Abstract The physical properties of static analytic solutions which describe black brane geometries are discussed. In particular we study the similarities and differences of analytic black brane/string solutions in the Einstein and Jordan frames. The comparison is made between vacuum power law $f(R)$ gravity solutions and their conformal equivalents in the Einstein frame. In our analysis we examine how the geometrical and physical properties of these analytic axisymmetric solutions—such as singularities, the temperature and the entropy—are affected as we pass from one frame to the other.

1 Introduction

The need to determine a mechanism which provides a theoretical prediction on the recent observable phenomena in cosmology, such as the late-time acceleration phase of the universe [1–5], has led cosmologists to introduce (alternative/modified) gravitational theories which are defined in the Jordan frame [6] instead of the Einstein frame of General Relativity [7–10].

One of the first proposed theories in the literature, which is formulated in the Jordan frame, is the Brand–Dicke gravitational theory [11]. More specifically, Brans–Dicke theory is based on Mach’s principle [12]; the gravitational field is described by the metric tensor and a scalar field nonminimally coupled to gravity. Moreover, the gravitational constant $G$ depends on the value of nonminimally scalar field, and on a constant $\omega_{BD}$ which is called Brans–Dicke parameter. Hence, $G$ is actually an effective function rather a constant, for a discussion see also [13,14]. In what regards the limits of parameter $\omega_{BD}$, while someone expects General Relativity to be recovered when $\omega_{BD}$ reaches infinity, it was actually demonstrated that this is not true. This implies that the two theories are fundamentally different [15]. On the other hand, in the limit where the Brans–Dicke parameter vanishes, i.e. $\omega_{BD} = 0$, the theory is equivalent with that of a massive Dilaton theory [16], as it has been shown by O’Hanlon\textsuperscript{1} [17]. Moreover, Brans–Dicke theory provides a radiation epoch in the evolution of the universe as also a de Sitter phase [18,19], which can be related with the late-time acceleration phase of the universe [20]. It has also been proposed that the Brans–Dicke parameter should not be a constant but rather depend on the nonminimally coupled field. This led to a zoology of theories known as scalar–tensor theories [21]. For other generalizations of Brans–Dicke action see for instance [22–31] and references therein.

Scalar–tensor theories are conformally equivalent to General Relativity [21,32–34]. However, the latter is just a mathematical equivalence between the Jordan and the Einstein frame on the solution space of the field equations. By conformal equivalency we mean, point transformations in which the two geometries, i.e. the two metrics in the Jordan frame and in the Einstein frame, are related with a conformal factor. What is more, the conformal equivalency of scalar–tensor theories with General Relativity is true only in the case where there are not any specific conditions imposed from an extra matter source, that is except of the scalar field; we refer the reader to a recent discussion in [35]. In particular, if there exists an additional matter source which is minimally coupled to the scalar field in one of the frames, then under the conformal transformation there will be an interaction between the matter source and the scalar field, which means that the extra matter source will not be minimally coupled to the latter. Moreover, while the energy conditions for the scalar field

\textsuperscript{1} The Brans–Dicke action with $\omega_{BD} = 0$ is also known as O’Hanlon gravity.

\textsuperscript{b}e-mail: alexgiacomini@uach.cl
\textsuperscript{c}e-mail: anpaliat@phys.uoa.gr
are satisfied in the Einstein frame, they can be violated in the Jordan frame [36, 37]. From cosmological studies, it has been found that while a theory can provide an acceleration phase in one frame it may not be able to do so in the other. From this it is clear the conformal equivalence transformation between the two frames does not necessarily mean physical equivalence; see also the discussions in [34, 38–46] and references therein. The study of the physical properties between the Jordan and the Einstein frame has been extended to astrophysical objects, such as black-holes [47–51] or to even more exotic configurations like the wormholes [52–54] and the black branes or strings [55, 56].

There is a family of higher-order theories which can also be described in the form of second order scalar–tensor theories [57–63]. In these cases new degrees of freedom, which are introduced by the higher-order derivatives, can be attributed to nonminimally scalar fields. The standard method to do so is with the use of Lagrange multipliers [64–68]. Consequently, higher-order theories can provide the mechanics for the scalar field description, an approach which has been applied to describe inflation [69–72].

One of the simplest higher-order theories which has drawn the attention of the scientific society the last years is $f(R)$-gravity. More specifically, it is a fourth-order theory in which the Einstein–Hilbert action is modified so as to become a general function, $f$, of the Ricci scalar, $R$, of the underlying geometry [73]. Its equivalent description as a scalar–tensor theory is in the form of Brans–Dicke theory with parameter $\omega_{BD}$ zero. That is, $f(R)$-gravity is equivalent with the so-called O’Hanlon theory [57]. In the family of $f(R)$-gravity there belongs one of the most popular inflationary models, the Starobinsky model for inflation [69]. There are other cosmological tests that have shown that the theory can also describe the late-time acceleration phase of the universe [74–76]. Some astrophysical applications of $f(R)$-gravity can be found in [77–86] and a black hole topology theorem has been presented lately in [87].

Recently, in the context of $f(R)$-gravity, a new family of analytical solutions in a four-dimensional static spacetime was found in [88]. That new family of solutions can support black branes or strings in vacuum when axisymmetry is introduced in the line element. These solutions are not asymptotically maximally symmetric. The study of the thermodynamic parameters for the black brane/string solution extracted in the context of the power-law theory $f(R) = R^k$, has shown that the entropy function has positive values only when $0 < k < \frac{1}{2}$ or the power $k$ is a negative, even integer.

