Abstract We develop foundational tools for classifying the extreme valid functions for the $k$-dimensional infinite group problem. In particular, we present the general regular solution to Cauchy’s additive functional equation on restricted lower-dimensional convex domains. This provides a $k$-dimensional generalization of the so-called Interval Lemma, allowing us to deduce affine properties of the function from certain additivity relations. Next, we study the discrete geometry of additivity domains of piecewise linear functions, providing a framework for finite tests of minimality and extremality. We then give a theory of non-extremality certificates in the form of perturbation functions. We apply these tools in the context of minimal valid functions for the two-
dimensional infinite group problem that are piecewise linear on a standard triangulation of the plane, under a regularity condition called diagonal constrainedness. We show that the extremality of a minimal valid function is equivalent to the extremality of its restriction to a certain finite two-dimensional group problem. This gives an algorithm for testing the extremality of a given minimal valid function.

1 Introduction

Over 40 years ago, Gomory and Johnson introduced an elegant infinite-dimensional relaxation of integer linear optimization problems called the infinite group problem [17,18]. The motivation for studying it is the hope to find effective multi-row cutting plane procedures with better performance characteristics compared to the single-row cutting plane procedures in use today.

1.1 The group problem

Gomory’s group problem [16] is a central object in the study of strong cutting planes for integer linear optimization problems. One considers an abelian group $G$, written additively, and studies the set of functions $s : G \to \mathbb{R}$ satisfying the following constraints:

$$\sum_{r \in G} r s(r) \in f + S$$

$$s(r) \in \mathbb{Z}_+ \quad \text{for all } r \in G$$

$s$ has finite support,

where $S$ is a subgroup of $G$ and $f$ is a given element in $G \setminus S$; so $f + S$ is the coset containing the element $f$. We will be concerned with the so-called infinite group problem [17,18], where $G = \mathbb{R}^k$ is taken to be the group of real $k$-vectors under addition, and $S = \mathbb{Z}^k$ is the subgroup of the integer vectors. We are interested in studying the convex hull $R_f(G, S)$ of all functions satisfying the constraints in (1). Observe that $R_f(G, S)$ is a convex subset of the infinite-dimensional vector space $V$ of functions $s : G \to \mathbb{R}$ with finite support.

A main focus of the research in this area is to give a description of $R_f(\mathbb{R}, \mathbb{Z})$ as the intersection of halfspaces of $V$. This makes a very useful connection between $R_f(\mathbb{R}, \mathbb{Z})$ and traditional integer programming, both from a theoretical, as well as, practical point of view. This arises from the fact that important classes of cutting planes for general integer programs can be viewed as finite-dimensional restrictions of the linear inequalities used to describe $R_f(\mathbb{R}, \mathbb{Z})$.

1.2 Valid inequalities and valid functions

Any linear inequality in $V$ is given by $\sum_{r \in G} \pi(r) s(r) \geq \alpha$ where $\pi$ is a function $\pi : G \to \mathbb{R}$ and $\alpha \in \mathbb{R}$. The left-hand side of the inequality is a finite sum because $s$ has finite support. Such an inequality is called a valid inequality for $R_f(G, S)$ if $\sum_{r \in G} \pi(r) s(r) \geq \alpha$ for all $s \in R_f(G, S)$. It is customary to concentrate on valid inequalities with $\pi \geq 0$; then we can choose, after a scaling, $\alpha = 1$. Thus, we only focus on valid inequalities of the form $\sum_{r \in G} \pi(r) s(r) \geq 1$ with $\pi \geq 0$. Such functions $\pi$ will be termed valid functions for $R_f(G, S)$.

As pointed out in [8], the nonnegativity assumption in the definition of a valid function might seem artificial at first. Although there exist valid inequalities $\sum_{r \in \mathbb{R}} \pi(r) s(r) \geq \alpha$ for $R_f(\mathbb{R}, \mathbb{Z})$ such that $\pi(r) < 0$ for some $r \in \mathbb{R}$, it can be shown
that \( \pi \) must be nonnegative over all rational \( r \in \mathbb{Q} \). Since data in integer programs is usually rational, it is natural to focus on nonnegative valid functions.

