[\psi](u) du \right] f^2(w) dw
\]
\[
= \int \mathcal{F}[\varrho(w, \cdot)](u) \mathcal{F}[\varrho(w, \cdot)](-u) \mathcal{F}[\psi](u) du \int f^2(w) dw = \mu,
\]
where \( \varrho(w, x) = d(w, x) \pi(w | \cdot) \). Moreover,
\[
\text{Var}[C_n] \leq \frac{4 \delta_n^4 h^p}{(n-1)^2} \sum_a \mathbb{E} \left[ d_i^2 f_i d_k f_k K_{nij} \psi_{ij} \right]
\]
\[
+ \frac{2 \delta_n^4 h^p}{(n-1)^2} \sum_a \mathbb{E} \left[ d_i^2 f_i d_k f_k K_{nij} \psi_{ij}^2 \right]
\]
\[
+ \frac{4 \delta_n^4 h^p}{(n-1)^2} \sum_a \mathbb{E} \left[ d_i f_i d_j f_j K_{njk} \psi_{jk} \psi_{ij} \right]
\]
\[
+ \frac{4 \delta_n^4 h^p}{(n-1)^2} \sum_a \mathbb{E} \left[ d_i^2 f_i \varepsilon_i f_i^2 K_{nij} \psi_{ij}^2 \right]
\]
\[
= O \left( \delta_n^4 n h^p \right) + O \left( \delta_n^4 \right) + O \left( \delta_n^4 n h^p \right) + O \left( \delta_n^4 \right).
\]
Therefore \( C_n = C \mu_n + O_p(\delta_n n^{1/2} h^{p/2}) \xrightarrow{p} C \mu \), and the desired result follows.
Proposition 3. Under the conditions of Theorem 1,
(i) $nh^{p/2}I_{1,3} = \delta_n \sqrt{n}h^{p/2}O_p(1) + o_p(1)$,
(ii) $nh^{p/2}I_{1,5} = o_p(1)$,
(iii) $nh^{p/2}I_{1,6} = \delta_n^2 nh^{p/2}o_p(1) + o_p(1)$,
(iv) $nh^{p/2}I_{2,1} = \delta_n \sqrt{n}h^{p/2}o_p(1) + \delta_n \sqrt{n}h^{p/2}g^*O_p(1) + o_p(1)$,
(v) $nh^{p/2}I_{2,3} = o_p(1)$,
(vi) $nh^{p/2}I_3 = nh^{p/2}O_p(g^{2*}) + o_p(1)$.

Proposition 4. Under the conditions of Theorem 1,
(i) $nh^{p/2}I_{1,1} = \delta_n^2 nh^{p/2}o_p(1) + \delta_n \sqrt{n}h^{p/2}o_p(1) + o_p(1)$,
(ii) $nh^{p/2}I_{1,2} = \delta_n^2 nh^{p/2}o_p(1) + \delta_n \sqrt{n}h^{p/2}o_p(1) + o_p(1)$,
(iii) $nh^{p/2}I_{1,4} = \delta_n^2 nh^{p/2}o_p(1) + \delta_n \sqrt{n}h^{p/2}o_p(1) + (ng^*)^{-1/2}o_p(1) + o_p(1)$,
(iv) $nh^{p/2}I_{2,2} = \delta_n^2 nh^{p/2}o_p(1) + \delta_n \sqrt{n}h^{p/2}o_p(1) + o_p(1)$.

The proofs of the above propositions follow the ones in Lavergne and Vuong (2000). For illustration, we provide in the Appendix the proofs of the first statements of each proposition.

Case $I_n = \hat{I}_n$. We have the following decomposition

$$n^{(4)} \hat{I}_n = n(n - 1)^3 \tilde{I}_n - n^{(3)} V_{1n} - 2n^{(3)} V_{2n} + n^{(2)} V_{3n} \quad (2)$$

where

$$V_{1n} = \frac{1}{n^{(3)}} \sum_a (Y_i - Y_k)(Y_j - Y_k) \ L_{niki} L_{njkj} K_{nij} \psi_{ij},$$

$$V_{2n} = \frac{1}{n^{(3)}} \sum_a (Y_i - Y_j)(Y_j - Y_k) \ L_{niji} L_{njkj} K_{nij} \psi_{ij},$$

and

$$V_{3n} = \frac{1}{n^{(2)}} \sum_a (Y_i - Y_j)^2 L_{niji}^2 K_{nij} \psi_{ij}.$$

Hence, to show that $\hat{I}_n$ has the same asymptotic distribution as $\tilde{I}_n$, it is sufficient to investigate the behavior of $V_{1n}$ to $V_{3n}$. Using $Y_i = r_i + u_i$, it is straightforward to see that the dominating terms in $V_{1n}$, $V_{2n}$ and $V_{3n}$ are

$$V_{13} = \frac{1}{n^{(3)}} \sum_a (r_i - r_k)(r_j - r_k) \ L_{niki} L_{njkj} K_{nij} \psi_{ij},$$

$$V_{23} = \frac{1}{n^{(3)}} \sum_a (r_i - r_j)(r_j - r_k) \ L_{niji} L_{njkj} K_{nij} \psi_{ij},$$

$$V_{33} = \frac{1}{n^{(2)}} \sum_a (r_i - r_j)^2 L_{niji}^2 K_{nij} \psi_{ij},$$

respectively. Now

$$E[|V_{13}|] = E[|(r_i - r_k)(r_j - r_k) \ L_{niki} L_{njkj} K_{nij}|]$$

$$= O(g^{-p}) E[|r_i - r_k| L_{niki} E[|r_j - r_k| K_{nij} | Z_i, Z_k]] = O(g^{-p}),$$
\[ E[|V_{23}|] = E[| \{ \hat{r}_i - r_j \} \{ \hat{r}_j - r_k \} L_{nij} L_{njk} N_{nij} |] \\
= E[ E[| \{ \hat{r}_j - r_k \} L_{njk} | Z_j] | \{ \hat{r}_i - r_j \} L_{nij} N_{nij} ]] \\
= o(1) E[| \{ \hat{r}_i - r_j \} L_{nij} N_{nij} |] = o(g^{-p}) \\
E[|V_{33}|] = E \left[ (r_i - r_j)^2 L_{nij}^2 | K_{nij} \right] \\
= O(g^{-2p}) E \left[ (r_i - r_j)^2 K_{nij} \right] = o(g^{-2p}). \]

It then follows that \( nh^{p/2}(\hat{T}_n - T_n) = O_p(h^{p/2}g^{-p}) \) which is negligible if \( h/g^2 \to 0 \).

The asymptotic irrelevance of the above diagonal terms thus require more restrictive relationships between the bandwidths \( h \) and \( g \). For the sake of comparison, recall that Fan and Li (1996) impose \( h^{p+q}g^{-2p} \to 0 \) while Lavergne and Vuong (2000) require only \( h^{p+q}g^{-p} \to 0 \). Since we do not smooth the covariates \( X \), we are able to further relax the restriction between the two bandwidths.