The purpose of this work is to study the effects of the conformal transformation between the Jordan and the Einstein frames for the black brane solution determined in [88]. Black branes/string solutions can be easily constructed in Einstein’s gravity and in some modified theories of gravity by trivially embedding black hole solutions in higher dimensions [89–95]. However, the results of [88] are not based on this technique and the resulting spacetime is not constructed by the embedding of a lower dimensional solution in four dimensions. In this work we use the results obtained in [88] so as to construct the analytical solution of General Relativity with a minimally coupled scalar field for a four-dimensional static axisymmetric spacetime. Furthermore, we shall study the differences of the specific solutions; an important analysis in order the investigate the physical (in-)equivalence of the two frames for static axisymmetric solutions.

The plan of the paper is as follows: in Sect. 2 we briefly discuss the conformal transformation which connects the Jordan and the Einstein theory. In Sect. 3 we present the gravitational field equations that correspond to the system under study. The analytical solution which was determined in [88] is discussed in Sect. 4. The black brane solution in the Einstein frame is determined in Sect. 5. The temperature and the entropy for the solution in the Einstein frame are calculated in Sect. 6. Finally, in Sect. 7 we draw our conclusions.

### 2 Conformal transformations

By definition conformal transformations generalize the concept of isometries; in particular, conformal transformations are angle-preserving transformations compared to the isometries which preserve both the length and the angles between lines. Two metric tensors are conformally related when there exists a scalar $\mathcal{N}(x)$ such that

$$\tilde{g}_{\mu\nu}(x) = N^2(x) g_{\mu\nu}(x)$$  \hspace{1cm} (1)

while the Ricci scalar $\tilde{R}(\tilde{g})$ of $\tilde{g}_{\mu\nu}$ is given in terms of the Ricci scalar $R(g)$ for the metric $g_{\mu\nu}$ and $\mathcal{N}(x)$ as [96]

$$\tilde{R}(\tilde{g}) = N^{-2} R(g) - 6 N^{-3} g_{\mu\nu} N;\mu;\nu,$$  \hspace{1cm} (2)

whenever $g_{\mu\nu}$ denotes a four-dimensional space, that is, $\dim g_{\mu\nu} = 4$. The covariant derivatives on the right hand side of (2) are defined with respect to the metric $g_{\mu\nu}$. Two Action integrals, or more specifically Lagrangians, are called conformally equivalent if the solution of the Euler-Lagrange equations survives under the action of the conformal transformation [35].

Let us now consider the scalar–tensor theory in the four-dimensional space with metric $\tilde{g}_{\mu\nu}$, that is given by

$$S(\varphi, \tilde{g}) = \int d^4x \sqrt{-\tilde{g}} \left( F(\varphi) \tilde{R}(\tilde{g}) - \frac{\alpha}{2} \tilde{g}^{\mu\nu} \tilde{\varphi}_{,\mu} \tilde{\varphi}_{,\nu} - V(\varphi) \right),$$  \hspace{1cm} (3)

where $\varphi$ denotes the nonminimally coupled scalar field and $V(\varphi)$ is the potential which drives the dynamics for this
field. The parameter $\alpha$ is the analogue of the Brans–Dicke parameter, $\alpha = \omega_{BD}$, when the function $F(\varphi)$ is quadratic, that is,$^2$ $F(\varphi) \simeq \varphi^2$. On the other hand, when $\alpha = 0$, the Action integral (3) describes the O’Hanlon gravity which is equivalent to the $f(R)$-gravity.

For the conformally related metric $g_{\mu\nu}$, the Action Integral (3) with the use of expression (2) becomes

$$S(\varphi, g) = \int d^4x \sqrt{-g} \left( F(\varphi) N^2 R(g) - \frac{\alpha}{2} N^2 g^{\mu\nu} \varphi_{,\mu} \varphi_{,\nu} 
- N^4 V(\varphi) - 6 F(\varphi) N^4 g^{\mu\nu} N_{,\mu\nu} \right).$$

(4)

while integration by parts simplify the latter to $[97]$

$$S(\varphi, g) = \int d^4x \sqrt{-g} \left( F(\varphi) N^2 R(g) - \frac{\alpha}{2} N^2 g^{\mu\nu} \varphi_{,\mu} \varphi_{,\nu} 
- N^4 V(\varphi) - 6 F(\varphi) g^{\mu\nu} N_{,\mu\nu} \right).$$

(5)

It is straightforward to see that scalar $N(x)$ does not provide any new degrees of freedom and actually is a degenerate function. Thus, without loss of generality, we can remove it from the Action integral by choosing $N = N(\varphi(x))$. In such a case, the Action Integral (5) is written as

$$S(\varphi, g) = \int d^4x \sqrt{-g} \left( \bar{F}(\varphi) R(g) 
- \frac{\alpha}{2} H(\varphi) g^{\mu\nu} \varphi_{,\mu} \varphi_{,\nu} - \hat{V}(\varphi) \right).$$

(6)

where

$$H(\varphi) = \left( N^2 + \frac{12}{\alpha} (N F_{,\varphi} N_{,\varphi} + F(\varphi) (N^2)^2) \right),$$

$$\bar{F}(\varphi) = F(\varphi) N^2,$$

and $\hat{V}(\varphi) = N^4 V(\varphi)$. (7)

We define the new field $\phi(x)$ such that $d\phi = \sqrt{H(\varphi)} d\varphi$, then the Action integral (6) is simplified as

$$S(\phi, R) = \int d^4x \sqrt{-g} \left( \bar{F}(\phi) R(g) - \frac{\alpha}{2} g^{\mu\nu} \varphi_{,\mu} \varphi_{,\nu} - \hat{V}(\phi) \right).$$

(8)

Recall that the latter transformation is a coordinate transformation and does not affect the dynamics of the system.