### 1.3 Minimal functions

Gomory and Johnson [17,18] defined a hierarchy on the set of valid functions, capturing the strength of the corresponding valid inequalities, which we summarize now.

A valid function \( \pi \) for \( R_f(G, S) \) is said to be \textit{minimal} for \( R_f(G, S) \) if there is no valid function \( \pi' \neq \pi \) such that \( \pi'(r) \leq \pi(r) \) for all \( r \in G \). For every valid function \( \pi \) for \( R_f(G, S) \), there exists a minimal valid function \( \pi' \) such that \( \pi' \leq \pi \) (cf. [7]), and thus non-minimal valid functions are redundant in the description of \( R_f(G, S) \). Minimal functions for \( R_f(G, S) \) were characterized by Gomory for the case where \( S \) has finite index in \( G \) in [16], and later for \( R_f(\mathbb{R}, \mathbb{Z}) \) by Gomory and Johnson [17]. We state these results in a unified notation in the following theorem.

A function \( \pi : G \rightarrow \mathbb{R} \) is \textit{subadditive} if \( \pi(x + y) \leq \pi(x) + \pi(y) \) for all \( x, y \in G \). We say that \( \pi \) is \textit{symmetric} if \( \pi(x) + \pi(f - x) = 1 \) for all \( x \in G \).

**Theorem 1.1** (Gomory and Johnson [17]) Let \( \pi : G \rightarrow \mathbb{R} \) be a nonnegative function. Then \( \pi \) is a minimal valid function for \( R_f(G, S) \) if and only if \( \pi(z) = 0 \) for all \( z \in S \), \( \pi \) is subadditive, and \( \pi \) satisfies the symmetry condition. (The first two conditions imply that \( \pi \) is periodic modulo \( S \), that is, \( \pi(x) = \pi(x + z) \) for all \( z \in S \).)

**Remark 1.2** Note that this implies that one can view a minimal valid function \( \pi \) as a function from \( G/S \) to \( \mathbb{R} \), and thus studying \( R_f(G, S) \) is the same as studying \( R_f(G/S, 0) \). However, we avoid this viewpoint in this paper.

### 1.4 Extreme functions and their classification

In polyhedral combinatorics, one is interested in classifying the facet-defining inequalities of a polytope, which are the strongest inequalities and provide a finite minimal description. In the infinite group problem, the analogous notion is that of an \textit{extreme function}.

A valid function \( \pi \) is \textit{extreme} for \( R_f(G, S) \) if it cannot be written as a convex combination of two other valid functions for \( R_f(G, S) \), i.e., \( \pi = \frac{1}{2}(\pi_1 + \pi_2) \) implies \( \pi = \pi_1 = \pi_2 \). Extreme functions are minimal.

Various sufficient conditions for extremality have been proved in the previous literature [7,9,11–13,19,24,26]. In part I [5] of the present series of papers, the authors initiated the study of perturbation functions that are equivariant with respect to certain finitely generated reflection groups. This addressed an inherent previously unknown \textit{arithmetic} (number-theoretic) aspect of the problem and allowed the authors to give an algorithm that tests extremality of piecewise linear functions with rational breakpoints and relate extremality to a finite-dimensional problem.

**Theorem 1.3** (Theorems 1.3 and 1.5 in [5]) Consider the following problem.

\[ \text{Given a minimal valid function } \pi \text{ for } R_f(\mathbb{R}, \mathbb{Z}) \text{ that is piecewise linear with a set of rational breakpoints with the least common denominator } q, \text{ decide if } \pi \text{ is extreme or not.} \]
(i) There exists an algorithm for this problem that takes a number of elementary operations over the reals that is bounded by a polynomial in \( q \).

(ii) If the function \( \pi \) is continuous, then \( \pi \) is extreme for \( R_f(\mathbb{R}, \mathbb{Z}) \) if and only if the restriction \( \pi \big|_{\frac{1}{4q}\mathbb{Z}} \) is extreme for the finite group problem \( R_f(\frac{1}{4q}\mathbb{Z}, \mathbb{Z}) \).

