Abstract

We examine how large violation of CP and T is allowed in long baseline neutrino experiments. When we attribute only the atmospheric neutrino anomaly to neutrino oscillation we may have large CP violation effect. When we attribute both the atmospheric neutrino anomaly and the solar neutrino deficit to neutrino oscillation we may have a sizable T violation effect proportional to the ratio of two mass differences; it is difficult to see CP violation since we can’t ignore the matter effect. We give a simple expression for T violation in the presence of matter.

1 Introduction

The CP or T violation is a fundamental and important problem of the particle physics and cosmology. The CP study of the lepton sector, though it has been less examined than that of quark sector, is indispensable, since the neutrinos are allowed to have masses and complex mixing angles in the electroweak theory.

The neutrino oscillation search is a powerful experiment which can examine masses and mixing angles of the neutrinos. In fact the several underground experiments have shown lack of the solar neutrinos\(^\text{[1, 2, 3, 4]}\) and anomaly in the atmospheric neutrinos\(^\text{[5, 6, 7, 8, 9]}\), implying that there may occur the neutrino oscillation. The atmospheric neutrino anomaly suggests mass difference around \(10^{-3} \sim 10^{-2}\) eV\(^2\)\(^\text{[10, 11, 12]}\), which encourages us to make long base line neutrino experiments. Recently such experiments are planned and will be operated in the near future\(^\text{[13, 14]}\). It seems necessary for us to examine whether there is a chance to observe not only the neutrino oscillation but also the CP or T violation by long base line experiments. In this short paper we study such possibilities taking account of the atmospheric neutrino experiments and also considering the solar neutrino experiments and others.

2 Formulation of CP and T violation in neutrino oscillation

2.1 Brief review

We briefly review CP and T violation in vacuum oscillation\(^\text{[15, 16, 17]}\) to clarify our notation.

Let’s denote the mass eigenstates of 3 generations of neutrinos by \(\nu_m = (\nu_1, \nu_2, \nu_3)\) with mass eigenvalues\(^\text{[1]}\)(\(m_1, m_2, m_3\)) and the weak eigenstates by \(\nu_w = (\nu_e, \nu_\mu, \nu_\tau)\) corresponding to electron, \(\mu\) and \(\tau\), respectively. They are connected by a unitary transformation:

\[
\nu_w = U \nu_m, \tag{1}
\]

where \(U\) is a unitary \((3 \times 3)\) matrix similar to the CKM matrix for quarks. We will use the parametrisation for \(U\) by Chau and Keung\(^\text{[18, 19, 20]}\),

\[
U = \begin{pmatrix}
1 & 0 & 0 \\
0 & c_\psi & s_\psi \\
0 & -s_\psi & c_\psi
\end{pmatrix}
\begin{pmatrix}
1 & 0 & 0 \\
0 & c_\phi & s_\phi \\
0 & e^{i\delta} & c_\phi
\end{pmatrix}
\begin{pmatrix}
c_\omega & s_\omega & 0 \\
s_\omega & c_\omega & 0 \\
0 & 0 & 1
\end{pmatrix}, \tag{2}
\]

where the \(\lambda\)’s are the Gell-Mann matrices.

\(^1\) We assume \(m_1 < m_2 < m_3\) in vacuum.
The evolution equation for the weak eigenstate is given by

\[ i \frac{d}{dx} \nu_w = -U \text{diag}(p_1, p_2, p_3) U^\dagger \nu_w \]

\[ \simeq \{ -p_1 + \frac{1}{2E} U \text{diag}(0, \delta m^2_{21}, \delta m^2_{31}) U^\dagger \} \nu_w \]

\[ \simeq \frac{1}{2E} U \text{diag}(0, \delta m^2_{21}, \delta m^2_{31}) U^\dagger \nu_w, \quad (4) \]

where \( p_i \)'s are the momenta, \( E \) is the energy and \( \delta m^2_{ij} = m_i^2 - m_j^2 \). A term proportional to a unit matrix like \( p_1 \) in eq.4 is dropped because it is irrelevant to the transition probability.