The Action Integral (8) still describes a scalar–tensor theory in the Jordan frame. However, when $\bar{F}(\varphi) = const.$, that is when $F(\varphi) N(\varphi)^2 = const.$, the Action Integral takes the form of the one of General Relativity with a minimally coupled scalar field, i.e.

$$S(\phi, R) = \int d^4x \sqrt{-g} \left( R(g) - \frac{1}{2} g^{\mu\nu} \varphi_{,\mu} \varphi_{,\nu} - \hat{V}(\phi) \right).$$

(9)

where without loss of generality we have chosen $\alpha = 1$.

Indeed, the two Action integrals (3) and (9) are conformally related but it is important to mention that $g$ and $\tilde{g}$ are in principle two different metrics. In the sense that there does not necessarily exist a space-time diffeomorphism linking the two space-times. Hence, while the above transformation can be used to map solutions between the two frames, one should be very careful about the possible physical (in-)equivalence of the two theories.

At this point, just for the convenience of the reader, we briefly want to demonstrate the equivalence of $f(R)$-gravity with Brans–Dicke theory with $\omega_{BD} = 0$, that is the O’Hanlon theory. The Action Integral in $f(R)$-gravity, for the line element $\tilde{g}_{\mu\nu}$, is given as follows

$$S_{f(R)} = \int d^4x \sqrt{-\tilde{g}} f\left( \tilde{R} \left( \tilde{g} \right) \right),$$

(10)

with the field equations resulting from the variation with respect to the metric being

$$f_{,\tilde{R}_{\mu\nu}} - \frac{1}{2} \tilde{g}_{\mu\nu} \left( \nabla_{\mu} \nabla_{\nu} - \tilde{g}_{\sigma\nu} \nabla_{\sigma} \nabla^{\sigma} \right) f_{,\tilde{R}} = 0.$$ (11)

Without loss of generality we introduce the Lagrange multiplier $\lambda$, such that

$$S_{f(R)} = \int d^4x \sqrt{-\tilde{g}} \left( f\left( \tilde{R} \left( \tilde{g} \right) \right) + \lambda \left( \tilde{R} \left( \tilde{g} \right) - \tilde{R}_{ex} \right) \right).$$

(12)

where $\tilde{R}_{ex}$ denotes the expansion of the Ricci scalar in terms of the functions of the metric $\tilde{g}_{\mu\nu}$.

Variation with respect to the Ricci scalar $\tilde{R}$ at the Action Integral (12) gives the Euler–Lagrange equation $[57]$

$$\delta S_{f(R)} \Big|_{\tilde{R}} \tilde{g}_{\mu\nu} = 0,$$

or $\lambda = - f_{,\tilde{R}} \left( \tilde{R} \right)$, which defines the Lagrange multiplier $\lambda$. By substituting the latter in (12) it follows that $[63]$

$$S_{f(R)} = \int d^4x \sqrt{-\tilde{g}} \left( f_{,\tilde{R}} \left( \tilde{R} \right) \tilde{R}_{ex} \left( \tilde{g} \right) + \left( f\left( \tilde{R} \right) - f_{,\tilde{R}} \tilde{R} \right) \right)$$

and by defining the new scalar $\varphi = f_{,\tilde{R}} \left( \tilde{R} \right)$ we obtain the scalar–tensor theory

$$S_{f(R),\varphi} = \int d^4x \sqrt{-\tilde{g}} \left( \varphi \tilde{R}_{ex} \left( \tilde{g} \right) - V_f(\varphi) \right),$$

(14)

in which $V_f(\varphi) = (\varphi \tilde{R} (\varphi) - f \left( \tilde{R} (\varphi) \right))$. This latter action $^3$ describes the Brans–Dicke theory with $\omega_{BD} = 0$. The corresponding equations for the gravitational and scalar field are

$^2$ When $F(\varphi) \simeq \varphi^2$, then under the reparametrizations $\varphi = \sqrt{\overline{g}}$ for the scalar-field, the Action integral (3) is written in the usual Brans–Dicke form $[11]$.

$^3$ Recall that by definition $\tilde{R}_{ex} \equiv \tilde{R} \left( \tilde{g} \right)$.
\[ \varphi \left( \bar{R}_{\mu \nu} - \frac{1}{2} g_{\mu \nu} \bar{R} \right) + \left( \bar{g}_{\mu \nu} \nabla_\sigma \nabla^\sigma \varphi - \nabla_\mu \nabla_\nu \varphi \right) \]

\[ = \frac{1}{2} \bar{g}_{\mu \nu} V(\varphi) = 0 \]  

(15a)

\[ \bar{R} (\bar{g}) - V' (\varphi) = 0 \]  

(15b)

respectively. The latter set of equations is equivalent with the field equations (11). It is also true that \( f (R) \)-gravity defined in the Jordan frame is conformally equivalent to General Relativity induced by a minimally coupled scalar field. The conformal transformation which relates the Action Integrals (9), (14) is [57]

\[ g_{\mu \nu} = \varphi \bar{g}_{\mu \nu}, \quad \varphi = \sqrt{3} \ln \varphi. \]  

(16)

In the following section, we proceed with the derivation of the field equations for the static axisymmetric spacetime in the Einstein and Jordan frames, in particular that of \( f (R) \)-gravity. Moreover, we assume that there is not any extra matter source in the gravitational system except of the scalar field.