1.5 Contributions, techniques, and outline of this paper

In the present paper, we continue the program of [5] of algorithmically studying the extremality of piecewise linear functions. We prove several general results that hold for arbitrary dimension \( k \) and then apply them to give an algorithm that tests the extremality of a large class of functions for the case \( k = 2 \). The structure of the paper is outlined in Fig. 1.

The main technique used to show a function \( \pi \) is extreme is to assume that \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \) where \( \pi^1, \pi^2 \) are valid functions, and then show that \( \pi = \pi^1 = \pi^2 \). We will use three important properties of \( \pi^1, \pi^2 \) in our proofs, which are summarized in the following lemma. These facts for the one-dimensional case can be found, for instance, in [5], and are easily extended to the general \( k \)-dimensional case.

Lemma 1.4 Let \( \pi \) be minimal, \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \), and \( \pi^1, \pi^2 \) valid functions. Then the following hold:

(i) \( \pi^1, \pi^2 \) are minimal.
(ii) All subadditivity relations \( \pi(x + y) \leq \pi(x) + \pi(y) \) that are tight for \( \pi \) are also tight for \( \pi^1, \pi^2 \). That is, defining the additivity domain of \( \pi \) as

\[
E(\pi) := \{(x, y) \mid \Delta \pi(x, y) := \pi(x) + \pi(y) - \pi(x + y) = 0\},
\]

we have \( E(\pi) \subseteq E(\pi^1), E(\pi^2) \).

(iii) If \( \pi \) is continuous and piecewise linear, then \( \pi, \pi^1, \pi^2 \) are all Lipschitz continuous.

1.5.1 Functional equations

Utilizing the set \( E(\pi) \) is fundamental in the literature to classifying extreme functions. In particular, much of the literature relies on a bounded version of a result for the classical (additive) Cauchy functional equation

\[
\theta(u) + \theta(v) = \theta(u + v),
\]

where \( u, v \in \mathbb{R} \) (see, e.g., [1,10,21–23]). This result is known as the Interval Lemma in the integer programming community [19].

Lemma 1.5 (Interval lemma [4,19]) Let \( \theta : \mathbb{R} \rightarrow \mathbb{R} \) be a function bounded on every bounded interval. Given real numbers \( u_1 < u_2 \) and \( v_1 < v_2 \), let \( U = [u_1, u_2], V = [v_1, v_2] \), and \( U + V = [u_1 + v_1, u_2 + v_2] \). If \( \theta(u) + \theta(v) = \theta(u + v) \) for every \( (u, v) \in U \times V \), then \( \theta \) is affine with the slope \( c \in \mathbb{R} \) in each of the intervals \( U, V \), and \( U + V \).

The Interval Lemma gives a powerful dimension reduction mechanism: where it applies, the infinite-dimensional space of functions on an interval is replaced by a finite-dimensional space. If this applies to all subintervals of a piecewise linear function, testing if this function is extreme can be reduced to finite-dimensional linear algebra.

For the \( k \)-dimensional case, various authors in the integer programming community have given suitable generalizations of this lemma [7,9,11]. There is also a parallel line of work in the functional equations literature, e.g., [21,23,25]. In the present paper, we state and prove a certain version of these results which allows for additivity relations to hold on lower dimensional domains. To the best of our knowledge, this lower dimensional variant of such functional equations is new. We treat directly the so-called Pexider equation, which is a simple generalization that allows for three functions instead of one that is well-studied in the functional equations community, but not as much in the integer programming community. This generalization comes at no cost in the proofs. The utility of considering it in this generality will become apparent in a following paper [6].

While the novelty of this paper is the lower dimensional variant of the Pexider equations proved in Theorems 2.5 and 2.11, for the expository purposes of this introduction we state two consequences whose statements are cleaner. Nonetheless, these next two results are extremely useful for understanding extremality, in our opinion.

Theorem 1.6 (Higher-dimensional Interval Lemma, full-dimensional version) Let \( f, g, h : \mathbb{R}^k \rightarrow \mathbb{R} \) be bounded functions. Let \( U \) and \( V \) be convex subsets of \( \mathbb{R}^k \) such that

\[
\Delta f(x, y) := f(x) + f(y) - f(x + y) = 0,
\]

\[
\Delta g(x, y) := g(x) + g(y) - g(x + y) = 0,
\]

\[
\Delta h(x, y) := h(x) + h(y) - h(x + y) = 0.
\]
f(u) + g(v) = h(u + v) for all (u, v) ∈ U × V. Assume that aff(U) = aff(V) = R^k. Then there exists a vector c ∈ R^k such that f, g and h are affine over U, V and W = U + V, respectively, with the same gradient c.