The solution for the equation is

\[ \nu_w(x) = U \exp(-i \frac{x}{2E} \text{diag}(0, \delta m^2_{21}, \delta m^2_{31})) U^\dagger \nu_w(0). \quad (5) \]

The transition probability of \( \nu_\alpha \rightarrow \nu_\beta (\alpha, \beta = e, \mu, \tau) \) at distance \( L \) is given by

\[ P(\nu_\alpha \rightarrow \nu_\beta; E, L) = | \sum_{i,j} U_{\beta i}^* (e^{-i \frac{L}{2E} \text{diag}(0, \delta m^2_{21}, \delta m^2_{31})})_{ij} U_{\alpha j}^* |^2 \]

\[ = \sum_{i,j} U_{\beta i}^* U_{\beta j}^* U_{\alpha i} U_{\alpha j} \exp\{-i \delta m^2_{ij} (L/2E)\}. \quad (6) \]

The T violation gives the difference between the transition probability of \( \nu_\alpha \rightarrow \nu_\beta \) and that of \( \nu_\beta \rightarrow \nu_\alpha \): [21]

\[ P(\nu_\alpha \rightarrow \nu_\beta; E, L) - P(\nu_\beta \rightarrow \nu_\alpha; E, L) = -4(\text{Im} U_{\beta 1} U_{\beta 2}^* U_{\alpha 1}^* U_{\alpha 2}) (\sin \Delta_{21} + \sin \Delta_{32} + \sin \Delta_{13}) \]

\[ \equiv 4Jf, \quad (7) \]

where

\[ \Delta_{ij} \equiv \frac{\delta m^2_{ij} L}{2E} = 2.54 \frac{(\delta m^2_{ij}/10^{-2}\text{eV}^2)}{(E/\text{GeV})} (L/100\text{km}), \quad (10) \]

\[ J \equiv -\text{Im} U_{\beta 1} U_{\beta 2}^* U_{\alpha 1}^* U_{\alpha 2}, \quad (11) \]

\[ f \equiv (\sin \Delta_{21} + \sin \Delta_{32} + \sin \Delta_{13}) \]

\[ = -4 \sin \frac{\Delta_{21}}{2} \sin \frac{\Delta_{32}}{2} \sin \frac{\Delta_{13}}{2}. \quad (12) \]

The unitarity of \( U \) gives

\[ J = \pm \sin \omega \cos \omega \sin \psi \cos \psi \sin \phi \cos^2 \phi \sin \delta \quad (14) \]

with the sign + (−) for \( \alpha, \beta \) in cyclic (anti-cyclic) order(+) for \( (\alpha, \beta) = (e, \mu), (\mu, \tau) \) or \( (\tau, e) \). In the following we assume the cyclic order for \( (\alpha, \beta) \) for simplicity.

There are bounds for \( J \) and \( f \),
\[ |J| \leq \frac{1}{6\sqrt{3}}, \]  
(15)

where the equality holds for \(|\sin \omega| = 1/\sqrt{2}, |\sin \psi| = 1/\sqrt{2}, |\sin \phi| = 1/\sqrt{3}\) and \(|\sin \delta| = 1\), and \[|f| \leq \frac{3\sqrt{3}}{2},\]  
(16)

where the equality holds for \(\Delta_{21} \equiv \Delta_{32} \equiv 2\pi/3 \pmod{2\pi}\).

In the vacuum the CPT theorem gives the relation between the transition probability of anti-neutrino and that of neutrino,

\[ P(\bar{\nu}_\alpha \to \bar{\nu}_\beta; E, L) = P(\nu_\beta \to \nu_\alpha; E, L), \]  
(17)

which relates CP violation to T violation:

\[ P(\nu_\alpha \to \nu_\beta; E, L) - P(\bar{\nu}_\alpha \to \bar{\nu}_\beta; E, L) = P(\nu_\alpha \to \nu_\beta; E, L) - P(\nu_\beta \to \nu_\alpha; E, L). \]  
(18)

### 2.2 CP and T violation with disparate mass differences

Let’s consider how large the T(CP) violation can be in the “disparate” mass difference case, say \(\epsilon \equiv \frac{\delta m^2_{31}}{\delta m^2_{21}} \ll 1\). In this case the following two situations are interesting, since in the case \(\Delta_{31} \ll 1\) we have too small \(f(\sim O(\epsilon \Delta^2_{31}))\) due to eq.(13) to observe the T(CP) violation effect:

