TRY plant trait database – enhanced coverage and open access

Abstract

Plant traits—the morphological, anatomical, physiological, biochemical and phenological characteristics of plants—determine how plants respond to environmental factors, affect other trophic levels, and influence ecosystem properties and their benefits and detriments to people. Plant trait data thus represent the basis for a vast area of research spanning from evolutionary biology, community and functional ecology, to biodiversity conservation, ecosystem and landscape management, restoration, biogeography and earth system modelling. Since its foundation in 2007, the TRY database of plant traits has grown continuously. It now provides unprecedented data coverage under an open access data policy and is the main plant trait database used by the research community worldwide. Increasingly, the TRY database also supports new frontiers of trait-based plant research, including the identification of data gaps and the subsequent mobilization or measurement of new data. To support this development, in this article we evaluate the extent of the trait data compiled in TRY and analyse emerging patterns of data coverage and representativeness. Best species coverage is achieved for categorical traits—almost complete coverage for 'plant growth form'. However, most traits relevant for ecology and vegetation modelling are characterized by continuous intraspecific variation and trait–environmental relationships. These traits have to be measured on individual plants in their respective environment. Despite unprecedented data coverage, we observe a humbling lack of completeness and representativeness of these continuous traits in many aspects. We, therefore, conclude that reducing data gaps and biases in the TRY database remains a key challenge and requires a coordinated approach to data mobilization and trait measurements. This can only be achieved in collaboration with other initiatives.

1 | INTRODUCTION

Plant traits—the morphological, anatomical, physiological, biochemical and phenological characteristics of plants measurable at the individual plant level (Violle et al., 2007)—reflect the outcome of evolutionary and community assembly processes responding to abiotic and biotic environmental constraints (Valladares, Gianoli, & Gomez, 2007). Traits and trait syndromes (recurrent coordinated expressions of multiple traits) determine how plants perform and respond to environmental factors (Grime, 1974; Wright et al., 2017), affect other trophic levels (Lavorel et al., 2013; Loranger et al., 2012, 2013), and provide a link from species richness to functional diversity, which influences ecosystem properties and derived benefits and detriments to people (Aerts & Chapin, 2000; Díaz et al., 2004, 2007; Garnier & Navas, 2012; Grime, 2001, 2006; Lavorel et al., 2015; Lavorel & Garnier, 2002). In the context of the Global Earth Observation Biodiversity Observation Network (GEO BON) species traits are considered an Essential Biodiversity Variable to inform policy about biodiversity change (Kissling et al., 2018; Pereira et al., 2013). A focus on traits and trait syndromes, therefore, provides a crucial basis for quantitative and predictive ecology, ecologically informed landscape conservation and the global change science-policy interface (Díaz et al., 2016; McGill, Enquist, Weiher, & Westoby, 2006; Westoby & Wright, 2006). To fully realize this potential, plant trait data not only need to be available and accessible in appropriate quantity and quality but also representative for the scales of inference and research questions (König et al., 2019). Here we analyse where the TRY plant trait database stands with respect to coverage and representativeness after 12 years of operation. We further review the mechanisms and emergent dynamics helping to increase both.

1.1 | A global database of plant traits—A brief history

Before the foundation of TRY in 2007, several research groups had already developed major plant trait databases with remarkable success, e.g. the Ecological Flora of the British Islands (Fitter & Peat, 1994), the Seed Information Database (Royal Botanical Gardens KEW, 2008), BIOPOP (Poschlod, Kleyer, Jackel, Dannemann, & Tackenberg, 2003), GLOPNET (Wright et al., 2004), BioFlor (Klotz, Kühn, & Durka, 2002, 2017), LEDA (Kleyer et al., 2008), BROT (Paula et al., 2009), USDA PLANTSdata (Green, 2009) and BRIDGE (Baraloto, Timothy Paine, Patino, et al., 2010). However, these databases were either focused on particular regions (BioFlor, LEDA, BIOPOP, BROT, USDA Plants, Ecological Flora of the British Islands, BRIDGE) or specific traits (GLOPNET, SID). A ‘database of databases’ was in discussion for some time, but it had been impossible to secure long-term funding for such a project. Finally, at a joint workshop of the International Geosphere-Biosphere Program (IGBP) and DIVERSITAS, the TRY database (TRY—not an acronym, rather a statement of sentiment; https://www.try-db.org; Kattge et al., 2011) was proposed with the explicit assignment to improve the availability and accessibility of plant trait data for ecology and earth system sciences. The Max Planck Institute for Biogeochemistry (MPI-BGC) offered to host the database and the different groups joined forces for this community-driven program. Two factors were key to the success of TRY: the support and trust of leaders in the field of functional plant ecology submitting large databases and the long-term funding by the Max Planck Society, the MPI-BGC and the German Centre for Integrative Biodiversity Research (iDiv) Halle-Jena-Leipzig, which has enabled the continuous development of the TRY database.

At the time of the foundation of TRY, data sharing was not yet a common practice in ecology (Kattge et al., 2011; Reichman, Jones, & Schildhauer, 2011). This was an important obstacle for scientific progress. The first important step of the initiative was, therefore, to jointly develop a data sharing policy. This was based on permission of data set owners and a ‘give-and-take’ system: to keep the TRY database growing, the right to request data was coupled to data contribution. Exceptions were data requests for vegetation modelling projects, as modellers typically do not own plant trait data. At an open workshop in 2013, the members decided to offer the opportunity to make data publicly available and trait data contribution was no longer a requirement for data access. In 2014, this decision was implemented in the TRY Data Portal and was immediately followed by an ‘explosion’ of the number of data requests (Figure 1a): TRY
started to serve more than 1,000 requests per year, so that as of July 2019, about 700 million trait records accompanied by 3 billion ancillary data have been released for 7,000 requests, submitted by more than 5,000 registered users. Since 2019, the TRY database is open access under a Creative Commons Attribution license (CC BY 4.0, https://creativecommons.org/licenses/by/4.0): anyone can use and redistribute data received via TRY under the only condition of appropriate citation of the TRY database and the references of contributing data sets. Restriction of data access now is the exception and limited to 2(+2) years, after which the data sets become public.