The key generalization is to consider an additivity domain specified by a general convex set F ⊆ R^k × R^k instead the more restrictive setting of F = U × V.

Define the projections p_1, p_2, p_3: R^k × R^k → R^k as

\[ p_1(x, y) = x, \quad p_2(x, y) = y, \quad p_3(x, y) = x + y. \]  

Theorem 1.7 (Convex additivity domain lemma, full-dimensional version) Let f, g, h: R^k → R be bounded functions. Let F ⊆ R^k × R^k be a full-dimensional convex set such that f(u) + g(v) = h(u + v) for all (u, v) ∈ F. Then there exists a vector c ∈ R^k such that f, g and h are affine over int(p_1(F)), int(p_2(F)) and int(p_3(F)), respectively.

While Theorems 1.6 and 1.7 are simple corollaries of our Theorems 2.5 and 2.11, we mention here that they also follow immediately from the main result of [25] (see Theorem 2.1 for a statement of the result from [25]). It is notable that we can only deduce affine linear properties over the interiors of the projections. This is best possible, as we illustrate by examples (Remarks 2.12 and 2.13).

1.5.2 Piecewise linear functions and the discrete geometry of their additivity domains

Piecewise linear functions form an important class of minimal valid functions. In fact, all classes of extreme functions described in the literature are piecewise linear, with the exception of a family of measurable functions constructed in [4].

In the one-dimensional case (k = 1), a continuous piecewise linear function \( \pi \) periodic modulo \( \mathbb{Z} \) is given by a list of breakpoints in [0, 1] and affine functions on the subintervals delimited by these breakpoints. If the value of \( \pi \) is known on the breakpoints, then \( \pi \) is already uniquely defined everywhere by linear interpolation.
In the higher-dimensional case \((k > 1)\), it is not enough to give a list of breakpoints; rather, one needs a triangulation. As our prime example for \(k = 2\), consider the function shown in Fig. 2. Its pieces are defined on the lower and upper triangles

\[
\begin{align*}
\theta_0 &= \frac{1}{q} \text{conv} \left( \left\{ \left( \begin{array}{c} 0 \\ 0 \end{array} \right), \left( \begin{array}{c} 0 \\ 1 \end{array} \right) \right\} \right) \quad \text{and} \quad \theta_1 &= \frac{1}{q} \text{conv} \left( \left\{ \left( \begin{array}{c} 1 \\ 0 \end{array} \right), \left( \begin{array}{c} 0 \\ 1 \end{array} \right), \left( \begin{array}{c} 1 \\ 1 \end{array} \right) \right\} \right)
\end{align*}
\]

(with \(q = 5\)) and their translates by elements of the lattice \(\frac{1}{q}\mathbb{Z}^2\). Together these triangles form a well-known\(^1\) triangulation of the space \(\mathbb{R}^2\), which is, of course, periodic modulo \(\mathbb{Z}^2\). It has convenient geometric and arithmetic properties and will play an important role in the present paper; we denote it by \(\mathcal{P}_q\).

In general we describe piecewise linear functions \(\pi : \mathbb{R}^k \to \mathbb{R}\) by specifying a polyhedral complex \(\mathcal{P}\) (a collection of polyhedra, meeting face-to-face; see Sect. 3) that covers all of \(\mathbb{R}^k\) and affine functions on the cells of this complex. The use of polyhedral complexes generalizes that of triangulations.