### 6.2. Proof of Corollary 1

It suffices to prove \( \omega_n^2 - \omega^2 = o_p(1) \) with \( \omega_n^2 \) any of \( \hat{\omega}_n^2 \) or \( \hat{\omega}_n^2 \). First we consider the case \( \omega_n^2 = \hat{\omega}_n^2 \). A direct approach would consist in replacing the definition of \( \hat{u}_i \hat{f}_i \) and \( \hat{u}_j \hat{f}_j \), writing \( \hat{\omega}_n^2 \) as a \( U \)-statistic of order 6, and studying its mean and variance. A shorter approach is based on empirical process tools. The price to pay is the stronger condition \( n^{7/8}g^p/\ln n \to \infty \) instead of \( ng^p \to \infty \). Let \( \Delta \hat{f}_i = \hat{f}_i - f_i, \Delta \tilde{f}_i = \tilde{f}_i - f_i \), and write

\[
\hat{u}_i \hat{f}_i = u_i f_i + Y_i \Delta \hat{f}_i - \Delta \tilde{f}_i. \tag{3}
\]

**Lemma 3.** Under Assumption 1, if \( r(\cdot) f(\cdot) \in \mathcal{U}^p, L(\cdot) \) is a function of bounded variation, \( g \to 0 \), and \( n^{7/8}g^p/\ln n \to \infty \), then

\[
\sup_{1 \leq i \leq n} \{|\Delta \tilde{f}_i| + |\Delta \hat{f}_i|\} = o_p(1).
\]

The proof relies on the uniform convergence of empirical processes and is provided in the Appendix. Now proceed as follows: square Equation (3), replace \( \hat{u}_i^2 \hat{f}_i^2 \) in the definition of \( \hat{\omega}_n^2 \), and use Lemma 3 to deduce that

\[
\hat{\omega}_n^2 = \frac{2h^p}{n^{(2)}} \sum_{a(2)} u_i^2 f_i^2 u_j^2 f_j^2 K_{nij}^2 \psi_{ij}^2 + o_p(1).
\]

Elementary calculations of mean and variance yield

\[
\frac{2h^p}{n^{(2)}} \sum_{a(2)} u_i^2 f_i^2 u_j^2 f_j^2 K_{nij}^2 \psi_{ij}^2 - \omega^2 = o_p(1),
\]

and thus \( \omega_n^2 - \omega^2 = o_p(1). \)

To deal with \( \hat{\omega}_n^2 \), note that \( \omega_n^2 - \hat{\omega}_n^2 \) consists of “diagonal” terms plus a term which is \( O(n^{-1} \omega_n^2) \). By tedious but rather straightforward calculations, one can check that such diagonal terms are each of the form \( n^{-1}g^{-p} \) times a \( U \)-statistic which is bounded in probability. Hence \( \omega_n^2 - \hat{\omega}_n^2 = o_p(1). \)
6.3. Proof of Theorem 2

Let $\mathcal{Z}$ denote the sample $(Y_i, W_i, X_i), 1 \leq i \leq n$. Since the limit distribution is continuous, it suffices to prove the result pointwise by Polya’s theorem. Hence we show that $\forall t \in \mathbb{R}, \mathbb{P}[nh^{p/2}I^*_n/\omega^*_n \leq t | \mathcal{Z}] - \Phi(t) = o_p(1)$.

First, we consider the case $I^*_n = I_n$. Consider

$$I^*_{n, LV} = \frac{1}{n^{(4)}} \sum_a (\eta_i \hat{u}_i - \eta_k \hat{u}_k) (\eta_j \hat{u}_j - \eta_l \hat{u}_l) L_{nij} L_{njl} K_{nij} \psi_{ij}$$

$$+ \frac{2}{n^{(4)}} \sum_a (\eta_i \hat{u}_i - \eta_k \hat{u}_k) (\hat{r}_j - \hat{r}_l) L_{nij} L_{njl} K_{nij} \psi_{ij}$$

$$+ \frac{1}{n^{(4)}} \sum_a (\hat{r}_i - \hat{r}_k) (\hat{r}_j - \hat{r}_l) L_{nij} L_{njl} K_{nij} \psi_{ij}$$

$$= I^*_1 + 2I^*_2 + I^*_3$$

where we can further decompose

$$I^*_1 = \frac{1}{n^{(4)}} \sum_a \eta_i \hat{u}_i \eta_j \hat{u}_j L_{nij} L_{njl} K_{nij} \psi_{ij}$$

$$- \frac{2}{n^{(4)}} \sum_a \eta_j \hat{u}_j \eta_k \hat{u}_k L_{nij} L_{njl} K_{nij} \psi_{ij}$$

$$+ \frac{1}{n^{(4)}} \sum_a \eta_k \hat{u}_k \eta_l \hat{u}_l L_{nij} L_{njl} K_{nij} \psi_{ij}$$

$$= I^*_{1,1} + I^*_{1,2} + I^*_{1,3}$$

with

$$I^*_{1,1} = \frac{(n-1)^2}{(n-3)(n-4)} \times \frac{1}{n^{(2)}} \sum_a \eta_i \hat{u}_i \eta_j \hat{u}_j \hat{f}_i \hat{f}_j L_{nij} K_{nij} \psi_{ij}$$

$$- \frac{2}{n-4} \times \frac{1}{n^{(3)}} \sum_a \eta_i \hat{u}_i \eta_j \hat{u}_j L_{nij} L_{nij} K_{nij} \psi_{ij}$$

$$- \frac{1}{n-4} \times \frac{1}{n^{(3)}} \sum_a \eta_j \hat{u}_j \eta_k \hat{u}_k L_{nij} L_{nij} K_{nij} \psi_{ij}$$

$$- \frac{1}{(n-3)(n-4)} \times \frac{1}{n^{(2)}} \sum_a \eta_i \hat{u}_i \eta_j \hat{u}_j L^2_{nij} K_{nij} \psi_{ij}$$

$$= I^*_{0n} - \frac{2}{n-4} I^*_{1,1,1} - \frac{1}{n-4} I^*_{1,1,2} - \frac{1}{(n-3)(n-4)} I^*_{1,1,3}.$$
= \mathbb{P}\left( \frac{nh^{p/2}I_{0n}^*}{\hat{\omega}_n} + \frac{nh^{p/2}D_n^*}{\hat{\omega}_n} + \frac{nh^{p/2}(I_{0n}^* + D_n^*)}{\hat{\omega}_n}\left(\frac{\hat{\omega}_n}{\hat{\omega}_n} - 1\right) \leq t \mid Z \right).

It thus suffices to prove that
\[
\mathbb{P}\left( \frac{nh^{p/2}I_{0n}^*}{\hat{\omega}_{n,FL}} \leq t \right) - \Phi(t) \rightarrow 0 \quad \forall t \in \mathbb{R},
\]
\[
\frac{nh^{p/2}D_n^*}{\hat{\omega}_{n,FL}} = o_p(1), \quad \text{and} \quad \frac{nh^{p/2}(I_{0n}^* + D_n^*)}{\hat{\omega}_{n,FL}}\left(\frac{\hat{\omega}_{n,FL}}{\hat{\omega}_{n,FL}} - 1\right) = o_p(1).
\]

The first result is stated below.

**Proposition 5.** Under the conditions of Theorem 2, conditionally on the observed sample, the statistic \( nh^{p/2}I_{0n}^*/\hat{\omega}_{n,FL} \) converges in law to a standard normal distribution.

**Proof.** We proceed as in the proof of Proposition 1 and check the conditions for a CLT for martingale arrays, see Corollary 3.1 of Hall and Heyde (1980). Define the martingale array \( \{S_{n,m}, \mathcal{F}_{n,m}, 1 \leq m \leq n, n \geq 1\} \) where \( \mathcal{F}_{n,m} \) is the \( \sigma \)-field generated by \( \{Z, \eta_1, \ldots, \eta_m\} \), \( S_{n,1}^* = 0 \), and \( S_{n,m}^* = \sum_{i=1}^m G_{n,i}^* \) with
\[
G_{n,i}^* = \frac{2h^{p/2}}{n-1}\eta_i u_i \sum_{j=1}^{i-1} \eta_j \hat{u}_j \hat{f}_j \hat{f}_j K_{nij} \psi_{ij}.
\]

Then
\[
I_{0n}^* = \frac{(n-1)^2}{(n-3)(n-4)} \times \frac{1}{n(n-1)} \sum_{\alpha} \eta_\alpha u_\alpha \eta_\alpha u_\alpha f_\alpha \hat{f}_\alpha f_\alpha K_{nij} \psi_{ij} = \frac{(n-1)^2}{(n-3)(n-4)} S_{n,n}^*.
\]