Since 2014, the TRY Data Portal (https://www.try-db.org/TryWeb/dp.php) has become the central access point of the TRY database: the portal organizes data uploads, searches and requests, and enables interaction between data contributors, management and users. The portal provides an account for each data set custodian (the individual who directly contributed the data set), which provides precise bookkeeping about the use of his or her trait data via TRY. The TRY Data Portal also provides a link to the TRY File Archive (https://www.try-db.org/TryWeb/Data.php), which offers climate and soil data for TRY measurement sites, standardized

**FIGURE 2** Cluster analysis of keywords from peer-reviewed publications using plant trait data via TRY. The size of the circles and letters indicates the frequency of the keywords, colours indicate the eight clusters around the central keywords (from largest to smallest cluster): biodiversity (red), climate change (dark green), plant traits (dark blue), functional diversity (light green), carbon cycle (violet), community (light blue), vegetation (orange) and environmental filtering (brown). The analysis is based on 190 publications with DOIs compiled by ISI Web of Science (https://clarivate.com/products/web-of-science). The analysis was performed with VOSviewer version 1.6.11 (https://www.vosviewer.com) using the default settings and only minor editing of selected terms. The clustering technique used by VOSviewer is discussed by Waltman, van Eck, and Noyons (2010). Due to limited space not all central keywords of small clusters are displayed. Material to display the results in detail using the VOSviewer software is provided in the Supporting Information.
categorical traits relevant to attribute species to plant functional types (PFTs), and provides the opportunity to publish plant trait data sets and receive a DOI.

Trait data via TRY contributed to at least 250 scientific applications and publications (Figure 1a), among these 202 peer-reviewed publications in 83 different scientific journals, covering a broad range of topics, from ‘Landscape and Urban planning’ to ‘Geoscientific Model Development’. Twenty publications were directly related to vegetation model development, while 230 were empirical studies. A cluster analysis of keywords from the peer-reviewed publications shows eight clusters around the central keywords biodiversity, climate change, plant traits, functional diversity, carbon cycle, community, vegetation and environmental filtering (Figure 2). Citations of publications using trait data via TRY have increased exponentially, leading to about 10,000 citations and an h-factor of 46 for the TRY database (Figure 1b).

During 12 years of development, versions 1–5 of the TRY database have been released with an increasing number of contributed data sets and trait records (Tables 1 and 2; Figure 1a). Currently, TRY is working on version 6. As of July 2019, the TRY database comprises 588 data sets from 765 data contributors (Table A1). The dynamics of the number of data sets in TRY indicates an increasing success of calls to the scientific community for data contribution in 2007, 2013 and 2019. When the manuscript was submitted, data contributions responding to the call in 2019 were not yet fully integrated into the TRY database. Therefore all analyses presented in this paper are based on versions 1–5 of the TRY database (Table 1). TRY version 5, released on 26 March 2019, contains 387 data sets providing 11.8 million trait records, accompanied by 35 million ancillary data, for 2,091 traits and 280,000 plant taxa, mostly at the species level (Table 2). Data coverage is still driven by a few large (often integrated) databases, but increasingly small data sets (mostly primary data) contribute to the overall coverage (Figure 3a). Plant trait data in TRY can be traced to >10,000 original references. This highlights the breadth of data integrated in the TRY database and its nature as database of databases, a ‘second generation of data pooling’ (M. Westoby, personal communication, August 24, 2009).

We now observe a tendency that new trait-based research is increasingly planned against the background of the TRY database. Coverage and availability of trait data in TRY stimulate trait-based research, which then often leads to the identification of unexpected data gaps. This motivates data mobilization and/or new measurements, which improve the availability of plant trait data for the research community, and—if contributed to TRY—help the database grow. Examples for such a ‘feed-forward data integration loop’ are provided in Box 1.

To support this process, in this article, we take stock of the data compiled in the TRY database and present emerging patterns of data coverage and representativeness with a focus on the identification of principal and systematic gaps. Finally, we discuss ways forward and the potential future role of the TRY initiative for the research community.

### 2 | MATERIALS AND METHODS

#### 2.1 | Plant trait data in the TRY database

Plant traits can be classified as categorical (qualitative and ordinal) or quantitative (continuous) traits (Kattge et al., 2011). Some traits are rather stable within species (mostly categorical traits), and some of these can be systematically compiled from species checklists and floras (e.g. Weigelt, König, & Kreft, 2019).
However, most traits relevant to ecology and earth system sciences are characterized by intraspecific variability and trait–environment relationships (mostly quantitative traits). Both kinds of traits are compiled in the TRY database, but with a focus on continuous traits. These traits have to be measured on individual plants in their particular environmental context. Each such trait measurement has high information content as it captures the specific response of a given genome to the prevailing environmental conditions. The collection of these quantitative traits and their essential environmental covariates is important but often tedious and expensive: researchers need to travel to the objects of interest—often to remote places—or they need to develop experiments creating specific environmental conditions. While trait measurements themselves may be relatively simple, the selection of the adequate entity (e.g., a representative plant in a community, or a representative leaf on a tree) and obtaining the relevant ancillary data (taxonomic identification, soil and climate properties, disturbance history, etc.) may require sophisticated instruments and a high degree of expertise and experience. Besides, these data are most often individual measurements with a low level of automation. This not only limits the number of measurements but also causes a high risk of errors, which need to be corrected a posteriori, requiring substantial human work. The
integration of these data from different sources into a consistent data set requires a carefully designed workflow with sufficient data quality assurance (see Box 2: TRY data integration workflow).