1.5.3 Combinatorial representation of additivity domain through \(\mathcal{P}\)

Our second main contribution in the present paper is a detailed study of the discrete geometry of the additivity domain \(E(\pi)\), as defined in (2), of a function \(\pi\) that is continuous piecewise linear on a polyhedral complex \(\mathcal{P}\). This is missing from the previous literature on \(R_f(\mathbb{R}^k, \mathbb{Z}^k)\) for \(k \geq 2\) and extends the discussion in the one-dimensional case in [5]. In Sect. 3.2, we show that the subadditivity slack function \(\Delta \pi\) (as defined in (2)) is continuous piecewise linear over a polyhedral complex in \(\mathbb{R}^k \times \mathbb{R}^k\) that we call \(\Delta \mathcal{P}\). Therefore, \(E(\pi)\) is composed of faces of \(\Delta \mathcal{P}\) on which the piecewise linear function \(\Delta \pi\) is constantly zero, which can be determined completely by the values of \(\Delta \pi\) at the vertices of \(\Delta \mathcal{P}\). It follows that the vertices of \(\Delta \mathcal{P}\) hold information for necessary and sufficient conditions for minimality, as shown in Theorem 3.10. The faces of \(\Delta \mathcal{P}\) that are contained in \(E(\pi)\) are referred to as \(\text{additive faces}\) and are partially ordered by set inclusion. The inclusion-maximal faces are called the \(\text{maximal additive faces}\). In Sect. 3.4, we show that these maximal additive faces provide a combinatorial description of \(E(\pi)\) as the union of certain polytopes (Lemma 3.12). This proves to be a crucial ingredient to show that a piecewise linear function is not extreme.

Further, minimal functions can be classified according to the types of maximal additive faces \(F \in \Delta \mathcal{P}\) that appear. The \(\text{generic case}\) is that in which all maximal additive faces, with the possible exception of those corresponding to the symmetry condition, are full-dimensional in \(\mathbb{R}^k \times \mathbb{R}^k\). In this case, the Interval Lemma (for \(k = 1\)) or the full-dimensional version of the Higher-dimensional Interval Lemma (for \(k \geq 2\)) are sufficient for proving extremality. All sufficient conditions for extremality studied in the previous literature fall into this class. \(\text{Degenerate cases}\), in which some maximal additive faces are lower-dimensional, require more machinery.

In [5], the authors examine functions for \(k = 1\) with rational breakpoints. They interpret lower-dimensional maximal additive faces as translation and reflection operations on the real line. Using the structure of these operations, a special class of “perturbation” functions is introduced in [5], which are used as certificates for the non-extremality

---

\(^1\) For example, in the context of homotopy methods [15], this triangulation is known as the K1 triangulation.
of a given minimal function. Understanding the nature of these lower-dimensional maximal additive faces and their interaction with these perturbation functions was the key to breaking beyond the existing arguments from the literature which dealt with only full-dimensional maximal additive faces for the $k = 1$ case.

For higher dimensions, degenerations of various types are possible and define a hierarchy of functions. Just like the situation in the $k = 1$ case suggests, as one climbs up in this hierarchy, the extremality proofs become more and more complex. In this paper, we initiate this higher-dimensional theory by studying the $k = 2$ case, for piecewise linear functions over a special triangulation of $\mathbb{R}^2$ and a particular type of degeneration only.

1.5.4 Characterization of extreme piecewise linear functions on a standard triangulation of the plane

In the present paper, we restrict ourselves to functions on the triangulation $\mathcal{P}_q$ that have a particular type of degeneration of the maximal additive faces only. These functions are called *diagonally constrained* functions; the definition appears in Sect. 4. (The example function shown in Fig. 2 is a diagonally constrained function.)

In the following two theorems, we require that $f \in \text{vert}(\mathcal{P}_q)$. This turns out to be a natural assumption because for minimal functions that cannot be viewed as a lower-dimensional function, we must always have $f \in \text{vert}(\mathcal{P})$, Theorem B.11. Such functions are called *genuinely $k$-dimensional* and were studied in [7,9]. We detail properties of these functions in “Appendix 2”. In particular, we show that the study of continuous piecewise linear extreme functions can, under some mild assumptions, be reduced to the study of genuinely $k$-dimensional functions that are continuous and piecewise linear.

**Theorem 1.8** Consider the following problem.

*Given a minimal valid function $\pi$ for $R_f(\mathbb{R}^2, \mathbb{Z}^2)$ that is piecewise linear continuous on $\mathcal{P}_q$ and diagonally constrained with $f \in \text{vert}(\mathcal{P}_q)$, decide if $\pi$ is extreme.*

There exists an algorithm for this problem that takes a number of elementary operations over the reals that is bounded by a polynomial in $q$.