Now consider
\[
V_n^{2*} = \sum_{i=2}^n \mathbb{E}\left[G_{n,i}^{2*} \mid \mathcal{F}_{n,i-1}^*\right]
\]
\[
= \frac{4h^p}{(n-1)^2} \sum_{i=2}^n \sum_{j=1}^{i-1} \sum_{k=1}^{i-1} \hat{u}_i^2 \eta_{ij} \eta_{ik} \hat{u}_j \hat{f}_j \hat{f}_j \hat{f}_j \hat{f}_j K_{nij} K_{nik} \psi_{ij} \psi_{ik}
\]
\[
= \frac{4h^p}{(n-1)^2} \sum_{i=2}^n \sum_{j=1}^{i-1} \hat{u}_i^2 \eta_{ij} \eta_{ij} \hat{u}_j \hat{f}_j \hat{f}_j \hat{f}_j \hat{f}_j K_{nij}^2 \psi_{ij} \psi_{ij}
\]
\[
+ \frac{8h^p}{(n-1)^2} \sum_{i=3}^n \sum_{j=2}^{i-1} \sum_{k=1}^{i-1} \hat{u}_i^2 \eta_{ij} \eta_{ij} \hat{u}_j \hat{f}_j \hat{f}_j \hat{f}_j \hat{f}_j K_{nij} \psi_{ij} \psi_{ik}
\]
\[
= A_n^* + B_n^*.
\]
Note that $\mathbb{E}[A_{n}^{*} | \mathcal{Z}] = [n/(n-1)]\mathbb{E}[\zeta_{n}^{2}]$ and that

$$\text{Var} \left[ A_{n}^{*} | \mathcal{Z} \right] \leq \frac{16h^{2p}\mathbb{E} \left[ \eta^{4} \right]}{(n-1)^{2}} \sum_{i=2}^{n} \sum_{i' = 2}^{n} \sum_{j=1}^{n-1} \sum_{j' = 2}^{n-1} \hat{u}_{i}^{4} \hat{u}_{i'}^{4} \hat{f}_{i}^{2} \hat{f}_{i'}^{2} \hat{f}_{j}^{2} \hat{f}_{j'}^{2} K_{nij}^{2} K_{nij'}^{2} \psi_{ij}^{2} \psi_{i'j'}^{2}$$

$$\leq \frac{16h^{2p}\mathbb{E} \left[ \eta^{4} \right]}{(n-1)^{4}} \sum_{i=2}^{n} \sum_{j=1}^{n-1} \sum_{j' = 2}^{n-1} \hat{u}_{i}^{4} \hat{u}_{j}^{2} \hat{f}_{i}^{2} \hat{f}_{j}^{2} K_{nij}^{2} K_{nij'}^{2}$$

$$+ \frac{32h^{2p}\mathbb{E} \left[ \eta^{4} \right]}{(n-1)^{4}} \sum_{i=3}^{n-1} \sum_{j' = 2}^{n-1} \sum_{j = 1}^{n-1} \hat{u}_{i}^{2} \hat{u}_{j}^{2} \hat{f}_{i}^{2} \hat{f}_{j}^{2} K_{nij}^{2} K_{nij'}^{2} \psi_{ij}^{2} \psi_{i'j'}^{2}$$

$$= Q_{1n} + Q_{2n}.$$

On the other hand,

$$\mathbb{E}[B_{n}^{2} | \mathcal{Z}]$$

$$= \frac{64h^{2p}}{(n-1)^{4}} \sum_{i=2}^{n} \sum_{i' = 2}^{n} \sum_{j=2}^{n} \sum_{j' = 2}^{n-1} \hat{u}_{i}^{4} \hat{u}_{i'}^{2} \hat{u}_{j}^{2} \hat{u}_{j'}^{2} \hat{f}_{i}^{2} \hat{f}_{i'}^{2} \hat{f}_{j}^{2} \hat{f}_{j'}^{2} K_{nij}^{2} K_{nij'}^{2} K_{nijk}^{2} K_{nijk'}^{2} \psi_{ij}^{2} \psi_{i'j'}^{2}$$

$$\leq \frac{128h^{2p}}{(n-1)^{4}} \sum_{i=3}^{n} \sum_{j' = 2}^{n-1} \sum_{j = 1}^{n-1} \hat{u}_{i}^{2} \hat{u}_{j}^{2} \hat{u}_{j}^{2} \hat{u}_{k}^{2} \hat{f}_{i}^{2} \hat{f}_{i}^{2} \hat{f}_{j}^{2} \hat{f}_{j}^{2} K_{nij}^{2} K_{nij'}^{2} K_{nijk}^{2} K_{nijk'}^{2} \psi_{ij}^{2} \psi_{i'j'}^{2}$$

$$= Q_{3n} + Q_{4n}.$$

Finally the Lindeberg condition involves

$${\sum}_{i=1}^{n} \mathbb{E} \left[ G_{n,i}^{*} I \left( \left| G_{n,i}^{*} \right| > \varepsilon \right) | \mathcal{F}_{n,i-1}^{*} \right]$$

$$\leq \frac{1}{\varepsilon^{4}} \sum_{i=1}^{n} \mathbb{E} \left[ G_{n,i}^{*} | \mathcal{F}_{n,i-1}^{*} \right]$$

$$\leq \frac{16h^{2p}\mathbb{E} \left[ \eta^{4} \right]}{(n-1)^{2}} \sum_{i=2}^{n} \sum_{i' = 2}^{n} \sum_{j=1}^{n-1} \sum_{j' = 2}^{n-1} \hat{u}_{i}^{4} \hat{u}_{i'}^{4} \hat{f}_{i}^{2} \hat{f}_{i'}^{2} \hat{f}_{j}^{2} \hat{f}_{j'}^{2} K_{nij}^{2} K_{nij'}^{2} K_{nijk}^{2} K_{nijk'}^{2} \psi_{ij}^{2} \psi_{i'j'}^{2}$$

$$\leq \frac{16h^{2p}\mathbb{E} \left[ \eta^{4} \right]}{(n-1)^{4}} \sum_{i=2}^{n} \sum_{j=1}^{n-1} \sum_{j' = 2}^{n-1} \hat{u}_{i}^{4} \hat{f}_{i}^{4} \hat{f}_{j}^{2} K_{nij}^{4} K_{nij'}^{2}$$

$$+ \frac{32h^{2p}\mathbb{E} \left[ \eta^{4} \right]}{(n-1)^{4}} \sum_{i=3}^{n} \sum_{j' = 2}^{n-1} \sum_{j = 1}^{n-1} \hat{u}_{i}^{2} \hat{u}_{j}^{2} \hat{f}_{i}^{2} \hat{f}_{j}^{2} K_{nij}^{2} K_{nij'}^{2} \psi_{ij}^{2} \psi_{i'j'}^{2}$$

$$= Q_{5n} + Q_{6n}.$$
\( k = 1, 2 \in \{1, 2\} \),
\[
\hat{u}_{ij}^{2k} \leq 3^{2k-1} \left( u_i^{2k} f_i^{2k} + Y_i^{2k} f_i^{2k} \gamma_{1n} + \tilde{\gamma}_{2n}^{2k} \right)
\]
Indeed, \( \hat{u}_i \hat{f}_i = u_i f_i + Y_i f_i \hat{f}_i^{-1}(\hat{f}_i - f_i) + [\hat{f}_i \hat{f}_i - r_i f_i] = u_i f_i + Y_i f_i \gamma_{1i} - \gamma_{2i} \), where
\[
sup_{1 \leq i \leq n} |\gamma_{ji}| \leq \gamma_j \text{ and } \gamma_j = o_p(1) \text{ by Lemma 3. Hence}
\]
\[
\hat{u}_i^2 \hat{f}_i^2 \leq 3 \left( u_i^2 f_i^2 + Y_i f_i \gamma_{1n}^2 + \tilde{\gamma}_{2n}^2 \right)
\]

The inequality for \( k = 2 \) is obtained similarly. Using these inequalities, one can bound the expectations of \( |Q_{1n}| \) to \( |Q_{6n}| \) and thus show that \( |Q_{1n}| + \cdots + |Q_{6n}| = o_p(1) \).

Next we show (4). First we need the following.

**Proposition 6.** Under the conditions of Theorem 2, \( \bar{\omega}_{n,FL} \xrightarrow{p} 1 \) and \( \bar{\omega}_{n,FL} \xrightarrow{p} 1 \).

The proof uses the following result, which is proved in the Appendix.