These measurements of quantitative traits are single sampling events for particular individuals at certain locations and times, which preserve relevant information on intraspecific variation and provide the necessary detail to address questions at the level of populations or communities. Within individual field campaigns or experiments, researchers often aim to measure complete sets of these data: all traits of interest for all individuals or species in the analyses. However, across studies and data sets and at large scales, the coverage of these data shows major gaps, which provide major challenges concerning data completeness and representativeness (König et al., 2019).

3 | RESULTS

3.1 | Data coverage

Compared to TRY database version 1 and the state reported in Kattge et al. (2011), TRY version 5 has substantially grown with respect to the number of trait records, traits, species, entities, georeferenced measurement sites and ancillary data (Table 2).

3.2 | Trait records and entities

The numbers of trait records (individual trait measurements) and entities (individual plants or plant organs on which the measurements have been taken) increased by a factor of about 6 for trait
The number of traits has grown steadily from TRY version 1 to 5, apart from a steep step from TRY version 3 to 4 (Table 2). This step was caused by the contribution of the FRED database, which added about 700 new traits for roots. Data coverage across traits is characterized by long-tail distributions: a small number of traits is well covered by records and species, while the majority of traits has only very low coverage of records and species (Figure 3). However, the number of continuous traits with more than 1,000 records (which are subject to intense data quality assurance during integration) has increased from about 200 in TRY version 1 to 600 in TRY version 5 (Figure 3b). The number of traits with data for more than 100 species has increased from 300 to 700 (Figure 3c). In parallel, the number of records per trait and species (‘intraspécific retakes’) has increased from almost zero traits with on average more than 10 records per
trait–species combination in TRY version 1 to more than 500 in TRY version 5 (Figure 3f).

The traits with the best species coverage in TRY version 5 are mostly categorical (Table 3). The categorical traits used for the version 5 (Figure 3f).

Table 3: Traits with best species coverage. The 30 traits covering the highest number of species in the TRY database version 5 and the number of species represented for these traits in TRY version 1. Data type: cat = categorical; con = continuous. Sorted by the number of species in TRY 5.

| Trait name                        | Data type | Number of species | TRY 1 | TRY 5 |
|-----------------------------------|-----------|-------------------|-------|-------|
| Plant growth form                 | cat       | 31,327            | 263,357|

\(^a\)In case of compound leaves: leaflet, undefined if petiole is included or excluded.

\(^b\)Undefined if petiole is included or excluded.

classification of PFTs—plant woodiness, plant growth form, leaf type (broadleaved vs. needle-leaved), leaf phenology type (deciduous vs. evergreen), leaf photosynthesis pathway (C3, C4, CAM)—are still among the best covered. However, the number of species characterized for each of these traits has substantially increased from TRY version 1 to 5, most significantly for plant growth form from 31,327 to 263,357 species, supported by the contribution from the GIFT database (Weigelt, König, & Kreft, 2019).

The quantitative traits with the highest species coverage are still the six traits which were already prominent in TRY version 1 and involved in the analysis of the global spectrum of plant form and function (Díaz et al., 2016): plant height, seed mass, leaf area, leaf area per dry mass, leaf nitrogen content per dry mass and stem specific density (SSD). However, in general, the coverage of continuous traits already present in TRY 1 has substantially improved. This facilitates a more robust characterization of frequency distributions (Figure 4). In most cases, the range of observed trait values did not change much from TRY version 1 to 5, but the shapes of frequency distributions became more regular and pronounced, especially for multimodal frequency distributions like plant height and leaf Δ13C. Noteworthy, the examples in Figure 4 lack several kinds of traits because they are missing relevant numbers of trait records, like roots (only one trait), flowers and dead plant material (litter), secondary metabolites or data related to trophic interactions.

The 30 traits that were most often requested (Table 4) are dominated by continuous traits related to the global spectrum of plant form and function (Díaz et al., 2016), the leaf economics spectrum (Wright et al., 2004) and rooting depth. Only seven categorical traits are among these 30 traits. This indicates a switch between well covered—categorical—traits (Table 3) and most frequently requested—continuous—traits (Table 4). The first five most documented traits are categorical whereas among the 10 most requested traits, only one is categorical. However, within continuous traits, there is, in general, a good match between traits characterized for most species and traits most often requested. To some extent this may be influenced by the amount of available data for the individual traits. However, a noteworthy exception is rooting depth, as 10% of requests ask for this trait, while it is ‘only’ covered for 3,886 species, mostly contributed via the Global Dataset of Maximum Rooting Depth (Fan, Miguez-Macho, Jobbágy, Jackson, & Otero-Casal, 2017). This mismatch indicates a demand for more data on the most relevant below-ground traits.

