INTRODUCTION

Hemifacial spasm (HFS) is a clinical syndrome characterized by unilateral facial nerve dysfunction. The usual cause involves vascular compression of the seventh cranial nerve, but compression by an artery passing through the facial nerve is very unusual. A 20-year-old man presented with left facial spasm that had persisted for 4 years. Compression of the left facial nerve root exit zone by the anterior inferior cerebellar artery (AICA) was revealed on magnetic resonance angiography. During microvascular decompression surgery, penetration of the distal portion of the facial nerve root exit zone by the AICA was observed. At the penetrating site, the artery was found to have compressed the facial nerve and to be immobilized. The penetrated seventh cranial nerve was longitudinally split about 2 mm. The compressing artery was moved away from the penetrating site and the decompression was secured by inserting Teflon at the operative site. Although the facial spasm disappeared in the immediate postoperative period, the patient continued to show moderate facial weakness. At postoperative 12 months, the facial weakness had improved to a mild degree. Prior to performing microvascular decompression of HFS, surgeons should be aware of a possibility for rare complex anatomy, such as compression by an artery passing through the facial nerve, which cannot be observed by modern imaging techniques.

Key Words : Hemifacial spasm · Penetrating artery · Facial nerve · Facial weakness.

CASE REPORT

A 20-year-old male patient presented with a 4-year history of progressive HFS beginning with left orbicularis oris spasms, often triggered by eating or drinking. He described the spasms as progressing from the mouth to the eye and eventually involving the platysma, which is unusual in typical HFS. The patient’s hearing was normal and he exhibited no cranial nerve palsy or neurological deficits.

Concentric needle electromyography examination of the left orbicularis oculi revealed irregular bursting discharge at rest and normal motor unit potential on volition. Also, evidence of synkinesis in the orbicularis oculi and mentalis muscle was observed during supraorbital nerve stimulation. Magnetic resonance imaging (MRI) and magnetic reso-
nance angiography (MRA) revealed a compression of the left facial nerve root exit zone by the AICA (Fig. 1).

Based on the above, microvascular decompression was selected for treatment. During the operation, penetration of the distal portion of the facial nerve root exit zone by the AICA was observed. At the penetrating site, the artery was found to have compressed the facial nerve and to be immobilized. After discussing the risk of facial paresis with the patient's family, the penetrated seventh cranial nerve was longitudinally split about 2 mm. The compressing artery was moved away from the penetrating site and the decompression was secured by inserting Teflon at the operative site (Fig. 2).

Although the facial spasm disappeared in the immediate postoperative period, the patient continued to show moderate facial weakness. At postoperative 4 months, the facial weakness had improved to a mild degree (Fig. 3).

**DISCUSSION**

HFS is a benign condition, characterized by unilateral paroxysmal chaotic and clonic spasms of the orbicularis oculi, perinasal, perioral and platysma muscles. Most cases of HFS are due to a vascular pathology that compresses the exiting nerve root of nerve VII. In a previous study, Han et al. reviewed 1642 cases of HFS to evaluate unusual possible causes and clinical presentations, and reported that 1633 cases (99.4%) involved neurovascular compression. The other unusual causes were a secondary causative structural lesion (0.5%), a tumor (0.4%) and a vascular malformation (0.1%).

Upon literature review, the most common causes of HFS, besides neurovascular compression, were cerebellopontine angle tumors (epidermoid, arachnoid cyst, lipoma, and vestibular schwannoma), and other unusual causes including cerebellopontine angle medullary venous malformations, Paget's disease, occipital falcine meningioma, cerebellopontine angle meningioma, acoustic schwannoma, pontine glioma, fourth ventricle ganglioglioma, pontine infarction, syringobulbia, multiple sclerosis, trauma, hypothyroidism, idiopathic intracranial hypertension, vertebrobasilar ectasia, craniovertebral anomalies, glomus jugular tumor, parotid gland, and arterial hypertension. A few cases of HFS alone or in combination with trigeminal neuralgia have been reported as a false localizing sign in patients who had a contralateral posterior fossa mass or acoustic neuroma. This present case involved an unusual cause of HFS, and there have been no reports of HFS caused by penetration of the nerve by an artery.

From an embryological point of view, the beginning of the facial nerve, the facioacoustic primordium, appears during the third week of gestation. The facial nerve then splits into two parts at the end of the fourth week and is complete by the fifth to sixth gestational week. Accordingly, we surmised that the penetration of the nerve may have happened as the AICA attempted to pass through the split in the facial nerve that appears at the fifth to sixth gestational week.

The introduction of MRI and MRA has improved the detection of neurovascular conflicts (vascular contact and/or compression of the root exit zone of the facial nerve). High-resolution MRI and MRA techniques highly sensitive for neurovascular conflict are frequently needed. These imaging studies generally show great sensitivity in detecting unusual causes of HFS; however, in the present case, such imaging studies failed to reveal the penetration of the nerve by the AICA, as shown in Fig. 1.

Unusual Cause of Hemifacial Spasm

CH Oh, et al.

which to completely relieve the facial spasm, but rather to partially relieve with the preservation of facial weakness.

CONCLUSION

Prior to performing microvascular decompression of HFS, surgeons should be aware of a possibility for rare complex anatomy, such as compression by an artery passing through the facial nerve, which cannot be observed by modern imaging techniques.