**Lemma 4.** Under the conditions of Theorem 2, \( \sup_{1 \leq i \leq n} |\hat{u}_i^* \hat{f}_i - u_i^* f_i| = o_p(1) \),
where \( u_i^* = \eta_i u_i \) and
\[
\hat{u}_i^* = Y_i^* - \sum_{k \neq i} Y_{ik} L_{nij} \, \sum_{k \neq i} L_{nij}.
\]

**Proof.** Using Lemma 4, we have
\[
\hat{\omega}_{n,FL}^2 = \omega_{n,FL}^2 + o_p(1)
\]
where \( \omega_{n,FL}^2 = \frac{2h}{n_{ij}} \sum u_i^2 u_j^2 \hat{f}_i \hat{f}_j K_{n_{ij}}^2 \hat{\psi}_{ij}^2 \). Notice that \( \mathbb{E}[\omega_{n,FL}^2 | Z] = \bar{\omega}_{n,FL}^2 \) and that
\[
\text{Var} \left( \omega_{n,FL}^2 - \omega_{n,FL}^2 \right) = \text{Var} \left( \mathbb{E}[\omega_{n,FL}^2 | Z] \right) + \mathbb{E} \left[ \text{Var} \left( \omega_{n,FL}^2 | Z \right) \right]
\]
where the first term is zero and
\[
\text{Var} \left( \omega_{n,FL}^2 | Z \right) = \frac{8h^2 \mathbb{V} \text{ar} \left( \eta_i^2 \right)}{\left\{ \sum \hat{u}_i^4 \hat{f}_i^4 \hat{f}_j^4 K_{n_{ij}}^4 \hat{\psi}_{ij}^4 \right\}}
\]
Then,
\[
\frac{\hat{\omega}_{n,FL} \omega_{n,FL}^2}{\bar{\omega}_{n,FL}^2} = 1 + \frac{\hat{\omega}_{n,FL}^2 - \bar{\omega}_{n,FL}^2}{\bar{\omega}_{n,FL}^2} = 1 + \frac{o_p(1)}{\omega^2 (1 + o_p(1)) } = 1 + o_p(1).
\]
Since \( \hat{\omega}_{n,FL} - \bar{\omega}_{n,FL} \) contains only diagonal terms, we deduce that \( \hat{\omega}_{n,FL} / \bar{\omega}_{n,FL} \xrightarrow{p} 1 \).

We next have to bound \( D_n^* = I_{n,LV}^* - I_{n,FL}^* \). For this, let us decompose
\[
\hat{r}_i - \hat{r}_k = (\hat{r}_i - r_i) - (\hat{r}_k - r_k) + (r_i - r_k)
\]
and replace all such differences appearing in the definition of $D_n^*$. First, let us look at $I_3^*$ which does not contain any bootstrap variable $\eta$. We obtain

$$I_3^* = \frac{1}{n(4)} \sum_a (\hat{r}_i - r_i) \left( \hat{r}_j - r_j \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$= \frac{1}{n(4)} \sum_a (r_i - r_k) \left( r_j - r_l \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$+ \frac{1}{n(4)} \sum_a (\hat{r}_i - r_i) \left( \hat{r}_j - r_j \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$+ \frac{1}{n(4)} \sum_a (\hat{r}_k - r_k) \left( \hat{r}_l - r_l \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$+ \frac{2}{n(4)} \sum_a (\hat{r}_i - r_i) \left( r_j - r_l \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$- \frac{2}{n(4)} \sum_a (\hat{r}_k - r_k) \left( r_j - r_l \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$- \frac{2}{n(4)} \sum_a (\hat{r}_k - r_k) \left( \hat{r}_j - r_j \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

$$= I_{3,1}^* + I_{3,2}^* + I_{3,3}^* + 2I_{3,4}^* - 2I_{3,5}^* - 2I_{3,6}^*.$$}

Next, use the fact that

$$\hat{r}_i - r_i = (n - 1)^{-1} \tilde{f}_i^{-1} \sum_{i' \neq i} (Y_{i'} - r_i) L_{nii'}$$

$$= (n - 1)^{-1} \tilde{f}_i^{-1} \sum_{i' \neq i} (r_{i'} - r_i) L_{nii'} + (n - 1)^{-1} \tilde{f}_i^{-1} \sum_{i' \neq i} u_{i'} L_{nii'} \quad (5)$$

and further replace terms like $\hat{r}_i - r_i$. Among the terms $I_{3,1}^*$ to $I_{3,6}^*$, the term $I_{3,1}^*$ could be easily handled with existing results in Lavergne and Vuong (2000). Namely $nh^{p/2}I_{3,1}^* = nh^{p/2}O_p(q^2) + o_p(1)$ by Proposition 7 of Lavergne and Vuong (2000). For the other five terms we have to control the density estimates appearing in the denominators. For this purpose, let us introduce the notation $\Delta (f_i^l)^{-1} = (f_i^l)^{-1} - f_i^{-1}$ and write

$$\frac{n - |I|}{n - 1} \times \tilde{f}_i^{-1} = \left( \frac{n - |I|}{n - 1} \tilde{f}_i^{-1} - 1 \right) \left( f_i^l \right)^{-1} + \left( f_i^l \right)^{-1}$$

$$= \frac{1}{n(4)} \sum_a (r_j - r_l) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$

Then we obtain for instance

$$I_{3,5}^* = \frac{1}{n(4)} \sum_a (\hat{r}_k - r_k) \left( r_j - r_l \right) L_n \bar{L}_{nj} K_{ni} \psi_{ij}$$
\[
= \frac{1}{n^{(5)}} \sum_{a(4)} \sum_{k \neq k'} f^{-1}_k (r_{k'} - r_k) (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{n^{(5)}} \sum_{a(4)} \sum_{k \neq k'} \Delta \left( f^{-1}_k \hat{f}_k, j, l, k' \right)^{-1} (r_{k'} - r_k) (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{(n-1)n^{(5)}} \sum_{a(4)} \sum_{k \neq k'} (\hat{f}_k \hat{f}_k, j, l, k')^{-1} (L_{nik} + L_{njk} + L_{nlk} + L_{nk'k}) \\
\times (r_{k'} - r_k) (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{n^{(5)}} \sum_{a(4)} \sum_{k \neq k'} f^{-1}_k u_{kJ} (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{n^{(5)}} \sum_{a(4)} \sum_{k \neq k'} \Delta f^{-1}_k u_{kJ} (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{(n-1)n^{(5)}} \sum_{a(4)} \sum_{k \neq k'} (\hat{f}_k \hat{f}_k, j, l, k')^{-1} (L_{nik} + L_{njk} + L_{nlk} + L_{nk'k}) \\
\times u_{kJ} (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
= I_{4,5,1}^* + I_{4,5,2}^* + I_{4,5,3}^* + I_{4,5,4}^* + I_{3,5,5}^* + I_{3,5,6}^*.
\]

Next, if we consider for instance $I_{4,5,1}^*$ that contains only terms like $f^{-1}_i$ appearing from the decomposition 6, we obtain

\[
I_{4,5,1}^* = \frac{1}{n^{(5)}} \sum_{a(5)} f^{-1}_k (r_{k'} - r_k) (r_j - r_l) L_{nkk'} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{n^{(5)}} \sum_{a(4)} f^{-1}_k (r_i - r_k) (r_j - r_l) L_{nij}^2 L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{n^{(5)}} \sum_{a(4)} f^{-1}_k (r_j - r_k) (r_j - r_l) L_{njk} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
+ \frac{1}{n^{(5)}} \sum_{a(4)} f^{-1}_k (r_l - r_k) (r_j - r_l) L_{nlk} L_{nij} L_{njl} K_{nij} \psi_{ij} \\
= I_{4,5,1,1}^* + I_{3,5,1,1}^* + I_{3,5,1,3}^* + I_{3,5,1,4}^*
\]

where the terms $I_{3,5,1,2}^*$ to $I_{3,5,1,4}^*$ are called “diagonal terms”. Such terms require more restrictions on the bandwidths. Next, the terms containing terms like $\Delta(f^{-1}_i)^{-1}$ produced by the decomposition (6) can be treated like in the Propositions 8 to 11 of Lavergne and Vuong (2000). Finally, given that $I$ is finite and with fixed cardinal