3.4 | Species

From TRY version 1 to 4, the number of species increased slowly, but almost doubled to version 5 due to the contribution of plant growth form data from the GIFT database, which added about 100,000 new species. As in the case of traits, the data coverage for species is characterized by long-tail distributions: few species are covered well by measurements and traits, while the majority...
**FIGURE 4** Frequency distributions of observations for 15 ecologically relevant and well sampled continuous traits from different plant organs. Grey: TRY version 1; white: TRY version 5. (a) Plant height, (b) Seed mass, (c) SSD: stem dry mass per stem fresh volume (stem specific density), (d) Leaf area, (e) SLA: leaf area per leaf dry mass (specific leaf area), (f) Leaf N mass: leaf nitrogen content per leaf dry mass (leaf nitrogen concentration), (g) LDMC: leaf dry mass per leaf fresh mass (leaf dry matter content), (h) Leaf P mass: leaf phosphorus content per leaf dry mass, (i) Leaf C mass: leaf carbon content per leaf dry mass, (j) Leaf N area: leaf nitrogen content per leaf area, (k) Leaf P area: leaf phosphorus content per leaf area, (l) Leaf CN: leaf carbon content per leaf nitrogen content, (m) Leaf 13C: leaf 13C carbon isotope signature, leaf Δ13C, (n) Leaf 15N: leaf 15N nitrogen isotope signature, (o) SRL: root length per root dry mass (specific root length).
of species has only very low data coverage (Figure 3d-f). The species characterized by the most traits tend to be northern temperate trees or globally distributed pasture species (Table 5). Out of the top 30 species with the best trait coverage, 27 (90%) originate in Central or Northern Europe.

### Table 5: Species with best trait coverage

| Species | Plant growth form | TRY 1 | TRY 5 |
|---------|------------------|-------|-------|
| Pinus sylvestris | Tree | 264 | 569 |
| Fagus sylvatica | Tree | 237 | 517 |
| Picea abies | Tree | 252 | 475 |
| Quercus robur | Tree | 194 | 435 |
| Acer saccharum | Tree | 139 | 430 |
| Betula pendula | Tree | 265 | 429 |
| Achillea millefolium | Herb | 209 | 403 |
| Acer pseudoplatanus | Tree | 186 | 397 |
| Trifolium pratense | Herb | 181 | 395 |
| Quercus rubra | Tree | 190 | 388 |
| Dactylis glomerata | Herb | 193 | 387 |
| Plantago lanceolata | Herb | 156 | 386 |
| Vaccinium vitis-idaea | Shrub | 189 | 382 |
| Trifolium repens | Herb | 173 | 380 |
| Fraxinus excelsior | Tree | 196 | 378 |
| Acer platanoides | Tree | 186 | 378 |
| Quercus petraea | Tree | 194 | 368 |
| Poa pratensis | Herb | 195 | 366 |
| Holcus lanatus | Herb | 178 | 364 |
| Tilia cordata | Tree | 153 | 362 |
| Calluna vulgaris | Shrub | 190 | 360 |
| Lotus corniculatus | Herb | 153 | 360 |
| Pseudotsuga menziesii | Tree | 141 | 356 |
| Medicago lupulina | Herb | 145 | 351 |
| Festuca rubra | Herb | 175 | 347 |
| Sorbus aucuparia | Tree | 197 | 335 |
| Phleum pratense | Herb | 179 | 335 |
| Quercus ilex | Tree | 195 | 333 |
| Betula papyrifera | Tree | 126 | 332 |
| Vaccinium uliginosum | Shrub | 169 | 330 |

### Table 4: Most often requested traits

| Trait | Data type | Number of requests |
|-------|-----------|--------------------|
| Leaf area per leaf dry mass (specific leaf area or 1/LMA) | con | 2,977 (41%) |
| Plant height vegetative | con | 2,159 (29%) |
| Leaf nitrogen (N) content per leaf dry mass | con | 1,938 (26%) |
| Leaf area | con | 1,676 (23%) |

### 3.5 Entity × trait and species × trait matrices

The trait data in the TRY database can be represented by two two-dimensional matrices: the entity × trait matrix, with entities in rows and traits in columns; and the species × trait matrix, with species in rows and traits in columns. Both matrices are characterized as large but sparse: high numbers of entities, species and traits in TRY make the two matrices large, but many cells in the matrices are empty. From TRY version 1 to 5 the size of the matrices has grown by a factor of 15, but at the same time the number of trait records to fill
the cells increased only by a factor of about 5 and thus the matrices became even sparser: the fractional coverage decreased from 0.4% to 0.1% (entity × trait) and 1.4% to 0.4% (species × trait; Figure 5a). This sparsity together with the observed long-tail distributions has consequences, especially for multivariate analyses. Given that on average only two to three traits of the 2,091 traits in TRY version 5 are measured on an individual plant (entity), a multivariate analysis based on individuals is indeed practically impossible, as mentioned by Shan et al. (2012). Even after aggregation at the species level, the decline of the number of species with complete trait coverage when adding a new trait, for example for multivariate analysis, is surprisingly high (Figure 5b). Additionally, the final number of species represented in the analysis is determined by the trait with the lowest species coverage. Therefore multivariate analyses with more than about six traits are still very much limited by the number of species. The same applies when species have to be classified by several categorical traits, like for example in the context of PFTs.

3.6 Ancillary data

The numbers of ancillary data, geo-referenced trait records and trait records with measurement date increased by a factor of almost 10 from TRY version 1 to TRY version 5 (Table 2). The ratio of ancillary data to trait records, therefore, increased from TRY version 1 to 5 from 2:1 to 3:1 and the fraction of geo-referenced trait records from about 33% to 42% (Table 2). The number of geo-referenced trait records with information on measurement date that could be standardized to year, month and day increased from 290,000 in TRY version 1 (15% of all trait records) to 2.5 million records in TRY version 5 (20%). The increasing ratio of ancillary data to trait records indicates growing awareness for the relevance of environmental conditions during plant growth and trait measurements. In this context, geo-references (and date) are crucial, as they allow trait records to be related to information on climate, soil or biome type from external sources.