**Situation 1.** \(\Delta_{31} \sim O(1)\).

Because \(|\epsilon \Delta_{31}| \ll 1\) in this case, the oscillatory part \(f\) becomes \(O(\epsilon)\):

\[ f(\Delta_{31}, \epsilon) = \sin \Delta_{21} + \sin \Delta_{32} + \sin \Delta_{13} = \sin(\epsilon \Delta_{31}) + \sin\{(1 - \epsilon)\Delta_{31}\} - \sin \Delta_{31} \]  
(19)

\[ = \epsilon \Delta_{31}(1 - \cos \Delta_{31}) + O(\epsilon^2 \Delta^2_{31}). \]  
(20)

Fig.\(\text{II}\) shows the graph of \(f(\Delta_{31}, \epsilon = 0.03)\). The approximation eq.\(\text{20}\) works very well up to \(|\epsilon \Delta_{31}| \sim 1\). In the following we will use eq.\(\text{20}\) instead of eq.\(\text{19}\). We see many peaks of \(f(\Delta_{31}, \epsilon)\) in fig.\(\text{II}\). In practice, however, we do not see such sharp peaks but observe the value averaged around there, for \(\Delta_{31}\) has a spread due to the energy spread of neutrino beam \(|\delta \Delta_{31}/\Delta_{31}| = |\delta E/E|\). In the following we will assume \(|\delta \Delta_{31}/\Delta_{31}| = |\delta E/E| = 20\%\) \(\text{23}\) as a typical value.

Table \(\text{II}\) gives values of \(f(\Delta_{31}, \epsilon)/\epsilon\) at the first several peaks and the averaged values around there.

---

\(^2\) Hereafter we denote the larger mass difference by \(\delta m^2_{31}\) and the smaller one by \(\delta m^2_{21}\) in the case that the mass differences have a large ratio.
Figure 1: Graph of $f(\Delta_{31}, \epsilon)$ for $\epsilon = 0.03$. The solid line and the dashed line represent the exact expression eq.13 and the approximated one eq.20, respectively. The approximated $f$ has peaks at $\Delta_{31} \approx 3.67, 9.63, 15.8, \ldots$ irrespectively of $\epsilon$.

| $\Delta_{31}$ | $f/\epsilon$ | $< f/\epsilon >_{10\%}$ | $< f/\epsilon >_{20\%}$ |
|----------------|---------------|-----------------|-----------------|
| 3.67           | 6.84          | 6.75            | 6.48            |
| 9.63           | 19.1          | 17.6            | 14.0            |
| 15.8           | 31.5          | 25.7            | 15.6            |
| ...            | ...           | ...             | ...             |

Table 1: The peak values of $f(\Delta_{31}, \epsilon)/\epsilon$ and the corresponding averaged values. Here $< f/\epsilon >_{20\% (10\%)}$ is a value of $f(\Delta_{31}, \epsilon)/\epsilon = \Delta_{31}(1 - \cos \Delta_{31})(\text{see eq.20})$ averaged over the range $0.8\Delta_{31} \sim 1.2\Delta_{31}$ ($0.9\Delta_{31} \sim 1.1\Delta_{31}$).

We see the T violation effect,

$$< P(\nu_\alpha \rightarrow \nu_\beta) - P(\nu_\beta \rightarrow \nu_\alpha) >_{20\%} = 4J < f >_{20\%} = J\epsilon \times \begin{cases} 25.9 \\
56.0 \\
62.4 
\end{cases} \text{ for } \Delta_{31} = \begin{cases} 3.67 \\
9.63 \\
15.8 \end{cases} \text{ (21)}$$

at peaks for neutrino beams with 20 % of energy spread. Note that the averaged peak values decrease with the spread of neutrino energy.

Which peak we can reach depends on $\delta m_{31}^2$, $L$ and $E$. The first peak $\Delta_{31} = 3.67$ is reached, for example by $\delta m_{31}^2 = 10^{-2}$ eV$^2$, $L = 250$ km (for KEK-Kamiokande long base line experiment) and neutrino energy $E = 1.73$ GeV. In this case we see the T(CP) violation effect at best of $|25.9J\epsilon| \leq 2.50\epsilon$ since we have a bound on $J$ as eq.13.
Situation 2. $\Delta_{31} \gg 1$.