\[
(n-1)^{-1} \tilde{f}_i^{-1} \left( \tilde{f}_i \right)^{-1} \sum_{k \in I} L_{nik} = O_p \left( n^{-1} g^{-p} \right) = o_p(1)
\]

given that $\|f^{-1}\|_\infty < \infty$. Therefore we can be easily handle the terms containing $(n-1)^{-1} \tilde{f}_i^{-1} \left( \tilde{f}_i \right)^{-1} \sum_{k \in I} L_{nik}$ by taking absolute values. Now let us investigate
the diagonal term $I^*_{3,5.1.2}$. We have

\[
\mathbb{E}[I^*_{3,5.1.2}] = O\left(n^{-1}\mathbb{E}\left[f_k^{-1}\|r_j - r_k\| |r_j - r_l| L_{njk} ||L_{njl}\| |K_{nij}|\right]\right)
= O\left(n^{-1}g^{-p}\mathbb{E}\left[f_k^{-1}\|r_j - r_k\| |r_j - r_l| L_{njk} ||L_{njl}\| |K_{nij}|\right]\right)
= O\left(n^{-1}g^{-p}\mathbb{E}\left[f_k^{-1}\|r_j - r_k\| |L_{njk}\| |L_{njl}| |Z_j| |K_{nij}|\right]\right)
= o\left(n^{-1}g^{-p}\right) \mathbb{E}\left[f_k^{-1}\|r_j - r_k\| |L_{njk}\| |K_{nij}|\right]
= o\left(n^{-1}g^{-p}\right).
\]

To prove that the term $I^*_{3,5.1.2} = o_p(nh^{p/2})$ it suffices to prove $\mathbb{E}[|I^*_{3,5.1.2}|] = o(nh^{p/2})$ and this latter rate is implied by the condition $h/g^2 = o(1)$. This additional condition on the bandwidths is not surprising as the bootstrapped statistic introduced “diagonal” terms as in Fan and Li (1996) which indeed require the condition $h/g^2 \to 0$.

Let us now consider a term in the decomposition of $D^*_5$ that involve bootstrap variables $\eta$, namely we investigate $I^*_2$. The arguments for the other terms are similar. Consider

\[
I^*_2 = \frac{1}{n^{(4)}} \sum_a \left( \eta_i \hat{u}_i - \eta_k \hat{u}_k \right) \left( \hat{r}_j - \hat{r}_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}
\]

\[
= \frac{1}{n^{(4)}} \sum_a \eta_i \hat{u}_i \left( r_j - r_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}
+ \frac{1}{n^{(4)}} \sum_a \eta_k \hat{u}_k \left( r_j - r_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}
- \frac{1}{n^{(4)}} \sum_a \eta_i \hat{u}_i \left( \hat{r}_j - r_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}
- \frac{1}{n^{(4)}} \sum_a \eta_k \hat{u}_k \left( \hat{r}_j - r_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}
+ \frac{1}{n^{(4)}} \sum_a \eta_k \hat{u}_k \left( \hat{r}_l - r_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}
= I^*_{2,1} + I^*_{2,2} - I^*_{2,3} - I^*_{2,4} + I^*_{2,5} + I^*_{2,6}.
\]

Next it suffices to use the fact that

\[
\hat{u}_i = u_i - \hat{f}_i^{-1} \sum_{i' \neq i} \eta_{i'j} L_{nj} + \hat{f}_i^{-1} \sum_{i' \neq i} (r_i - r_{i'}) L_{nij}.
\]

For instance, using this identity with $I^*_{2,1}$ we can write

\[
I^*_{2,1} = \frac{1}{n^{(4)}} \sum_a \eta_i u_i \left( r_j - r_l \right) L_{nik} L_{njl} K_{nij} \psi_{ij}.
\]
of order three with kernel $H$.

Handling one problem at a time, let us notice that $\forall j\in\{1,2,3\}$, the $V_{ij}^*$s are obtained by replacing the $Y_i$'s by the $Y_i^*$'s in the $V_{ij}$s. All these terms could be handled by arguments similar to the ones detailed above. The proof of Theorem 2 is now complete.
Appendix: Additional proofs

We here provide proofs of technical lemmas and additional details for the proofs in the manuscript. We define $Z_i = (Y_i, W_i, X_i)$, $\|\psi\|_\infty = \sup_{x \in \mathbb{R}^d} |\psi(x)|$, 

$$K_{nij} = |K_{nij}| = \frac{1}{h^p} \left| K \left( \frac{W_i - W_j}{h/\gamma} \right) \right|,$$

and 

$$L_{nij} = |L_{nij}| = \frac{1}{g^p} \left| L \left( \frac{W_i - W_j}{g} \right) \right|.$$

**Proof of Lemma 2.** 1. We have 

$$E[A_n] = \frac{4h^p}{(n-1)^2} \sum_{i=2}^{n} \sum_{j=1}^{n-1} E \left[ \sigma_i^2 \sigma_j^2 f_i f_j K_{nij}^2 \psi_{ij}^2 \right] = \frac{2n^2h^p}{n-1} E \left[ \sigma_i^2 \sigma_j^2 f_i f_j K_{nij}^2 \psi_{ij}^2 \right],$$

and 

$$\text{Var}[A_n] \leq \frac{64h^p \|\psi\|_\infty^4}{(n-1)^4} \sum_{i=3}^{n} \sum_{j=2}^{n-1} \sum_{j' = 1}^{n-1} E \left[ \sigma_i^4 \sigma_j^4 f_i^2 f_j^2 f_{ii}^2 f_{jj}^2 K_{nij}^2 K_{nij'}^2 \right] + \frac{32h^p \|\psi\|_\infty^4}{(n-1)^4} \sum_{i=3}^{n} \sum_{j=2}^{n-1} \sum_{j' = 1}^{n-1} E \left[ \sigma_i^4 \sigma_j^4 f_i^2 f_j^2 f_{ii}^2 f_{jj}^2 K_{nij}^2 K_{nij'}^2 \right] + \frac{16h^p \|\psi\|_\infty^4}{(n-1)^4} \sum_{i=2}^{n} \sum_{j=1}^{n-1} E \left[ \sigma_i^4 f_i^2 u_j^2 f_j^4 K_{nij}^4 \right] = O \left( n^{-1} \right) \left[ \sigma_i^4 \sigma_j^2 f_i^2 f_j^2 f_{ii}^2 f_{jj}^2 K_{nij} K_{nij} \right] + O \left( n^{-1} \right) \left[ \sigma_i^4 \sigma_j^2 f_i^2 f_j^2 f_{ii}^2 f_{jj}^2 K_{nij} K_{nij} \right] + O \left( n^{-1} \right) \left[ \sigma_i^4 f_i^2 u_j^2 f_j^4 K_{nij} \right] = O \left( n^{-1} \right) + O \left( n^{-2} h^{-p} \right).$$

Deduce that Var$[A_n] \to 0$, and hence remains to show that $E[A_n] \to \omega^2$. We have 

$$h^p \ E \left[ \sigma_i^2 f_i^2 \sigma_j^2 f_j^2 K_{nij}^2 \psi_{ij}^2 \right] = \mathbb{E} \left[ \int \varphi_{X_1}(t) \varphi_{X_1}(-t) \mathcal{F}[K^2](ht) \psi^2(X_1 - X_j) \ dt \right]$$

where $\varphi_x(t) = \mathcal{F}[\sigma^2(\cdot, x) f^2(\cdot) \pi(\cdot | x)](t)$. Let us note that 

$$\mathbb{E} \left[ \int |\varphi_{X_1}(t) \varphi_{X_1}(-t)\psi^2(X_1 - X_j) \ dt \right] \leq \|\psi\|_\infty \mathbb{E} \left[ \int |\varphi_x(t)|^2 \ dt \right] = \|\psi\|_\infty \mathbb{E} \left[ \sigma^4(W, X) f^4(W) \pi(W | X) \right],$$

by Plancherel Theorem. Moreover, $\mathcal{F}[K^2](ht)$ is bounded and converges point-wise to $\int K^2(s) ds$ as $h \to 0$. Then by Lebesgue’s dominated convergence theo-
rem,
\[ h^p \mathbb{E} [\sigma_i^2 f_i^2 \sigma_j^2 f_j^2 K_{nij}^2 \psi_{ij}^2] \rightarrow \mathbb{E} \left[ \int \varphi_{X_i}(t) \varphi_{X_j}(-t) \psi^2 (X_i - X_j) \, dt \right] \int K^2(s) \, ds = \omega^2, \]
by Parseval’s Theorem.