As a direct corollary of the proof of Theorem 1.8, we obtain the following result relating the finite and infinite group problems.

**Theorem 1.9** Let $\pi$ be a minimal continuous piecewise linear function over $\mathcal{P}_q$ that is diagonally constrained and $f \in \text{vert}(\mathcal{P}_q)$. Fix $m \in \mathbb{Z}_{\geq 3}$. Then $\pi$ is extreme for $R_f(\mathbb{R}^2, \mathbb{Z}^2)$ if and only if the restriction $\pi\big|_{\frac{1}{mq}\mathbb{Z}^2}$ is extreme for $R_f\left(\frac{1}{mq}\mathbb{Z}^2, \mathbb{Z}^2\right)$.

The two main developments for the proof of Theorems 1.8 and 1.9 are an understanding of how additivities combine to imply piecewise linear conditions, such as Theorem 1.7, and how perturbation functions can imply a function is not extreme. Specific perturbation functions are described in Sect. 5.2. In “Appendix 1”, we give a more abstract discussion of how perturbation functions can be understood through reflection groups. The proof of Theorems 1.8 and 1.9 is completed in Sect. 5.5.
2 Regular solutions to Cauchy’s functional equation on restricted domains of $\mathbb{R}^k$

2.1 Cauchy’s and Pexider’s functional equations

As mentioned in the introduction, the standard technique for showing extremality of a minimal valid function $\pi : \mathbb{R}^k \to \mathbb{R}$ is as follows. Suppose that $\pi = \frac{1}{2}(\pi^1 + \pi^2)$, where $\pi^1, \pi^2$ are other (minimal) valid functions. One then studies the additivity domain $E(\pi)$. By Lemma 1.4, $E(\pi) \subseteq E(\pi^1), E(\pi^2)$. One then considers $\pi, \pi^1, \pi^2$ as solutions to the functional equation

$$\theta(u) + \theta(v) = \theta(u + v), \quad (u, v) \in F,$$

where $F = E(\pi)$.

This equation is known as the (additive) Cauchy functional equation. Classically (see, e.g., [10, 23]), it is studied for functions $\theta : \mathbb{R}^k \to \mathbb{R}$, when the additivity domain $F$ is the entire space $\mathbb{R}^k \times \mathbb{R}^k$. The solutions to (5) with $F = \mathbb{R}^k \times \mathbb{R}^k$ are referred to as additive functions. The obvious solutions to (5), namely the (homogeneous) linear functions $\theta(x) = c \cdot x$, are referred to as the regular solutions. In addition, there exist certain pathological solutions, which are highly discontinuous. In order to rule out these solutions, one imposes a regularity hypothesis. Various such regularity hypotheses have been proposed in the literature. For example, it is sufficient to assume that the function $\theta$ is bounded on bounded intervals, or continuous at a point, or bounded below on a finite interval, or locally Lebesgue integrable; see [21, Theorem 1.2] for a list of many more equivalent conditions. Under each of these conditions, one deduces that the additive function $\theta : \mathbb{R}^k \to \mathbb{R}$ is continuous and hence a (homogeneous) linear function [21, Theorems 1.1 and 1.2].

A natural and commonly studied generalization of the Cauchy functional equation is the Pexider equation

$$f(u) + g(v) = h(u + v), \quad (u, v) \in F,$$

where $f, g, h : \mathbb{R}^k \to \mathbb{R}$. When $F = \mathbb{R}^k \times \mathbb{R}^k$, it is easily shown that the solutions to the Pexider equation are $f(x) = \theta(x) + \alpha, g(y) = \theta(y) + \beta, h(z) = \theta(z) + \alpha + \beta$ for some additive function $\theta$ satisfying (5) [21]. Hence, this equation on the entire domain reduces to studying the Cauchy functional equation. Combining this with a regularity condition, we find that the regular solutions are affine functions; so we lose homogeneity of the solutions.