### 3 Field equations in static axisymmetric spacetime

Consider the four-dimensional static axisymmetric spacetime with line element

\[ d\bar{s}^2 = -a(\rho)^2 dt^2 + n(\rho)^2 dr^2 + b(\rho)^2 \left( dy^2 + dz^2 \right), \]  

(17)

which in general admits a four dimensional Killing algebra, consisted by the vector fields \( \{ \partial_t, \partial_\rho, \partial_\theta, \partial_\phi \} \).

In \( f (R) \)-gravity, the gravitational field equations (11) for metric (17) are equivalent to those produced by the variation, with respect to the variables \( \{ N (\rho), a (\rho), b (\rho), R (\rho) \} \), of the Lagrangian function

\[ \mathcal{L}_{f(R)} = \frac{2}{n} \left[ f, R \left( ab^2 + 2b a' b' \right) + f, R R \left( b^2 a' R' + 2a b b' R' \right) \right] \\
+ n a b^2 (f - R f, R), \]  

(18)

where the prime denotes a total derivative with respect to the variable \( r \), that is \( x' (r) = \frac{dx (r)}{dr} \).

On the other hand, in the scalar–tensor equivalent description, Lagrangian (18) takes the equivalent form

\[ \mathcal{L}_\varphi = \frac{2}{n} \left[ \varphi \left( ab^2 + 2b a' b' \right) + \left( b^2 a' \varphi' + 2a b b' \varphi' \right) \right] \\
- n a b^2 V (\varphi), \]  

(19)

while the corresponding Euler–Lagrange equations yield

\[ \frac{2}{n^2} \left[ \varphi \left( ab^2 + 2b a' b' \right) + \left( b^2 a' \varphi' + 2a b b' \varphi' \right) \right] \\
+ a b^2 V (\varphi) = 0, \]  

(20)

\[ 6a'' = \frac{2a}{b^2} b^2 + \frac{6}{n} a' n' - an^2 V_\varphi - \frac{4}{\varphi} a' \varphi' \\
+ \frac{4b'}{b \varphi} (a \varphi' - 2a' \varphi), \]  

(21)

\[ 6b'' = - \left( \frac{4}{b} b'^2 - bn^2 V_\varphi \right) + 2b' \left( \frac{3n'}{n} - \frac{\varphi'}{\varphi} \right) \\
+ \frac{2}{a \varphi} (b \varphi' - b' \varphi'), \]  

(22)

\[ 6\varphi'' = n^2 \left( 2b V_\varphi - 3 V (\varphi) \right) + 6n' \varphi' \\
+ \frac{2b' \left( 2a' n + ab' \right) - 4b (a b' + 2a b') \varphi'}{ab^2}, \]  

(23)

It can be straightforwardly verified that the above system is also equivalent to field Eq. (15) under the ansatz (17) for the line element. Consequently, Eqs. (20)–(23) are equivalent to the nonzero components for the field Eq. (11).

The conformal transformation (16) reads

\[ a (r) \rightarrow \varphi (r)^{-\frac{1}{2}} A (r), \quad b (r) \rightarrow \varphi (r)^{-\frac{1}{2}} A (r) \]

\[ n (r) \rightarrow \varphi (r)^{-\frac{1}{2}} N (r), \quad \varphi \rightarrow e^{-\frac{2}{\sqrt{3}} \phi} \]  

(24)

and under its use the field Eqs. (20)–(23) become

\[ \frac{1}{N^2} \left( 2A B'^2 + 4BA' B' - \frac{1}{2} AB^2 \varphi^2 \right) \\
+ AB^2 N \dot{\varphi} (\phi), \]  

(25)

\[ 8A'' = 8A' \left( \frac{N'}{N} - \frac{B'}{B} \right) + 4 \frac{A}{B^2} \varphi^2 - A \varphi^2 \\
- 2AN^2 \ddot{\varphi} (\phi), \]  

(26)

\[ 8B'' = - \frac{4}{B} B'^2 + \frac{8}{N} N' B' - B \varphi^2 \\
- 2BN^2 \ddot{\varphi} (\phi), \]  

(27)

and

\[ \varphi'' = - \left( \frac{A'}{A} + 2 \frac{B'}{B} \right) \varphi' + \frac{N'}{N} \varphi' + N^2 \ddot{\varphi}, \]  

(28)

in which \( \ddot{\varphi} (\phi) = e^{-\frac{2}{\sqrt{3}} \phi} V (\phi) \). Finally, under the transformation (24) the line element (17) can be written as \( d\bar{s}^2 = \varphi^{-1} d\bar{s}^2 \), where the new line element \( d\bar{s}^2 \) is now

\[ d\bar{s}^2 = -A(r)^2 dt^2 + n(r)^2 dr^2 + B(r)^2 \left( dy^2 + dz^2 \right). \]  

(29)

The set of Eqs. (25)–(28) describe the Einstein field equations with a minimally coupled scalar field, i.e. those generated from Action Integral (9), but for the line element (29), which is different from that of (17). Although the solutions of the conformal equivalent theories commute thought the conformal transformation (24), the physical and geometrical properties of the solutions can be extremely different due fact
that a conformal transformation cannot in general correspond to a diffeomorphism linking the two line elements.