2. By elementary calculations,
\[
\mathbb{E} [B_n^2] = \frac{64h^{2p}}{(n-1)^4} \sum_{i=3}^{n} \sum_{j=2}^{n-1} \sum_{j'=2}^{n} \sum_{k=1}^{n-1-j-1} \sum_{k'=1}^{j-1} \mathbb{E} [\sigma_i^2 f_i^2 \sigma_j^2 f_j^2 \sigma_k^2 f_k^2 K_{nij} K_{nij'} K_{nik} K_{nik'} K_{nk'k}] \\
\leq \frac{64h^{2p} \|\psi\|_4^4}{(n-1)^4} \sum_{i=3}^{n} \sum_{j=2}^{n-1} \sum_{j'=2}^{n} \sum_{k=1}^{n-1-j-1} \sum_{k'=1}^{j-1} \mathbb{E} [\sigma_i^4 f_i^4 \sigma_j^2 f_j^2 \sigma_k^2 f_k^2 K_{nij} K_{nij'} K_{nik} K_{nik'} K_{nk'k}] \\
+ \frac{128h^{2p} \|\psi\|_4^4}{(n-1)^4} \sum_{i=3}^{n} \sum_{j=2}^{n-1} \sum_{j'=2}^{n} \sum_{k=1}^{n-1-j-1} \sum_{k'=1}^{j-1} \mathbb{E} [\sigma_i^2 f_i^2 \sigma_j^2 f_j^2 \sigma_k^2 f_k^2 K_{nij} K_{nij'} K_{nik} K_{nik'} K_{nk'k}] \\
= O(n^{-1}) \mathbb{E} [\sigma_i^4 f_i^4 \sigma_j^2 f_j^2 \sigma_k^2 f_k^2 K_{nij} K_{nik}] \\
+ O(h^p) \mathbb{E} [\sigma_i^2 f_i^2 \sigma_j^2 f_j^2 \sigma_k^2 f_k^2 K_{nij} K_{nik'} K_{nik}] \\
= O(n^{-1}) + O(h^p) = o(1).
\]

3. We have \( \forall \varepsilon > 0, \forall n \geq 1, \) and \( 1 < i \leq n, \)
\[
\mathbb{E} \left[ G_{n,i}^2 | (|G_{n,i}| > \varepsilon) \big| \mathcal{F}_{n,i-1} \right] \leq \mathbb{E}^{1/2} \left[ G_{n,i}^4 | \mathcal{F}_{n,i-1} \right] \mathbb{E}^{1/2} \left[ I (|G_{n,i}| > \varepsilon) \big| \mathcal{F}_{n,i-1} \right] \\
\leq \frac{\mathbb{E} \left[ G_{n,i}^4 | \mathcal{F}_{n,i-1} \right]}{\varepsilon^2}.
\]

Then
\[
\sum_{i=2}^{n} \mathbb{E} \left[ G_{n,i}^2 | (|G_{n,i}| > \varepsilon) \big| \mathcal{F}_{n,i-1} \right] \\
\leq \frac{1}{\varepsilon^2} \sum_{i=2}^{n} \mathbb{E} [G_{n,i}^4 | \mathcal{F}_{n,i-1}] \\
\leq \frac{1}{\varepsilon^2} \frac{16h^{2p}}{(n-1)^4} \sum_{i=2}^{n} \mathbb{E} \left[ u_i^4 f_i^4 | W_i, X_i \right] \left( \sum_{j=1}^{i-1} u_j K_{nij} \psi_{ij} \right)^4
\]
The desired result follows.

The following result, known as Bochner’s Lemma (see Theorem 1.1.1. of Bochner (1955)) will be repeatedly used in the following. We recall it for the sake of completeness.

**Lemma 5.** For any function \( l(\cdot) \in \mathcal{U}^p \) and any integrable kernel \( K(\cdot) \),

\[
\sup_{x \in \mathbb{R}^p} \left| \int (y) \frac{1}{h^p} K \left( \frac{x - y}{h} \right) dy - l(x) \right| \to 0.
\]

In the following we provide the proofs for rates for the remaining terms in the decomposition of \( I_n \), see Propositions 3 and 4. For this purpose, we use the following a decomposition for \( U - \)statistics that can be found in Lavergne and Vuong (2000): if \( U_n = (1/n^{(m)}) \sum_{a} H_n (Z_{i_1}, \ldots, Z_{i_m}) \), then

\[
\mathbb{E} \left[ U_n^2 \right] = \left( \frac{1}{n^{(m)}} \right)^2 \sum_{c=0}^{m} \frac{n^{(2m-c)}}{c!} \sum_{|\Delta_1| = c | \Delta_2|} \sum_{|\Delta_1| = c | \Delta_2|} I(\Delta_1, \Delta_2)
\]

\[
= \sum_{c=0}^{m} O(n^{-c}) \sum_{|\Delta_1| = c | \Delta_2|} I(\Delta_1, \Delta_2),
\]

where \( \sum_{|\Delta_1| = c | \Delta_2|} \) denotes summation over sets \( \Delta_1 \) and \( \Delta_1 \) of ordered positions of length \( c \),

\[
I(\Delta_1, \Delta_2) = \mathbb{E} \left[ H_n (Z_{i_1}, \ldots, Z_{i_m}) H_n (Z_{j_1}, \ldots, Z_{j_m}) \right]
\]

and the \( i \)'s position in \( \Delta_1 \) coincide with the \( j \)'s position in \( \Delta_2 \) and are pairwise distinct otherwise. Now, we will bound \( \mathbb{E}[U_n^2] \) using the \( \xi_c = \sum_{|\Delta_1| = c | \Delta_2|} I(\Delta_1, \Delta_2) \) and
the fact that by Cauchy’s inequality,

\[ I^2 (\Delta_1, \Delta_2) = \mathbb{E}^2 [\mathbb{E} [H_n (Z_i, \ldots, Z_m) \mid Z_c] \mathbb{E} [H_n (Z_{ij}, \ldots, Z_{jm}) \mid Z_c]] \]

\[ \leq \mathbb{E} [\mathbb{E}^2 [H_n (Z_i, \ldots, Z_m) \mid Z_i] \mathbb{E}^2 [H_n (Z_{ij}, \ldots, Z_{jm}) \mid Z_i]] \]

where \( Z_c \) denotes the common \( Z_i \)'s.

**Proof of Proposition 3.** After bounding the \( \psi_{ij}'s \) by \( \|\psi\|_\infty \) the arguments are very similar to those used in Lavergne and Vuong (2000). We prove only the first statement.

(i) \( I_{1,3} \) is a U-statistic with kernel \( H_n (Z_i, Z_j, Z_l) = u_i f_i u_l L_{njl} K_{nij} \psi_{ij} \). We need to bound the \( \xi_c, c = 0, 1, 2, 3 \).

1. \( \mathbb{E} [H_n] = 0 \), thus \( \xi_0 = 0 \).