2.2 Restricted additivity domains

The additivity domain $E(\pi)$ of a subadditive function $\pi : \mathbb{R}^k \to \mathbb{R}$ can be a complicated set. It is convenient to break it into convex sets $F$, which we then study independently.
When \( F \subseteq \mathbb{R}^k \times \mathbb{R}^k \), Eqs. (5) and (6) are referred to as conditional Cauchy and Pexider equations or as Cauchy and Pexider equations on restricted domains \([14,22]\). It is clear that the Pexider equation imposes no conditions on the function values of \( f, g, \) and \( h \) outside of the projections \( p_1(F), p_2(F), \) and \( p_3(F) \), respectively, where the projections are as defined in (4). Baker and Radó \([25]\) show that when the Pexider equation is satisfied on a restricted open path-connected domain, then the solutions on each of the projections are constant shifts of the same additive function \( \theta: \mathbb{R}^k \rightarrow \mathbb{R} \). We provide a slightly modified version of \([25, \text{Corollary} 1]\) that removes one assumption.

**Theorem 2.1** (\([25]\)) Let \( F \subseteq \mathbb{R}^k \times \mathbb{R}^k \) non-empty, path-connected, and open. Let \( f, g, h: \mathbb{R}^k \rightarrow \mathbb{R} \) such that (6) holds for all \( (x, y) \in F \). Then there exist an additive function \( \theta: \mathbb{R}^k \rightarrow \mathbb{R} \) and constants \( \alpha, \beta \in \mathbb{R} \) such that \( f(x) = \theta(x) + \alpha, g(y) = \theta(y) + \beta, \) and \( h(z) = \theta(z) + \alpha + \beta \) for all \( x \in p_1(F), y \in p_2(F), \) and \( z \in p_3(F) \).

Furthermore, let \( D \subseteq \mathbb{R}^k \times \mathbb{R}^k \) such that \( F \subseteq D \subseteq \text{cl} F \), where \( \text{cl} F \) denotes the closure of \( F \). Suppose that \( D \) satisfies the following: for every \( x \in p_1(D) \) there exist \( y \in p_2(D), z \in p_3(D) \) such that \( x + y = z \) and for every \( y \in p_2(D) \) there exist \( x \in p_1(D), z \in p_3(D) \) such that \( x + y = z \). Then \( f(x) = \theta(x) + \alpha, g(y) = \theta(y) + \beta, \) and \( h(z) = \theta(z) + \alpha + \beta \) for all \( x \in p_1(D), y \in p_2(D), \) and \( z \in p_3(D) \).

**Proof** By \([25, \text{Theorem} 1]\), there exist an additive function \( \theta: \mathbb{R}^k \rightarrow \mathbb{R} \) and constants \( \alpha, \beta \in \mathbb{R} \) such that \( f(x) = \theta(x) + \alpha, g(y) = \theta(y) + \beta, \) and \( h(z) = \theta(z) + \alpha + \beta \) for all \( x \in p_1(F), y \in p_2(F), \) and \( z \in p_3(F) \). Let \( x \in p_1(D), y \in p_2(F), z \in p_3(F) \) such that \( x + y = z \). Then \( f(x) = h(z) - g(y) = \theta(z) - \theta(y) + \alpha = \theta(x) + \alpha \). Similarly, for any \( y \in p_2(D), g(y) = \theta(y) + \beta \). Finally, for any \( z \in p_3(D), \) there exists a preimage \((x, y) \in D\) such that \( z = x + y \). Then \( h(z) = f(x) + g(y) = \theta(x) + \theta(y) + \alpha + \beta = \theta(z) + \alpha + \beta \). \(\square\)

Hence, combined with a regularity condition, affine properties of the functions on the projections can be deduced.

### 2.3 Interval lemma in \( \mathbb{R}^4 \)

The so-called Interval Lemma was introduced by Gomory and Johnson to the integer programming community in \([19]\).\(^2\) It concerns the Cauchy functional equation (5) on a restricted additivity domain \( F \) that is a rectangle \( F = U \times V \), where \( U \) and \( V \) are bounded intervals. Then \( p_1(F) = U, p_2(F) = V, \) and \( p_3(F) = U + V, \) a Minkowski sum. We present it here as a corollary of Theorem 2.1, together with regularity conditions.