The geographic coverage of trait measurements has substantially improved from TRY version 1 (8,276 measurement sites representing 1,260 1° × 1° grid-cells) to TRY version 5 (20,953 sites representing

![Figure 5](image-url)
Europe still has the highest density of measurement sites, but TRY version 5 also provides good coverage for the United States and China. The number of measurement sites has substantially improved for several other regions as well, for example Central America, Russia, Asia and parts of central Africa. However, there are still obvious gaps in boreal regions (Canada, East Russia) and some parts of the tropics and subtropics, particularly in Africa (Figure 6).

### 3.7 Data completeness and representativeness

To progress from a description of data coverage towards an analysis of representativeness, we need a baseline for comparison. At the global scale, this information has been lacking. Reference data sets have become available only recently for plant growth form (Weigelt, König, & Kreft, 2019) and phylogeny (Smith & Brown, 2018) representing about 260,000 and 356,000 of the 400,000 extant species. Together with estimations for the global distribution of plant species richness (Kier et al., 2005), it seems now possible and timely to explicitly address representativeness of plant trait data in the TRY database along five key dimensions: (a) Are trait data in TRY well distributed among plant parts? (b) Are the species in TRY and for individual traits representative for global plant growth forms and functional types? (c) Are the species in TRY and for individual traits representative according to phylogeny? (d) Does the geographic distribution of species richness in TRY represent the estimated pattern of global species richness? (e) Is data coverage sufficient to represent intraspecific variation?

### 3.8 Distribution of trait records among plant parts

Trait records in the TRY database are very unequally distributed among different plant parts (Figure 7): leaves and the whole plant are well represented; shoot and reproductive organs are moderately represented; roots and dead material (morphological and chemical feature of litter and coarse woody debris, but also decomposition rates) are not well represented. Within reproductive organs, seeds are better represented than floral traits, mostly due to contributions from the Seed Information Database. The skewed distribution of
trait records to the different parts of the plants has only changed little from TRY version 1 to 5. However, the fraction of records for root traits has substantially increased (from 0.7% to 2.0%), due to the contribution of the FRED database.

### 3.9 Plant growth form and PFTs

The most basic approach to characterize functional groups of plant species and their impact on vegetation and ecosystem function is the plant growth form, with its simplest classification to herbs, shrubs and trees. We compare here the fraction of the different plant growth forms for trait measurements in TRY version 5 to a comprehensive baseline of plant growth form for >280,000 of the extant 400,000 species, which is currently developed in the context of the GIFT database project.

In GIFT, about 50% of species are currently assigned to herbs, 30% to trees and 20% to shrubs (Figure 8). This distribution is well reflected by the species in TRY (excluding data from the GIFT database). However, the six best covered continuous traits in TRY indicate that this distribution is very much trait dependent, with a bias towards trees versus herbs, while the fraction of shrubs is surprisingly constant and close to the fraction in the GIFT database (Figure 8). The overrepresentation of trees is most obvious for SSD, which is not surprising because SSD is a more general concept derived from wood density, a trait relevant for forestry, timber industry and estimates of forest vegetation biomass. However, the tendency of relatively more data for trees compared to other growth forms is also obvious for SLA, leaf nitrogen content per dry mass and leaf area, but opposite for root length per root dry mass (specific root length), which is frequently reported for herbs.

Apart from plant growth form, three additional categorical traits are relevant to determine PFTs commonly used in global vegetation models: leaf type (broadleaved vs. needle-leaved) and leaf phenology type (deciduous vs. evergreen) for tree species, and photosynthetic pathway (C3, C4, CAM) for herbaceous species. TRY provides leaf type and leaf phenology type, for about 10% of the estimated 130,000 tree species worldwide and photosynthetic pathway for about 6% of estimated 200,000 herb species.

### 3.10 Phylogeny

Smith and Brown (2018) published a series of broadly inclusive seed plant phylogenies. Here we chose the most comprehensive phylogeny (ALLMB), containing 356,305 taxa, as a baseline to visualize the coverage of TRY in a phylogenetic context. Taxa in ALLMB were cut to binomials and consolidated using the TNRS with TPL, GCC, ILDIS, TROPICOS and USDA as the taxonomic backbone (the same approach as for TRY). After consolidation, we could match the taxa in the phylogeny to 208,406 of the 279,875 taxa in TRY. Higher level taxonomy is based on Zanne et al. (2014).

Visually, the 208,000 species with data in TRY are well distributed across the 350,000 species represented in the phylogeny of seed plants (Figure 9). An ancestral state reconstruction (ASR) of species trait number confirms that the long-tail distribution previously seen at the species level also holds in a phylogenetic context: some clades are covered very well (bright colours), while most clades have lower data coverage (dark colours). The ASR additionally shows how deep in phylogeny data gaps are rooted. This indicates the potential for, and limits to, phylogenetically or taxonomically informed gap-filling (Schrodt et al., 2015). Examples of high-coverage clades are (parts of) the Pinales, Poales and Asterales. When looking at the six best-covered continuous traits individually, we find these too are well distributed across the phylogeny (Figure 9).