2. \( \xi_1 = O(\delta_n^2) \). Indeed, \( \mathbb{E} [H_n \mid Z_i] = \delta_n u_i \mathbb{E} [d_i f_i L_{nij} K_{nij} \psi_{ij} \mid Z_i] \) and \( \mathbb{E} [H_n \mid Z_i] = 0 = \mathbb{E} [H_n \mid Z_j] \). Then

\[ \mathbb{E} [\mathbb{E}^2 [H_n \mid Z_i]] \leq \|\psi\|_\infty^2 \delta_n^2 \mathbb{E} \left[ u_i^2 \mathbb{E}^2 [d_i f_i L_{nij} K_{nij} \mid Z_i] \right] \]

\[ = O (\delta_n^2) \mathbb{E} \left[ u_i^2 \mathbb{E}^2 [L_{nij} d_j f_j^3 \mid Z_i] \right] = O (\delta_n^2) . \]

3. \( \xi_2 = O(g^{-p}) \). Indeed, we have

\[ \mathbb{E} [H_n \mid Z_i, Z_j] = u_i f_i K_{nij} \psi_{ij} \mathbb{E} [u_l L_{njl} \mid Z_j] = 0, \]

\[ \mathbb{E} [H_n \mid Z_i, Z_l] = u_i f_i u_l \mathbb{E} [L_{nij} K_{nij} \psi_{ij} \mid Z_i, Z_l], \]

\[ \mathbb{E} [H_n \mid Z_j, Z_l] = u_l L_{njl} \mathbb{E} [u_i f_i K_{nij} \psi_{ij} \mid Z_j] = \delta_n u_i L_{njl} \mathbb{E} [d_i f_i K_{nij} \psi_{ij} \mid Z_j]. \]

By successive applications of Lemma 5,

\[ \mathbb{E} \left[ \mathbb{E}^2 (H_n \mid Z_i, Z_l) \right] \leq \|\psi\|_\infty^2 \mathbb{E} \left[ u_i^2 f_i^2 u_l^2 \mathbb{E} [L_{njl} K_{nij} \mid Z_i, Z_l] \right] \times \mathbb{E} \left[ L_{njl} K_{nij} \mid Z_i, Z_l] \right] \]

\[ = O (g^{-p}) \mathbb{E} \left[ u_i^2 f_i^2 u_l^2 \mathbb{E} [L_{njl} K_{nij} \mid Z_i, Z_l] \right] \times \mathbb{E} \left[ K_{nij} \mid Z_i, Z_l] \right] \]

\[ = O (g^{-p}) \mathbb{E} \left[ u_i^2 f_i^3 u_l^2 L_{njl} K_{nij} \right] = O (g^{-p}), \]

\[ \mathbb{E} [\mathbb{E}^2 [H_n \mid Z_j, Z_l]] \leq \|\psi\|_\infty^2 \delta_n^2 \mathbb{E} \left[ u_i^2 L_{njl}^2 \mathbb{E}^2 [d_i f_i K_{nij} \mid Z_j] \right] \]

\[ \leq O (\delta_n^2) \mathbb{E} \left[ u_i^2 L_{njl}^2 d_j^2 f_j^4 \right] \]

\[ = O (\delta_n^2) O (g^{-p}) \mathbb{E} \left[ u_i^2 L_{njl} d_j^2 f_j^4 \right] = O (g^{-p}) . \]

4. \( \xi_3 = O(g^{-p}h^{-p}) \), as \( \mathbb{E} [H_n^2] \) equals

\[ \mathbb{E} \left[ u_i^2 u_l^2 f_i^2 L_{njl}^2 K_{nij}^2 \psi_{ij}^2 \right] = O (g^{-p}h^{-p}) \mathbb{E} \left[ u_i^2 u_l^2 f_i^2 L_{njl} K_{nij} \right] \]

\[ = O (g^{-p}h^{-p}) . \]

Collecting results, \( \mathbb{E} [(nh^{p/2} I_{1,3})^2] = O(\delta_n^2 nhp) + O(h^p/g^p) + O(n^{-1}g^{-p}) = o(1). \)

\[ \square \]
Proof of Proposition 4. As in Proposition 3, we only prove the first statement. We will use the following lemma, which is similar to Lemma 2 of Lavergne and Vuong (2000), and whose proof is then omitted.

Lemma 6. Let \( \Delta f_i^j = \hat{f}_i^j - f_i \). If \( f(\cdot) \in \mathcal{W}^p \) and \( ng^p \to \infty \),

\[
E \left[ \Delta^2 f_i^j \mid Z_i, Z_j, Z_{i'}, Z_{j'} \right] = o(1)
\]

and

\[
E \left[ \Delta^2 f_i^{j,1} \mid Z_i, Z_j, Z_{i'}, Z_{j'}, Z_{i''} \right] = o(1)
\]

uniformly in the indices.

(i) Let us denote \( \Delta f_i^j = \hat{f}_i^j - f_i \). We have

\[
I_{1,1} = (1/n^{(2)}) \sum u_i \Delta f_i^j u_j f_j K_{nij} \psi_{ij}
\]

so that

\[
E \left[ I_{1,1}^2 \right] = \left( \frac{1}{n^{(2)}} \right)^2 \left[ \sum u_i \Delta f_i^j u_j f_j K_{nij} \psi_{ij} \right] \times \left[ \sum u_i' \Delta f_i^{j'} u_j' f_j' K_{nij'} \psi_{ij'} \right]
\]  

(7)

where the first (respectively the second) sum is taken over all arrangements of different indices \( i \) and \( j \) (respectively different indices \( i' \) and \( j' \)). Let \( W \) denote the sample of \( W_i \), \( 1 \leq i \leq n \), and let \( \lambda_n = E(\Delta^2 f_i^j \mid Z_i, Z_j, Z_{i'}, Z_{j'}) \). By Lemma 6, \( \lambda_n = o(1) \) uniformly in the indices. By Equation (7), \( E[I_{1,1}^2] \) is equal to a normalized sum over four indices. This sum could split in three sums of the following types.

1. All indices are different, that is a sum of \( n^{(4)} \) terms. Each term in the sum can be bounded as follows:

\[
E \left[ u_i \Delta f_i^j u_j f_j K_{nij} \psi_{ij} u_i' \Delta f_i^{j'} u_j' f_j' K_{nij'} \psi_{ij'} \right] \leq ||\psi||^2 \delta_n^4 E \left[ \Delta f_i^j f_j \Delta f_i^{j'} f_j' E \left[ d_i d_j d_{i'} d_{j'} K_{nij} K_{nij'} \mid W \right] \right]
\]

\[
\leq ||\psi||^2 \delta_n^4 E \left[ f_j f_{j'} d_i d_{i'} d_j d_{j'} K_{nij} K_{nij'} \right] \times E \left[ \Delta f_i^j \Delta f_i^{j'} \mid Z_i, Z_j, Z_{i'}, Z_{j'} \right]
\]

\[
\leq O(\delta_n^4 \lambda_n) E \left[ f_j f_{j'} d_i d_{i'} d_j d_{j'} K_{nij} K_{nij'} \right] = O(\delta_n^4 \lambda_n).
\]

2. One index is common to \( \{i, j\} \) and \( \{i', j'\} \), that is a sum of \( 4n^{(3)} \) terms. For each of such terms we can write

\[
(i = i') \quad E \left[ u_i^2 \Delta f_i^j u_j f_j K_{nij} \psi_{ij} \Delta f_i^{j'} u_j' f_j' K_{nij'} \psi_{ij'} \right] \leq ||\psi||^2 \delta_n^4 E \left[ \Delta f_i^j f_j \Delta f_i^{j'} f_j' E \left[ u_i^2 d_j d_{j'} K_{nij} K_{nij'} \mid W \right] \right]
\]

\[
\leq O(\delta_n^4 \lambda_n) E \left[ f_j f_{j'} u_i^2 d_j d_{j'} K_{nij} K_{nij'} \right] = O(\delta_n^4 \lambda_n),
\]

and
(j' = j) \quad \mathbb{E} \left[ u_i \Delta f_i^1 u_j^2 f_j^2 K_{nij} \psi_{ij} u_i \Delta f_i^2 K_{n'i'j} \psi_{i'j} \right] \\
\quad \leq \left\| \psi \right\|_\infty^2 \delta_n^2 \mathbb{E} \left[ \Delta f_i^1 f_j^2 \Delta f_i^2 \mathbb{E} \left[ d_i u_i^2 d_j K_{nij} | \tilde{W} \right] \right] \\
\quad \leq O(\delta_n^2 \lambda_n) \mathbb{E} \left[ f_j^2 d_i u_i^2 d_j K_{nij} K_{n'i'j} \right] = O(\delta_n^2 \lambda_n), \\
(i' = j) \quad \mathbb{E} \left[ u_i \Delta f_i^1 u_j^2 f_j K_{nij} \psi_{ij} \Delta f_j^1 u_j^2 f_j K_{nij} \psi_{ij} \right] \\
\quad \leq \left\| \psi \right\|_\infty^2 \delta_n^2 \mathbb{E} \left[ \Delta f_i^1 f_j^2 \Delta f_j^1 f_j K_{nij} K_{nij} | \tilde{W} \right] \\
\quad \leq O(\delta_n^2 \lambda_n) \mathbb{E} \left[ f_j f_j, d_i u_j^2 d_j K_{nij} K_{nij} \right] = O(\delta_n^2 \lambda_n).