Because $\sin \Delta_{32}$ and $\sin \Delta_{13}$ oscillate rapidly and vanish after being averaged over the energy spread in this case, the oscillatory part $f$ is dominated by $\sin \Delta_{21}$. Since $f$ has now a bound $|f| \leq 1$ instead of eq.16, the $T$ violation effect $4Jf$ is bounded as $|4Jf| \leq |4J|$.

(For energy spread of $10 \sim 20\%$ of neutrino beam, $\Delta_{31} > 30$ is enough for $\sin \Delta_{32}$ and $\sin \Delta_{13}$ to oscillate rapidly and vanish after being averaged.)

3 CP violation

There are a variety of possible combinations of the parameters, three mixing angles, two mass differences and a CP violating phase. When we consider only the atmospheric neutrino anomaly to be attributed to the neutrino oscillation, we can take the mass differences, $\delta m^{2}_{21}$ and $\delta m^{2}_{31}$ (and hence $\delta m^{2}_{32}$), to be comparable, while when we consider both the solar and the atmospheric neutrino anomalies to be attributed to the neutrino oscillation, we expect $\delta m^{2}_{21}$ and $\delta m^{2}_{31}$ to be “disparate”, $\delta m^{2}_{21}/\delta m^{2}_{31} \ll 1$.

We investigate how large the CP violation effect can be in neutrino oscillation for the above two cases.

3.1 Comparable mass difference case

Let’s examine the case of mass differences to be of the same order of magnitude.

We use a parameter set that $(\delta m^{2}_{21}, \delta m^{2}_{31}) = (3.8, 1.4) \times 10^{-2}$ eV$^2$, $(\omega, \phi, \psi) = (19^\circ, 43^\circ, 41^\circ)$ and $\delta$ is arbitrary, derived by Yasuda through the analysis of the atmospheric neutrino anomaly. Here the matter effect is negligibly small and eq.18 is available.

With use of eq.9, eq.14, and eq.18 this parameter set gives the CP violation effect

$$P(\nu_\alpha \rightarrow \nu_\beta) - P(\bar{\nu}_\alpha \rightarrow \bar{\nu}_\beta) = 0.22 \sin \delta f(x),$$

where

$$f(x) = (\sin 3.8x + \sin 2.4x - \sin 1.4x),$$

and

$$x = 2.5 \frac{(L/100\text{km})}{(E/\text{GeV})}. \quad (24)$$

Fig. shows the oscillatory part $f(x)$. There are many peaks $f(x)$ showing the possibility to observe the large CP violation effect. For example, we may see very large difference between the transition probabilities, $< P(\nu_\alpha \rightarrow \nu_\beta) - P(\bar{\nu}_\alpha \rightarrow \bar{\nu}_\beta) > 20\% \sim 0.4 \sin \delta$ for $L = 250$ km (for KEK-Kamiokande experiment) and $E \sim 4.5$ GeV corresponding to $x \sim 1.4$, if we have large $\sin \delta$. 

\[ f(x) \equiv \sin 3.8x + \sin 2.4x - \sin 1.4x \]

Figure 2: Graph of \( f(x) \) of eq.23. There are high peaks (positive or negative) at \( x = 0.42, 1.4, 3.6, 4.6 \cdots \). Values of \( f(x) \) at peaks averaged over energy spread of 10%~20% are \(< f(0.42) > = 1.3 \sim 1.3, < f(1.4) > = -1.9 \sim -1.8, < f(3.6) > = 2.2 \sim 1.4, < f(4.6) > = -1.5 \sim -0.40 \cdots \).

Incidentally we may remark that the survival probability of solar neutrino is calculated to be 0.45 for those mixing angles. This value is consistent with both two gallium experiments\[1, 2\] and Kamiokande experiment\[3\], but it is inconsistent with Homestake result\[4\], if all the solar neutrino anomaly should be attributed to the neutrino oscillation\[26\].