### 3.11 Geographic distribution of species richness

Jetz et al. (2016) reported a latitudinal gradient in disparities between plant species with regional measurements in TRY and estimated species richness, with the largest gap observed in the tropics, because these are especially rich in species. To address this in more detail, we...
here ask if the TRY database provides trait information for a relevant number of plant species in the different regions worldwide. To characterize regions in an ecologically meaningful way we adopt the ecoregions introduced by Olson et al. (2001), which are defined as relatively large units of land containing a distinct assemblage of natural communities and species, with boundaries that approximate the original extent of natural communities before major land-use change. The ecoregions are nested within biomes with biotic communities formed in response to a shared physical climate, most importantly temperature and rainfall. We compare the number of species, which have trait measurements in an ecoregion in TRY version 5 to species numbers per ecoregion estimated by Kier et al. (2005). This approach accounts to some extent for intraspecific trait variation, as it counts only species with at least one trait measurement in the given ecoregion.

The 839 ecoregions defined by Olson et al. (2001) are very different in size, from 6 km$^2$ (San Felix–San Ambrosio Islands temperate forests) to 4,639,920 km$^2$ (Sahara desert) with species numbers ranging from 0 (St. Peter and St. Paul rocks and the Maudlandia Antarctic desert) to 10,000 (Borneo lowland rain forests). The TRY database contains no trait measurements for 271 mostly small ecoregions and
up to 1,400 species for some ecoregions in Europe (Alps conifer and mixed forests) and tropical South America (Napo moist forests, Tapajos-Xingu moist forests). In general, high absolute numbers of species with trait measurements for ecoregions are found in Europe, East Asia, Oceania, Australia, tropical South America and the United States (Figure 10a). East Asia, Oceania and tropical South America are also the regions with the highest numbers of species per ecoregions estimated by Kier et al. (2005; Figure 10b).

**FIGURE 10** Geographic representativeness: (a) the number of species with at least one trait measurement in an ecoregion in TRY version 5; (b) number of species per ecoregion estimated by Kier et al. (2005); (c) fraction of species represented in TRY version 5 versus number of species per ecoregion estimated by Kier et al. (2005)
The best relative coverage in TRY (Figure 10c) is provided for the Marielandia Antarctic tundra (two species estimated and in TRY) and for a large ecoregion in Central Russia (West Siberian taiga, 900 species estimated, 885 in TRY). The species in the Russian ecoregion are measured at several sites relatively well distributed across the ecoregion, but dominated by just one trait, ‘mycorrhiza infection intensity’ contributed by the mycorrhizal intensity database (Akhmetzhanova et al., 2012). Some other ecoregions are also well covered with data for more than 50% of estimated species (Southeast Australia temperate savanna, Qaidam Basin semi-desert, Córdoba forests and mountain grasslands). Apart from these individual ecoregions spread across the world, large parts of Europe are well covered, with trait data for about 30% of the species number estimated by Kier et al. (2005). Some ecoregions in East Asia, Australia, tropical South America, the Sahara, and the United States are also well covered, providing data for about 20% of estimated species richness. Very low relative coverage (<2%) is observed for major parts of Canada, Africa, western Asia (Iran, Iraq, Pakistan, Afghanistan) and major parts of India.

3.12 | Intraspecific variation

Understanding and predicting intraspecific variation for a relevant number of traits and species is still in its infancy. Given that TRY is collecting trait measurements on individual plants, the TRY data set might be suited to address these questions. A precondition for such analyses is a minimum number of measurements on different individual plants at different sites per trait and species. To assess this issue, we plotted the number of species for which TRY version 5 contains a minimum number of individual measurements (Figure 11a) and the number of species for which TRY version 5 contains measurements from a minimum number of individual sites (Figure 11b) for the 15 best-covered continuous traits. By increasing the minimum number of individuals or sites, the number of species available for analysis decreases sharply (more than exponentially), whereas the exact slope is trait specific. The characterization of intraspecific variation in Kattge et al. (2011) relied on at least 20 individuals per species. Based on this criterion, TRY 5 provides information for hundreds to thousands of species for 14 out of the 15 traits (Figure 11a). Assuming a more realistic limit of 100 individuals per species, SLA and LDMC are sufficiently covered for about 300 species, and four other traits for more than 100 species. Assuming a minimum number of 200 individuals per species, four traits still allow for an analysis of 100 species, and nine traits allow for the analysis of intraspecific variation of more than 10 species. However, the numbers are more humbling if the environmental context is taken into account (Figure 11b). If we assume that trait records from a minimum number of 50 sites per species are necessary to represent intraspecific variation, four traits are sufficiently covered for about 100 species. If 100 sites are necessary, no trait is covered by data for more than 10 species.

4 | DISCUSSION

Plant trait data provide a wealth of information directly relevant in several scientific contexts, from conservation, ecology and evolution to earth system sciences. To fully realize this potential, the TRY
initiative was initiated in 2007 as a ‘database of databases’ and leading groups in the field of functional plant ecology joined forces for this community-driven program. The TRY database now provides an unprecedented number of consolidated plant trait data, which have become easily accessible at the TRY Data Portal under an open access data policy.

The TRY database is well accepted by the scientific community and has facilitated progress in different aspects of research, for example in global vegetation modelling from static PFTs to a more continuous representation of biodiversity (e.g. Peaucelle, Bellassen, Ciais, Peñuelas, & Viovy, 2016; Sakschewski et al., 2015, 2016; Verheijen et al., 2013, 2015), extending macroecology and biodiversity by functional aspects (e.g. Björkman, Myers-Smith, Elendorf, Normand, Rüger, et al., 2018; Brueelheide et al., 2018; Craven et al., 2018; Newbold et al., 2015), linking soil characteristics to vegetation attributes (e.g. Boeddinghaus et al., 2019; de Vries et al., 2012; Delgado-Baquerizo et al., 2018) and providing data for global maps of plant traits (e.g. Butler et al., 2017; Moreno-Martínez et al., 2018).