The case j' = i is similar to i' = j.

3. Two indices in common to \( i, j \) and \( i', j' \), that is a sum of \( 2n^2 \) terms. For each term in the sum we can write

\[ \mathbb{E} \left[ u_i^2 u_j^2 \left( \Delta f_i^1 \right)^2 f_j^2 K_{nij}^2 \psi_{ij}^2 \right] = O(\lambda n^{-p}) \]

and

\[ \mathbb{E} \left[ u_i^2 u_j^2 \Delta f_i^1 \Delta f_j^1 f_i f_j K_{nij}^2 \psi_{ij}^2 \right] = O(\lambda n^{-p}). \]

Therefore, \( \mathbb{E}[(nh^p/2I_{1,1})^2] = \delta_n^4 n^2 h^p O(\lambda n) + \delta_n^2 n h^p O(\lambda n) = O(\lambda n). \)

The result then follows from Lemma 6.

**Proof of Lemma 3.** We only prove the result for \( \Delta \hat{r}_i \hat{f}_i \), as the reasoning is similar for \( \Delta \hat{f}_i \). We have

\[ \Delta \hat{r}_i \hat{f}_i = \frac{1}{(n-1)g^p} \sum_{k \neq i} \{ Y_k L \left( (W_i - W_k)g^{-1} \right) - \mathbb{E} \left[ Y L \left( (W_i - W)g^{-1} \right) \right] \} \]

\[ + \mathbb{E} \left[ r(W)g^{-p} L \left( (W_i - W)g^{-1} \right) - r(W) \right] f(W) \]

\[ = \Delta_{1i} + \Delta_{2i}. \]

The uniform continuity of \( r(\cdot)f(\cdot) \) implies \( \sup_i |\Delta_{2i}| = o_p(1) \) by Lemma 5. For \( \sup_i |\Delta_{1i}| \), we use empirical process tools. Let us introduce some notation. Let \( \mathcal{G} \) be a class of functions of the observations with envelope function \( G \) and let

\[ J(\delta, \mathcal{G}, L^2) = \sup_Q \int_0^\delta \sqrt{1 + \ln N(\varepsilon, \mathcal{G}, L^2(Q))} \, d\varepsilon, \quad 0 < \delta \leq 1, \]

denote the uniform entropy integral, where the supremum is taken over all finitely discrete probability distributions \( Q \) on the space of the observations, and \( ||G||_2 \) denotes the norm of \( G \) in \( L^2(Q) \). Let \( Z_1, \ldots, Z_n \) be a sample of independent observations and let

\[ \mathbb{E}_{n} g = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \gamma(Z_i), \quad \gamma \in \mathcal{G} \]

be the empirical process indexed by \( \mathcal{G} \). If the covering number \( N(\varepsilon, \mathcal{G}, L^2(Q)) \) is of polynomial order in \( 1/\varepsilon \), there exists a constant \( c > 0 \) such that \( J(\delta, \mathcal{G}, L^2) \leq c\delta \sqrt{\ln(1/\delta)} \) for \( 0 < \delta < 1/2 \). Now if \( \mathbb{E}_{n} g^2 < \delta^2 EG^2 \) for every \( \gamma \) and some
0 < \delta < 1$, and \( \mathbb{E} G^2(4v-2)/(v-1) < \infty \) for some \( v > 1 \), under mild additional measurability conditions, Theorem 3.1 of van der Vaart and Wellner (2011) implies

\[
\sup_{\gamma} |G_n\gamma| = J(\delta, G, L^2) \left( 1 + \frac{J(\delta^{1/v}, G, L^2)}{\delta^2 \sqrt{n}} \frac{\|G\|^{2-1/v}}{(4v-2)/(v-1)} \right)^{v/(2v-1)} \|G\|_2 O_p(1),
\]

(8)

where \( \|G\|_2^2 = \mathbb{E} G^2 \) and the \( O_p(1) \) term is independent of \( n \). Note that the family \( \mathcal{G} \) could change with \( n \), as soon as the envelope is the same for all \( n \). We apply this result to the family of functions \( \mathcal{G} = \{ YL((W-w)/g) : w \in \mathbb{R}^p \} \) for a sequence \( g \) that converges to zero and the envelope \( G(Y, W) = Y \) sup \( w \in \mathbb{R}^p \|L(w)\| \). Its entropy number is of polynomial order in \( 1/\varepsilon \), independently of \( n \), as \( L(\cdot) \) is of bounded variation, see for instance van der Vaart and Wellner (1996). Now for any \( \gamma \in \mathcal{G}, \mathbb{E}\gamma^2(Y, W) \leq C g^p \mathbb{E} G^2(Y, W), \) for some constant \( C \). Let \( \delta = g^{p/2} \), so that \( \mathbb{E}\gamma^2(Y, W) \leq C^2 \delta^2 \mathbb{E} G^2(Y, W), \) for some constant \( C^2 \) and \( v = 3/2 \), which corresponds to \( \mathbb{E} G^8 < \infty \) that is guaranteed by our assumptions. The bound in (8) thus yields

\[
\sup_{\gamma} \left| \frac{1}{g^p \sqrt{n}} G_n\gamma \right| = \frac{\ln^{1/2}(n)}{\sqrt{n} g^p} \left( 1 + n^{-1/2} g^{-2p/3} \ln^{1/2}(n) \right)^{3/4} O_p(1),
\]

where the \( O_p(1) \) term is independent of \( n \). Since \( n g^{4p/3} / \ln n \to \infty \), the expected result follows.

**Proof of Lemma 4.** We have

\[
\hat{u}_i^* \hat{f}_i = \frac{1}{n-1} \sum_{k \neq i} (Y_i^* - Y_k^*) L_{niki}
= u_i^* \hat{f}_i - \frac{1}{n-1} \sum_{k \neq i} u_k^* L_{niki} + \frac{1}{n-1} \sum_{k \neq i} (\hat{r}_i - \hat{r}_k) L_{niki},
\]

where

\[
\frac{1}{n-1} \sum_{k \neq i} (\hat{r}_i - \hat{r}_k) L_{niki} = \frac{1}{n-1} \sum_{k \neq i} (r_i - r_k) L_{niki} + (\hat{r}_i - r_i) \hat{f}_i
- \frac{1}{(n-1)^2} \hat{f}_i \sum_{k \neq i} \sum_{k' \neq k} (r_{k'} - r_k) L_{niki}^k L_{niki}^k
- \frac{1}{(n-1)^2} \hat{f}_i \sum_{k \neq i} \sum_{k' \neq k} u_{k'} L_{niki}^k L_{niki}^k.
\]

By Lemma 3 and the fact that \( f(\cdot) \) is bounded away from zero, deduce that \( \sup_i |\hat{r}_i - r_i| = o_p(1) \). From this and applying several times the arguments in the proof of Lemma 3 we obtain

\[
\frac{1}{n-1} \sum_{k \neq i} (\hat{r}_i - \hat{r}_k) L_{niki} = o_p(1).
\]
On the other hand,
\[
\left| \frac{1}{n-1} \sum_{k \neq i} u_k^* L_{nik} \right| \leq \left| \frac{1}{n-1} \sum_{k \neq i} \eta_k u_k L_{nik} \right| + \sup_j |\hat{r}_j - r_j| \frac{1}{n-1} \sum_{k \neq i} |\eta_k| L_{nik} = o_p (1), \tag{1}
\]
where we used again the arguments for $\Delta_{1i}$ in the proof of Lemma 3 (here with $\eta_k u_k$ and $|\eta_k|$ in the place of $Y_k$) to derive the last rate.