4 Black branes in the Jordan frame

In this section, we briefly discuss the analytical solution for the gravitational field Eqs. (20)–(23) of f (R)-gravity which was derived recently in [88], and can describe four-dimensional black branes (or strings depending on the topology on which one endows the two dimensional surface). It was found in [88] that the line elements

\[ d\tilde{s}^2 = -r^2 \left( \frac{r^{\frac{4k-4}{m}}}{m} - 1 \right) dt^2 + r^2 \left( dy^2 + dz^2 \right), \quad \text{for } 1 < k < \frac{5}{4} \]  

(30)

and

\[ d\tilde{s}^2 = -r^2 \left( \frac{r^{\frac{4k}{m}}}{m} - 1 \right) dt^2 + r^2 \left( dy^2 + dz^2 \right), \quad \text{for } k < 1 \text{ or } k > \frac{5}{4}, \quad k \neq \frac{1}{2}. \]  

(31)

solve field Eq. (11) for a power-law f (R) = R^k theory, with k ≠ 0, 1, 4/5, 7/4. Given the form of the transformation that maps f (R)-gravity to the O’Hanlon theory we expect that the corresponding potential \( V_f \) also has a power law form. Specifically, we can see that the aforementioned potential is

\[ V_f (\varphi) = \pm \frac{6(4k - 5)}{2k - 1} \varphi^{\frac{k}{2k-1}}. \]  

(32)

and the corresponding scalar field is given by

\[ \varphi (r) = r^{\frac{2(k-2)}{2k-1}}. \]  

(33)

Expressions (32) and (33) satisfy the field equations (15) for line element (30) when we have the plus sign in (32). On the contrary, when we consider line element (31), we need to take into account the minus sign in potential (32).

The gravitational properties of the solutions in f (R)-gravity and the O’Hanlon theory are identical since they refer to the same metrics. For these two line elements the Ricci scalar and the Kretschmann scalar are derived to be

\[ R = \pm \frac{6k(4k - 5)r^{\frac{2(k-2)}{2k-1}}}{(k-1)(2k-1)}, \]  

(34)

and

\[ K = \frac{4}{(1 - 2k)^2(k - 1)^2 m^2} \left[ \left( 56k^4 - 264k^3 + 468k^2 - 370k + 11 \right) r - \left( 2k - 1 \right)(k - 1) \right] \]  

\[ -2m(k - 2)^2(2k - 1) r \]  

\[ + 3m^2 \left( 8k^4 - 20k^3 + 13k^2 - 2k + 2 \right) r^{\frac{4(k-2)}{2k-1}} \]. \]  

(35)

From the latter expressions it is clear that the spacetimes admit curvature singularity at \( r = 0 \), when \( k < 1/2 \) and \( 1 < k \leq 2 \). Moreover, it is straightforward to observe that a coordinate singularity exists at \( r = r_h = m^{\frac{1-k}{4k-5}} \), when \( m > 0 \) [88]. It is for these values of the parameters that we can consider that the space-time describes a black brane or a black string (if in this latter case we consider x and y as periodic variables). While the resulting spacetime is asymptotically Ricci flat, we can see that the curvature tensor \( R_{\mu\lambda\nu\sigma} \) does not tend to zero as \( r \) reaches infinity, which means that the spacetime cannot be asymptotically deformed to a maximally symmetric space. For a discussion on this kind of topological black holes (especially for a toroidal case two-surface) we refer the reader to [98].

In this context we can also study the type of an effective fluid corresponds two the line elements (30) and (31). By considering the anisotropic energy-momentum tensor \( T^{(0)}_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R \) generated by these geometries we may derive the energy density to be

\[ \rho_f (r) = \pm \frac{r^{\frac{2(k-2)}{2k-1}}}{m (2k - 1) (k - 1)} \left( \frac{56k^4 - 40k^3 + 13k^2 - 2k + 2}{2k^3 - 3k^2 + 7k - 7} \right), \]  

(36)

where the plus sign corresponds to metric (30) and the minus to (31) (together with the appropriate range of values for \( k \)). For the case where \( 1 < k < \frac{5}{4} \) we can see that \( \rho_f \) is positive as long as \( r > A_k r_h \), where

\[ A_k = \left( \frac{2k^2 - 7k + 6}{-6k^2 + 7k + 1} \right)^{\frac{k-1}{4k-5}}. \]  

(37)

The multiplicative constant \( A_k \) in front of the horizon radius \( r_h \) assumes values in the segment \((1, e)\) as \( k \) varies from 1 to \( \frac{5}{4} \). In the other range for \( k \) corresponding to solution (31)
the situation is more complicated. In order to have a positive energy density (36) one of the following conditions has to be met:

- \( \frac{1}{2} < k < 1 \), with \( r < A_k r_h \)
- \( \frac{1}{12} \left( 7 - \sqrt{73} \right) < k < \frac{1}{2} \) or \( \frac{5}{4} < k < \frac{1}{12} \left( \sqrt{73} + 7 \right) \), with \( r > A_k r_h \)
- \( \frac{3}{2} < k < 2 \), with \( r < A_k r_h \).

A positive energy density in a region that rests outside the horizon is only possible in the second of the above cases.