The central keywords of the cluster analysis in Figure 2 (biodiversity, climate change, plant traits, functional diversity, carbon cycle, community, vegetation and environmental filtering) seem to reflect the expectation that improved knowledge of plant functional diversity, mediated by plant traits, contributes to a better understanding of vegetation feedbacks to climate change and drivers and consequences of plant biodiversity loss.

Data coverage of the TRY database is characterized by four attributes: (a) long-tail distributions, (b) sparse matrices, (c) increasing number of ancillary data per trait record and (d) increasing geographic coverage. So far the size of the two sparse matrices (entity × trait and species × trait) has increased faster than the number of trait records to fill the matrices. Therefore the sparseness of the matrices has increased from TRY version 1 to 5 (the fractional coverage declined). Rather than converging in a small number of traits, the scientific community continues to measure a large, diverse number of traits, following equally diverse motivations.

However, given the number of species has a natural limit and assuming the number of traits will continue to grow, but more slowly, once the most obvious ones have been covered, we expect that the sparseness of the entity × trait matrix will become stable: new data adding new rows for entities, but not many new columns for traits. In comparison, the sparseness of the species × trait matrix should decline in the future; new data will mostly contribute to filling the matrix and increasing the number of species with data per trait. This reduced sparseness of the species × traits matrix will systematically improve the applicability of trait data for macroecology and earth system modelling and will facilitate multivariate analyses for an increasing number of traits. In parallel, the number of records per species–trait combination is increasing: between TRY 1 and 5 it already doubled and will further increase in the future. This increasing number of records per species–trait combination will improve data coverage for analyses of intraspecific trait variation and trait–environment relationships accounting for intraspecific variation. It is noteworthy that the matrix will not only become more complete, but the traits will increasingly be able to inform each other. The ‘usual suspects’ (i.e. the best covered continuous traits) might not be masters of all traits, but they surely will be very useful as baseline traits and provide a background against which other—maybe more influential—traits can be analysed for coverage, representativeness, orthogonality, etc.

### 4.1 Data completeness and representativeness

Despite unprecedented and continuously growing data coverage, we observe a humbling lack of completeness and representativeness in many aspects. The best species coverage is achieved for categorical traits relevant to determine PFTs commonly used in global vegetation models. For the traits ‘woodiness’ and ‘plant growth form’, even full species coverage is within reach, due to the contribution of data from the GIFT database. For the first time, this provides a global baseline for these traits, which are relevant to understand basic patterns of variation for several other traits (Díaz et al., 2016). With this baseline, future analyses will be able to address representativeness in addition to coverage, which will substantially contribute to better understand the global pattern of plant traits relevant for biodiversity and ecosystem function (König et al., 2019).

Most traits directly relevant for ecology and vegetation modelling are characterized by intraspecific variation and trait–environmental relationships; for these traits, completeness at the global scale is impossible and representativeness is challenging. We find that in the current version of the TRY database, these traits are biased against roots, floral traits and dead organic material, like litter or coarse woody debris. Plant growth forms and phylogeny are generally well represented, but there are significant biases for individual traits. The global distribution of species richness is only marginally reflected by trait measurements. We observe a general bias towards temperate biomes. In contrast to Jetz et al. (2016), the tropics do not stand out as especially underrepresented in our analysis; apart from Europe, all continents contain major regions that are very sparsely represented in TRY.

So far we addressed representativeness in a geographic context only based on species richness, the number of species observed in an ecoregion. To address representativeness in an ecologically more meaningful context, species identity and species abundance should be taken into account. Both aspects are relevant to community attributes and ecosystem function. There is ample evidence in the literature of the high influence, at the level of community structure and ecosystem dynamics, of species that represent a large proportion of the total local biomass (consisting of large individuals and/or large total cover). Such species have a particularly large impact on the community weighted mean trait value (Garnier et al., 2004), and particularly large individual trees may overrule remaining trees’ attributes (Ali et al., 2019). Initial evidence indicates that abundant species are better covered in TRY than rare species. Brueelheide et al. (2019) show that the 25% most dominant or most frequent species
compiled in the sPlot vegetation-plot database are better represented by trait data in the TRY database than species observed on the plots overall. We also checked this for the 227 hyperdominant species of the Amazonia tree flora identified by ter Steege et al. (2013). After the consolidation of species names via TNRS, all 227 hyperdominant species are present in the TRY database, with on average 69 traits per species, which is far above average (see Figure 3e). We therefore conclude that the coverage of trait data in TRY is biased towards the more abundant species in the respective ecoregions—which is reasonable and welcome for many kinds of analyses.

We have reported that intraspecific variation in space is increasingly well covered, but variation in time is hard to estimate. Nevertheless, intraspecific variation in time is relevant for several traits to characterize the seasonal variation of plant and ecosystem function (Xu & Baldocchi, 2003; Xu & Griffin, 2006) and long-term trends to inform policy about biodiversity change (Kissling et al., 2018). About half of the geo-referenced trait records have information on the sampling date that could be standardized to year, month and day, but systematic replicates over time (‘time series’) are rare (but see e.g. the ‘Photosynthesis Traits Database’; Xu & Baldocchi, 2003). In principle, ‘non-time series’ data allow detection of trait changes over time (Craine et al., 2018), but these analyses are very challenging, as most traits demonstrate stronger variation in geographic space along climate and soil gradients than over time. In addition, the variations of traits on different time scales (diurnal, seasonal, inter-annual variation and long-term trends) are superimposed and hard to disentangle. Apart from this, there is a need to collect and report repeated trait measurements from the same location or population to monitor biodiversity change and inform policy, for example in the context of GEO BON (Kissling et al., 2018).