In conclusion we may see a large CP violation effect when we have comparable mass differences. In this respect we note that the long base line experiments are urgently desirable.

### 3.2 Disparate mass difference case

Next we consider the “disparate” mass difference case \( \delta m_{21}^2 / \delta m_{31}^2 \ll 1 \).

The case \( \delta m_{31}^2 \sim 1 \text{ eV}^2 \) and \( \delta m_{21}^2 \sim 10^{-2} \text{ eV}^2 \) is favoured by the hot dark matter scenario\[27\] and the atmospheric neutrino anomaly. This case is already analysed by Tanimoto\[28\] and we will not discuss it here.

The case \( \delta m_{31}^2 \sim 10^{-2} \text{ eV}^2 \) and \( \delta m_{21}^2 \sim 10^{-4} \text{ eV}^2 \) could typically explain the anomalies of the atmospheric and the solar neutrinos\[11\]. In this case we cannot neglect the matter effect\[24, 25\]

\[
2\sqrt{2} G_F n_e E \sim 2 \times 10^{-4} \text{eV}^2 \left( \frac{E}{\text{GeV}} \right) \left( \frac{n}{3\text{g/c.c.}} \right),
\]

where \( n_e \) is the electron number density of the earth and \( n \) is the matter density of the surface of the earth, since it is greater than \( \delta m_{21}^2 \). It requires to subtract such effect in order to deduce the pure CP violation effect\[29\]. In principle it is possible, because the matter effect is proportional to \( E \) while \( \delta m_{21}^2 \) is constant.
4 T violation

In the matter with constant density\footnote{Note that the time reversal of $\nu_\alpha \rightarrow \nu_\beta$ requires the exchange of the production point and the detection point and the time reversal of $P(\nu_\alpha \rightarrow \nu_\beta)$ in matter is in general different from $P(\nu_\beta \rightarrow \nu_\alpha)$\footnote{1}} we have a pure T violation effect $P(\nu_\alpha \rightarrow \nu_\beta) - P(\nu_\beta \rightarrow \nu_\alpha)$, though we do not observe a pure CP violation effect because of an apparent CP violation due to matter.

4.1 T violation in matter

When a neutrino is in matter, its matrix of effective mass squared $M_m^2$ of weak eigenstates is\textsuperscript{[19, 20]}

$$M_m^2 = U \left( \begin{array}{cc} 0 & \delta m_{21}^2 \\ \delta m_{31}^2 & \delta m_{31}^2 \end{array} \right) U^\dagger + \left( \begin{array}{cc} a & 0 \\ 0 & 0 \end{array} \right),$$

where $a = 2\sqrt{2}G_F n_e E$ and $U$ is given by eq.\textsuperscript{[2]} This is diagonalized by a mixing matrix $U_m$ as $M_m^2 = U_m \text{diag}(\tilde{m}_1^2, \tilde{m}_2^2, \tilde{m}_3^2) U_m^\dagger$. It is written with a real unitary (orthogonal) matrix $\tilde{U}$ as

$$U_m = \exp(i\psi\lambda_7)\Gamma\tilde{U}. \quad (27)$$

With arguments analogous to §2.1 we have the T violation effect,

$$P(\nu_\alpha \rightarrow \nu_\beta) - P(\nu_\beta \rightarrow \nu_\alpha) = 4 J_m f_m, \quad (28)$$

where

$$J_m = -\text{Im} U_{m\beta 1} U_{m\alpha 2}^* U_{m\alpha 1}^* U_{m\alpha 2} = \sin\psi\cos\psi \tilde{U}_{11} \tilde{U}_{12} \tilde{U}_{13} \sin\delta, \quad (29)$$

$$f_m = \sin\frac{\tilde{m}_2^2 - \tilde{m}_1^2}{2E} L + \sin\frac{\tilde{m}_3^2 - \tilde{m}_2^2}{2E} L + \sin\frac{\tilde{m}_1^2 - \tilde{m}_3^2}{2E} L. \quad (30)$$