The effective energy-momentum tensor is anisotropic. The radial pressure \( p_r^\phi (r) \) in the \( r \) direction is given by

\[
p_r^\phi (r) = \pm r^{\frac{5+4k}{1-k}} \left( 3k(1-k)(1-r)^{\frac{4k-5}{1-k}} + k - 2 \right),
\]

while the isotropic tangential pressure in the \( x \) and \( y \) directions is

\[
p_T^\phi = p_r^\phi (r) = p_y^\phi (r) = \pm r^{\frac{2k+2}{1-k}} \left( -6k^2 + 7k + 1 \right) m + 2k(2-k)(1-k)r \frac{3+4k}{1-k}.
\]

We can define the mean pressure \( p_\phi = \frac{1}{3} \left( p_r^\phi + p_y^\phi + p_T^\phi \right) \) and with respect to the latter write a “mean” equation of state parameter \( w_\phi (r) = \frac{p_r^\phi (r)}{p_\phi (r)} \).

What we may observe is that near the curvature singularity \( r \to 0 \) and for the values of \( k \) corresponding to solution (31) the equation of state parameter has the limit \( w_\phi \ (r \to 0) = \frac{1}{2} \).

That “anisotropic” radiation fluid is provided by the extra terms of \( f (R) \)-gravity [99]. We can now proceed with the study of the analytical solution in the Einstein frame.

5 Black branes in the Einstein frame

At this point we can map the results expressed in the previous section to the Einstein frame by performing transformation (16). After a reparametrization with respect to the \( r \) variable the resulting spacetime becomes

\[
ds^2 = -r^2 \left( \frac{\frac{2k-1}{3(k-1)} - 1}{m} r - r^{\frac{2k+2}{3(k-1)}} + 2k(2-k)(1-k)r \frac{3+4k}{3(k-1)} \right) dt^2
\]

\[
+ \left( 1 - 2k \right)^2 \frac{r^{\frac{2k+2}{3(k-1)}}}{m} - 1 + r^2 \left( dy^2 + dz^2 \right).
\]

for \( 1 < k < \frac{5}{4} \) or

\[
ds^2 = -r^2 \left( \frac{\frac{2k-1}{3(k-1)} - 1}{m} r - r^{\frac{2k+2}{3(k-1)}} + 2k(2-k)(1-k)r \frac{3+4k}{3(k-1)} \right) dt^2
\]

\[
+ \left( 1 - 2k \right)^2 \frac{r^{\frac{2k+2}{3(k-1)}}}{m} - 1 + r^2 \left( dy^2 + dz^2 \right).
\]

for \( k \in \left( -\infty, 1 \right) \bigcup \left( \frac{5}{4}, +\infty \right) - \left\{ \frac{3}{2} \right\} \). The corresponding minimally coupled scalar field that satisfies Einstein’s equations

\[
R_{\mu \nu} - \frac{1}{2} R g_{\mu \nu} = T_{\mu \nu},
\]

is

\[
\phi (r) = \frac{2(k-2)}{\sqrt{3} (k-1)} \ln r
\]

with a potential given by

\[
\hat{V} (\phi) = \pm \frac{6(4k-5)e^{\frac{(k-2)(k+4)}{2(4k+5)}}}{2k-1}.
\]

Again the plus sign corresponds to solution (40), while the minus is reserved for (41).

Unlike the previous case, where we have a curvature singularity hidden by an horizon (thus a black brane/string) for a specific range of the parameter \( k \), here we can see that a singularity is always present at \( r = 0 \). The Ricci scalar of the resulting spacetimes is

\[
R = \pm \frac{6}{(1-2k)^2 m} \left[ \frac{10k^2 - 22k + 13}{3(k-1)^2} \times \left( 3(5k^2 - 8k + 2)m \frac{(2k-1)(4k+5)}{3(k-1)^2} + (k-2)^2 \right) \right]
\]

and it can be seen that

\[
- \frac{10k^2 - 22k + 13}{3(k-1)^2} < 0,
\]

\[
\text{and} \quad \frac{(2k-1)(4k+5)}{3(k-1)^2} \leq \frac{10k^2 - 22k + 13}{3(k-1)^2}
\]

hold for all \( k \neq 1 \), with the equality in the latter expression being true for \( k = 2 \). Thus, we can derive that \( R \) is singular at \( r = 0 \) for all values, but \( k = 1 \) or \( k = 2 \). The first is already excluded from our analysis, while the latter leads to a constant \( R \). However, this does not prevent a curvature singularity for \( k = 2 \); As we can observe from the Kretschmann scalar

\[ \odot \] Springer
The singularity is at $r = 0$ from (43) and as a result the potential $\phi$ becomes a constant. We can write in this case the line element as

$$
d s^2 = -\left( r^2 - \frac{1}{R} \right) d t^2 + \frac{12}{R} \left( \frac{1}{r} - r^2 \right)^{-1} d r^2 + r^2 \left( d y^2 + d z^2 \right)$$

(48)

with $\tilde{V} = \frac{R}{r}$, where $R$ is the now constant Ricci scalar. Solution (48) is a known black string solution in the case of a pure cosmological constant and a special case of a more general solution presented in [100]. The horizon that hides the singularity is at $r = r_H$, where

$$
r_H = m - \frac{3k - 1}{2k - 1} \frac{1}{12(14k - 5)}$$

(49)

(of course, for the aforementioned solutions, we consider $m > 0$).