4.2 | Ways forward

Figure 1 shows the most obvious way to mobilize additional trait data: the TRY initiative should regularly send calls for data contributions to the wider scientific community, that is the network of more than 6,000 researchers contributing and using trait data via TRY. These calls should be combined with regular publications of respective reference papers. This can be combined with (a) a systematic collection of data sets from public data repositories, which is becoming more effective with the general move by many journals to require that authors make their data open access; and (b) systematic extraction of trait data from the ecological literature, floras and herbarium specimens, which is a promising task, especially for its potential to open a window into the past. In parallel, TRY should further support the ‘feed-forward data integration loop’ outlined above: using trait data via TRY, identifying gaps, mobilizing and/or measuring new data, contributing additional data to TRY. This has proven very effective for focused data mobilization. If relevant gaps are detected, TRY can also send specific calls to the community.

As TRY has been designed as a community cyber-infrastructure based on the idea of incentive-driven data sharing (Kattge, Díaz, & Wirth, 2014), the collaboration and data exchange with other plant trait databases will continue to be the key to achieve a comprehensive representation of plant traits. TRY is, therefore, collaborating with many more recent trait database initiatives, such as, for example, FRED, GIFT, BIEN and the Tundra Trait Team, and since the early days of TRY–GLOPNET, LEDA, SID, BiolFlor, BIOPOP, BROTx, the Ecological Flora of the British Isles, eHALOPH, USDA PLANTSdata, BRIDGE and many others. Importantly, these collaborations need to provide mutual benefit. Based on these collaborations, the TRY database may serve as a central node for plant traits in an overarching network of trait databases, currently emerging in the context of the Open Traits Network (Gallagher et al., in press). Finally, new techniques and approaches are gradually becoming available, which may substantially change how plant trait data are collected: remote sensing, citizen sciences, microbiological and molecular screening, etc.

4.3 | Towards a third generation of plant trait data integration and sharing

We expect that the combination of (a) systematic involvement of the TRY network towards extraction and mobilization of legacy and recent trait data from public repositories, ecological literature, floras and herbaria, (b) facilitation of the ‘feed-forward data integration loop’ and (c) intensified collaboration of all plant trait-related initiatives, including new approaches and techniques, will be effective towards an increasingly comprehensive representation of plant traits. After the development of integrated databases focused on specific regions or topics, and the development of a ‘database of databases’, such a joined effort might be leading towards a third generation of plant trait data integration and sharing.

5 | CONCLUSION

TRY has received institutional support since 2007 and is still growing considerably in quantity and quality. While TRY may be considered a success and potentially a role model for database initiatives, it is important to realize that this development needed time and patience. It took until 2011 for the first TRY publications to appear because the early years of TRY were mostly devoted to the development of the database, organizing the community process towards a joint data sharing policy and building trust. This process involved initially dozens and later hundreds of scientist when it came to agree on moving towards open access. These dynamics do not fit into 3 year funding cycles as typically offered by national funding agencies. A key lesson of TRY is that the development of a database that is trusted by the community and accepted for its service and quality also needs the trust of the funders, that is long-term support, at the scale of decades rather than years. It also needs journals that are willing to accept long author lists and extended references lists to adequately acknowledge the original contributions that are the building blocks of communal databases.
ACKNOWLEDGEMENTS

We would like to thank Stephen Long for the invitation to contribute to the special issue celebrating the 25th anniversary of Global Change Biology and the Executive Editor Rachel Shekar for her extraordinary support and patience handling this manuscript. We also thank the publisher for excellent support. We thank the two anonymous reviewers for valuable suggestions, which helped to substantially improve the manuscript. The TRY database is hosted, developed and maintained at the Max Planck Institute for Biogeochemistry (MPI-BGC) in Jena, Germany, in collaboration with the German Centre for Integrative Biodiversity Research (iDiv) Halle-Jena-Leipzig. The TRY database receives additional funding by the Max Planck Society via the Max Planck Fellow Program for Christian Wirth. In addition, the TRY initiative has been supported by the International Programme of Biodiversity Science (DIVERSITAS), the International Geosphere-Biosphere Programme (IGBP), Future Earth, the French Foundation for Biodiversity Research (FRB), and GIS ‘Climat, Environnement et Société’ France. The TRY initiative is grateful for major support by Linda Maack and the IT Department at the MPI-BGC. We would like to thank all data contributors to TRY, who are not co-authors of this paper, that is Pierre Meerts, Jennifer Powers, Nina Koele, Henrik Balslev, John Briggs, Michael White and Robin Chazdon, V.O. thanks RSF (#19-14-00038). S.D. thanks CONICET, FONCyT and IAI. Finally, the TRY initiative is very grateful to all the numerous scientists not mentioned here measuring plant traits: without their work the TRY database would not exist.

CONFLICT OF INTEREST

All authors declare no conflict of interest.

AUTHOR CONTRIBUTION

Jens Kattge, Gerhard Bönisch, Sandra Diaz, Sandra Laveal, Iain Colin Prentice, Paul Leadley and Christian Wirth developed the concept and draft manuscript. Susanne Tautenhahn and Gisbert Werner contributed analyses and plots for Figures 9, 10 and 11. The other authors contributed plant trait data and/or supported data curation and analysis. All 729 authors contributed to writing.

### Table A1

Datasets contributed to the TRY plant trait database. Sorted by custodian surname. ID: Dataset ID in the TRY database, Name, Custodian, TRY version to which the dataset was submitted (in parentheses first submission), availability of the dataset (status 1.10.2019), reference.

| ID   | Dataset name                                                                 | Custodian          | Version | Availability | Reference                                                                 |