We get

$$D_m \equiv \text{diag}(\tilde{m}_1^2, \tilde{m}_2^2, \tilde{m}_3^2) = U_m^\dagger M_m^2 U_m = \tilde{U}^\dagger \left( U_\phi U_\omega \left( \begin{array}{cc} 0 & \delta m_{21}^2 \\ \delta m_{31}^2 & \delta m_{31}^2 \end{array} \right) U_\omega^T U_\phi^T + \left( \begin{array}{cc} a & 0 \\ 0 & 0 \end{array} \right) \right) \tilde{U}$$

$$= \tilde{U}^\dagger \left( \begin{array}{cc} a + \delta m_{31}^2 \sin^2 \phi & 0 \\ \delta m_{31}^2 \cos \phi \sin \phi & 0 \end{array} \right) + \delta m_{21}^2 U_\phi U_\omega \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right) U_\omega^T U_\phi^T \right) \tilde{U}, \quad (31)$$
where \( U_\phi = \exp(i\phi \lambda_5) \) and \( U_\omega = \exp(i\omega \lambda_2) \).

An exact result for \( U_m \) and \( D_m \) is given in [30], though their result is rather complicated. Here we show a simple expression for \( U_m \) and \( D_m \) in the case \( \delta m_{21}^2 \ll a, \delta m_{31}^2 \). We derive \( U_m \) and \( D_m \) in this case using perturbation with respect to small \( \delta m_{21}^2 \).

First we decompose \( \bar{U} = U_0 V \) and diagonalize by \( U_0 \) the first term of the parenthesis \{ \} of eq.31, the eigenvalues of which we denote by \( \Lambda \)'s. We find

\[
U_0 = \exp(i\phi' \lambda_5) \text{ with } \tan 2\phi' = \frac{\delta m_{31}^2 \sin 2\phi}{\delta m_{31}^2 \cos 2\phi - a},
\]

and

\[
\begin{align*}
\Lambda_1 &= \frac{(a+\delta m_{31}^2)-\sqrt{(a+\delta m_{31}^2)^2-4a\delta m_{31}^2 \cos^2 \phi}}{2}, \\
\Lambda_2 &= 0, \\
\Lambda_3 &= \frac{(a+\delta m_{31}^2)+\sqrt{(a+\delta m_{31}^2)^2-4a\delta m_{31}^2 \cos^2 \phi}}{2}.
\end{align*}
\]

We have

\[
D_m = V^\dagger \begin{pmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_3 \end{pmatrix} + \delta m_{21}^2 U_{\phi' - \phi'} U_\omega \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} U_\omega^T U_{\phi' - \phi'}^T \}
\equiv V^\dagger \{ \text{diag}(\Lambda_1, \Lambda_2, \Lambda_3) + \delta m_{21}^2 H \} V.
\]

Next we diagonalize the whole \( M_m^2 \) by \( V \) with perturbation with respect to small \( \delta m_{21}^2 \).

At the zeroth order of \( \delta m_{21}^2 \), we have \( \tilde{m}_i^2 = \Lambda_i, \ V_{ij} = \delta_{ij}, \) and \( \bar{U} = U_0 \) which gives \( \bar{U}_{12} = (U_0)_{12} = 0 \) and hence \( J_m = 0 \) (see eq.29).

At the first order of perturbation, we have

\[
\tilde{m}_i^2 = \Lambda_i + \delta m_{21}^2 H_{ii},
\]

\[
V_{ij} = \begin{cases} 1 & \text{for } i = j \\ \delta m_{21}^2 \delta_{ii} / \Lambda_i - \Lambda_i & \text{for } i \neq j \end{cases},
\]

and with eq.29

\[
J_m = \frac{(a+\delta m_{31}^2)^2 - 4\delta m_{31}^2 a \cos^2 \phi}{1/2} \frac{\sin \omega \cos \omega \sin \psi \cos \psi \sin \phi \sin \delta.}
\]

### 4.2 Most likely case: \( \delta m_{21}^2 \ll a \ll \delta m_{31}^2 \)

It seems most likely to be realized that \( \delta m_{21}^2 \ll a \ll \delta m_{31}^2 \) as is discussed in §3.2. Here we study this case in detail. Since \( J_m \) is \( O(\delta m_{21}^2) \) we neglect \( O(\delta m_{21}^2) \) in estimating \( f_m \).