As a result of the previous considerations, we can immediately see how the conformal transformation that takes us from the Jordan to the Einstein frame, changes the gravitational properties of the solution. A black brane/string is now admissible for all values of the parameter $k$ for which the solution holds. Something which did not happen in the $f(R)$ or the O’Hanlon theory. Although the two frames are conformally equivalent this does not mean that they are physically equivalent. Solutions can be mapped at a purely mathematical level, but their study produces in principle different results.

We can also write the basic components of the effective fluid generated by the scalar field in this case. The energy density $\rho = -T^0_0$ is given by

$$
\rho = \pm \frac{3r}{(1 - 2k)^2 m} \left[ 3 \left( \frac{2k - 1}{14k - 5} \right) (7k - 10k + 1)m + (k - 2)^2 \right].
$$

(50)

The radial pressure $p_r = T^1_1$ is expressed as

$$
p_r = \pm \frac{3r}{(1 - 2k)^2 m} \left[ (k - 2)^2 - 9r \left( \frac{2k - 1}{14k - 5} \right) (k - 1)^2 m \right],
$$

(51)

while the tangential pressure in this case is $p_T = p_x = p_y = T^2_2 = T^3_3 = -\rho$. Thus, we can see that in this case a “partial” equation of state $w_1 = \frac{p_r}{\rho} = -1$ is satisfied in the $x$ and $y$ directions. It can be easily verified that $\rho$ is positive in the region $1 < k < \frac{5}{4}$, if the radius $r$ satisfies $r > Bkr_H$, where

$$
B_k = \left( \frac{k - 2}{7k^2 - 10k + 1} \right) \frac{3k - 1}{2k - 1} \frac{1}{12(14k - 5)}. 
$$

(52)

In the second region of the solution $k < 1$, $k > \frac{5}{4}$, $k \neq 12$, the energy density can only be positive in the subsets $\frac{1}{5} \left( 5 - 3\sqrt{2} \right) < k < 1$ and $\frac{5}{4} < k < \frac{1}{7} \left( 3\sqrt{2} + 5 \right)$ given that the radius is again greater than $Bkr_H$. It is also now interesting to study the basic thermodynamic quantities to compare with those derived for (30) and (31) in [88].

At this point we have to note that solutions (40) and (41) truly represent different gravitational systems in comparison to (30) and (31). As we mentioned before, a conformal transformation does not necessarily correspond to a general coordinate transformation, and this is what happens in the specific case that we study here. Line elements (40) and (41) describe different geometries (thus distinct gravitational fields) than those of (30) and (31). The latter can be easily verified by constructing and comparing invariant relations between gravitational scalars. In this sense we can talk about a physical in-equivalence between the two frames, since the ensuing gravitational field in the respective conformally related theories is genuinely different.

6 Temperature and entropy

In this section we calculate some basic thermodynamic quantities like the temperature and the entropy. At first, we can perform a transformation $t \mapsto \tau$ to bring the metric into an ingoing Eddington–Finkelstein coordinate system. Thus, if we impose

$$
t = \tau \pm \int_0^r \frac{\sqrt{g_{rr}}}{-g_{tt}} dr, 
$$

(53)

the line elements (40) and (41) are transformed into

$$
ds^2 = \pm r^2 \left( 1 - \frac{r}{m} \left( \frac{2k - 1}{14k - 5} \right) \frac{1}{12(14k - 5)} \right) d \tau^2 \pm \frac{2(2k - 1)}{3(k - 1)} r \frac{\sqrt{2}}{m} d \tau dr + r^2 \left( d y^2 + d z^2 \right).
$$

(54)

with the plus sign corresponding to solution (40) and the minus to (41). In these coordinates, the surface gravity can either be given by $\kappa = \Gamma^1_{r r} |_{r = r_H}$ or—with the help of the
timelike Killing vector \( X^\mu = \delta_4 \) that exhibits a Killing horizon at \( r = r_H \) by \( \kappa = \nabla_\mu (X^\nu X_\nu)|_{r=r_H} = -2\kappa X_\mu |_{r=r_H}. \)

In any case, the result is

\[
\kappa = \pm \frac{(5 - 4k)}{2(k-1)} m^{-\frac{2k^2+2k+1}{2k^2+4k-5}}.
\]

It is rather impressive that the surface gravity is exactly the same with the one derived in [88] for a different set of space-times, namely (32) and (30) that correspond to the relative solutions in \( f(R) = R^k \) gravity and which are connected to (40) and (41) through a conformal transformation. We note that once again the plus sign corresponds to the case \( 1 < k < \frac{5}{2} \), while the minus is for \( k < 1, k > \frac{5}{2}, k \neq \frac{1}{2} \). As a result of \( \kappa \) being the same in the two frames, the resulting temperatures at the horizon are also identical. We can see that the latter is given in terms of the single essential constant of the geometry \( m \) and the parameter of the theory \( k \) as:

\[
T = \frac{\kappa}{2\pi} = \begin{cases}
\frac{\sqrt[5]{-4k}}{2\pi(k-1)} m^{-\frac{2k^2+2k+1}{2k^2+4k-5}}, & 1 < k < \frac{5}{4} \\
\frac{\sqrt[5]{-2k^2+2k+1}}{2\pi(k-1)} m^{-\frac{2k^2+2k+1}{2k^2+4k-5}}, & k \in (-\infty, 1) \cup (\frac{5}{4}, +\infty) - \{\frac{1}{2}\}
\end{cases}
\]

with each branch corresponding to the appropriate solution for the assumed values of \( k \). The exponent of \( m \) in the expressions appearing in (56) is negative in the region \( \frac{1}{2} < k < \frac{5}{4} \) and when \( k > \frac{1}{2}(1+\sqrt{3}) \) or \( k < \frac{1}{2}(1-\sqrt{3}) \), which are the roots of the polynomial in the nominator. On the other hand, we have the inverse situation when \( \frac{1}{2}(1-\sqrt{3}) < k < \frac{1}{2} \) and \( \frac{5}{4} < k < \frac{1}{2}(1+\sqrt{3}) \).

At this point we can write down the area per unit length

\[
\sigma = 2\pi r^2_H = 2\pi m^{-\frac{6(k-1)^2}{2k^2+4k-5}}.
\]

In this manner, we can define an entropy per unit length as

\[
S \sim \frac{\sigma}{4} = \frac{\pi}{2} m^{-\frac{6(k-1)^2}{2k^2+4k-5}}.
\]

We can see that the power of \( m \) is positive when \( k \in (\frac{1}{2}, \frac{5}{4}) - \{1\} \), while it is negative for all the other values (excluded of course \( k = \frac{1}{2}, \frac{5}{4} \)). The entropy is always well defined and positive for all admissible values of \( k \), in contrast to what happens to the corresponding solution in the Jordan frame. i.e. the one expressed previously in the context of the \( f(R) \) theory. In the latter, the entropy per unit length can be found to be [88]

\[
S_{f(R)} \sim k \left( \pm \frac{k(4k-5)}{(k-1)(2k-1)} \right)^{k-1} m^{-\frac{6(k-1)^2}{2k^2+4k-5}}.
\]

The \( S_{f(R)} \) of \( f(R) = R^k \) gravity is positive only in the cases where \( 0 < k < \frac{1}{2} \) or when \( k \) is a negative even integer. This is another difference in the physics of the system owed to the conformal transformation linking the two theories. In Einstein’s gravity with the minimally coupled scalar field the solution results in a positive entropy for all values of the parameter characterizing the potential of the scalar field. We can note however, that the dependence in what regards the constant \( m \) appearing in the line element remains the same in the two theories.

In both frames the corresponding solution in not asymptotically maximally symmetric. This results in complications in what regards a possible calculation of the mass of the system. Even in the Einstein frame, an indirect computation through the first law of thermodynamics is not trivial due to the contributing work due to the matter source which is characterized by a non constant pressure. This is why we restrict ourselves to carry on the comparison only over the well defined thermodynamic quantities of the temperature and the entropy.

7 Conclusions

In this work we have studied analytical solutions of black branes which are related through conformal transformations. According to our knowledge this is the first examples where black brane solutions are compared between the Jordan and the Einstein frame. At the Jordan frame we consider an analytic solution which was derived recently for \( f(R) \)-gravity in the metric formalism; more specifically in the context of a power law \( f(R) = R^k \) theory over an axisymmetric space-time in vacuum. The conformal equivalent theory in the Einstein frame corresponds to a scalar field with an exponential potential.

In principle it is expected that not only the physical but also the geometrical properties are different when one passes from one frame to the other. This can be attributed to the fact that conformal transformations do not necessarily correspond to a general coordinate transformation. The latter constitute the gauge freedom transformations of gravitational theories and hence map different line elements describing the same geometry. As a result, when a conformal transformation is performed, the resulting space-time may in principle possess extremely different properties. In our case we where able to witness several striking differences but also a few similarities.

The analytic solution in the Jordan frame was found to describe black branes (solutions with a singularity at \( r = 0 \) that is encompassed by a horizon \( r = r_H \)) only for specific values of the free parameter \( k \). Moreover, it has been shown that the entropy of these black brane solutions is positive only for specific values of \( k \), and more specifically when \( 0 < k < \frac{1}{2} \) or when \( k \) is a negative, even integer. The parameter \( k \) in the \( f(R) = R^k \) theory being the power in which the Ricci scalar is raised, while in the Einstein theory is the exponent in the exponential potential characterizing the scalar field.
In contrast to what happened in the Jordan frame, the conformally equivalent solution in the Einstein frame was found to describe black branes for all the admissible real values of the parameter $k$, while the entropy was calculated to be well defined, i.e. positive, for all the values of this parameter. We can also note that the horizon $r_H$ in the Einstein frame is shifted $r_H \neq r_h$ when we make the comparison by keeping the same constant $m$ appearing in the two geometries.

A similarity that may be noticed in the two solutions is that the black objects that they describe are in neither case asymptotically maximally symmetric. Additionally, the surface gravity on the horizon ends up to be the same for both cases. A property which results in the same relation for the thermodynamic temperature as well.

When seeing the solution in the Jordan frame as a result of the O’Hanlon theory, we calculated the energy density and anisotropic pressure of the respective effective fluid. It was interesting to note that, in this situation, by approaching the curvature singularity, the solution looks like the effect of a radiation fluid. We also derived the relative expressions in context of Einstein’s gravity and we investigated for which ranges of the parameter $k$ characterising the two models, the weak energy condition is satisfied.

From all of the above results it follows that the basic physical properties of the aforementioned axisymmetric solutions do not survive through the conformal transformation connecting them. Indeed, horizons, the entropy and even singularities change between the two systems. The effect of the latter being the alteration of the conditions over the parameter $k$ needed in order to identify the solution as a black brane. In a forthcoming work we want to compare the two theories by studying dynamical evolution of test particles among the two different solutions.