We also neglect \( O(a^2) \) since \( a/\delta m_{31}^2 \ll 1 \).

Then we have the effective masses

\[
\tilde{m}_1^2 \simeq \Lambda_1 \simeq a \cos^2 \phi, \\
\tilde{m}_2^2 \simeq \Lambda_2 \simeq 0, \\
\tilde{m}_3^2 \simeq \Lambda_3 \simeq \delta m_{31}^2 + a \sin^2 \phi.
\]
and “mass difference ratio”

\[ \epsilon_m = \frac{\tilde{m}_2^2 - \tilde{m}_1^2}{\tilde{m}_3^2 - \tilde{m}_2^2} \approx - \frac{a \cos^2 \phi}{\delta m_{31}^2}. \]  

(39)

Note that \(|\epsilon_m| \ll 1\).

We find

\[ J_m \sim -\frac{\delta m_{21}^2}{a} \sin \omega \cos \omega \sin \psi \cos \psi \sin \phi \sin \delta, \]  

(40)

and

\[ J_m \epsilon_m = J\epsilon. \]  

(41)

Using the argument similar to that used to derive eq.21, we obtain the T violation effect

\[ <P(\nu_\alpha \to \nu_\beta) - P(\nu_\beta \to \nu_\alpha) >_{20\%} = J_m \epsilon_m \times \begin{pmatrix} 25.9 \\ 56.0 \\ 62.4 \end{pmatrix} = J\epsilon \times \begin{pmatrix} 25.9 \\ 56.0 \\ 62.4 \end{pmatrix}, \]  

(42)

at peaks, where we choose the mean neutrino energy \(E\) to satisfy (see Table 1)

\[ \Delta_{31} = \frac{\delta m_{31}^2 L}{2E} = 3.67, 9.63, 15.8 \ldots \]  

(43)

According to the analysis by Fogli et al [1], \(J/\sin \delta \sim 0.06\) and \(\epsilon \sim 10^{-2}\) are allowed\(^4\) for example. Then

\[ <P(\nu_\alpha \to \nu_\beta) - P(\nu_\beta \to \nu_\alpha) >_{20\%} = \left( \frac{J}{\sin \delta} \right) \left( \frac{\epsilon}{10^{-2}} \right) \sin \delta \times \begin{pmatrix} 0.015 \\ 0.033 \\ 0.037 \end{pmatrix}. \]  

(44)

5 Summary

We have examined the CP and T violation in the neutrino oscillation, and analysed how large the violation can be by taking account of the constraints of the neutrino experiments.

In case of the comparable mass differences of \(\delta m_{21}^2, \delta m_{31}^2\) and \(\delta m_{32}^2\) in the range \(10^{-3}\) to \(10^{-2}\) eV\(^2\), which is consistent with the analysis of the atmospheric neutrino anomalies, it is found that there is a possibility that the CP violation effect is large enough to be observed by 100 ~ 1000 km base line experiments if the CP violating parameter \(\sin \delta\) is sufficiently large.

\(^4\) Here \(\sin \omega \sim 1/2, \sin \psi \sim 1/\sqrt{2}\) and \(\sin \phi = \sqrt{0.1}\).
In case that $\delta m^2_{21}$ is much smaller than the matter parameter “a” and $\delta m^2_{31}$, which is favored both by the solar and atmospheric neutrino anomalies, we have derived a simple formula for the T violation effect. We note that the probability of CP or T violation effect should vanish for $\delta m^2_{21} \to 0$, and therefore be proportional to $\delta m^2_{21}/\delta m^2_{31}$, $\delta m^2_{21}/(E/L)$ or $\delta m^2_{21}/a$ by the dimensional analysis. Our calculation confirms this expectation. If the solar and atmospheric neutrino anomalies are both attributed to the neutrino oscillation, the CP violation test is found difficult since matter effect is larger than the pure CP violation effect. How to extract the matter effect in such a case will be discussed in a separate paper[29].

In conclusion the long base line neutrino oscillation experiments are very important and desirable to study not only neutrino masses and mixings but the CP or T violation in the lepton sector and there is some possibility to find such effect explicitly.

We finally express our thanks to Prof. K. Nishikawa for valuable discussions and communications.