The following lemma is stated with the regularity assumption that \( f, g, h \) are bounded functions; but this assumption can be replaced by any of the other regularity assumptions discussed above.

\(^2\) Similar results were known independently in the functional equations community. For instance, \([1]\) states the result for \( U = V \).
Lemma 2.2 (Interval lemma) Given real numbers \( u_1 < u_2 \) and \( v_1 < v_2 \), let \( U = [u_1, u_2] \), \( V = [v_1, v_2] \), and \( U + V = [u_1 + v_1, u_2 + v_2] \). Let \( f : U \rightarrow \mathbb{R} \), \( g : V \rightarrow \mathbb{R} \), \( h : U + V \rightarrow \mathbb{R} \) be bounded functions. If \( f(u) + g(v) = h(u + v) \) for every \((u, v) \in U \times V\), then there exists \( c \in \mathbb{R} \) such that \( f(u) = f(u_1) + c(u - u_1) \) for every \( u \in U \), \( g(v) = g(v_1) + c(v - v_1) \) for every \( v \in V \), \( h(w) = h(u_1 + v_1) + c(w - u_1 - v_1) \) for every \( w \in U + V \). In other words, \( f \), \( g \) and \( h \) are affine with slope \( c \) over \( U \), \( V \), and \( U + V \) respectively.

**Proof** Consider the rectangle \( D = U \times V \subseteq \mathbb{R}^2 \) and let \( F = \text{int}(D) \). Since \( U \) and \( V \) are proper intervals, for every \( x \in U \), there exists a \( y \in \text{int}(V) \) such that \( x + y \in \text{int}(U + V) = p_2(F) \). Similarly, for every \( y \in V \), there exists a \( x \in \text{int}(U) \) such that \( x + y \in \text{int}(U + V) = p_2(F) \). Therefore, by Theorem 2.1, there exists an additive function \( \theta : \mathbb{R} \rightarrow \mathbb{R} \) and constants \( \alpha, \beta \in \mathbb{R} \) such that \( f(x) = \theta(x) + \alpha \), \( g(y) = \theta(y) + \beta \), \( h(z) = \theta(z) + \alpha + \beta \) for all \( x \in U \), \( y \in V \), \( z \in p_2(D) = U + V \).

Since \( f \) is bounded on \( U \), \( \theta \) is bounded on \( U \). Therefore, by [21, Theorems 1.1 and 1.2], \( \theta(x) = cx \) for some \( c \in \mathbb{R} \). This completes the proof. \( \square \)

2.4 Higher-dimensional Interval Lemma

The generalization of the Interval Lemma for hypercubes \( U = V = [a, b]^k \) was stated in [1]. The only known generalizations of Lemma 2.2 in the integer programming community literature appear in [9,11] for the case of \( k = 2 \) and in [7] for general \( k \). The results in [7,9] are special cases of our Theorem 2.5 that require one of the sets to intersect the origin. The result in [11] applies in \( k = 2 \) and allows for so-called star-shaped sets that also contain the origin; a similar proof to our generalization also yields a result on star-shaped sets, but we avoid this direction because we do not need this type of result.

In fact, the proof of Lemma 2.2 easily generalizes to the \( k \)-dimensional setting to prove Theorem 1.6. This is because the result of Baker and Radó (Theorem 2.1) also applies in the \( k \)-dimensional setting. Then the problem reduces to \( k \) separate one-dimensional problems since any additive function \( \theta : \mathbb{R}^k \rightarrow \mathbb{R} \) can be decomposed into \( k \) univariate additive functions [21, Theorem 1.24]. This is under the assumption that the domains of \( U \), \( V \) of \( f \), \( g \) are full-dimensional and the additivity domain is the full Cartesian product \( U \times V \).

We prove the result in a more general setting, in which the additivity domain is \( U \times V \) for convex sets \( U \subseteq \mathbb{R}^k \) and \( V \subseteq \mathbb{R}^k \), which are not necessarily of the same dimension. In this general setting we cannot expect to deduce that the solutions are affine over \( U \), \( V \), and \( U + V \). In particular, these results will differ from most literature since the domain of additivity is not full-dimensional.

**Remark 2.3** Indeed, if \( U + V \) is a direct sum, i.e., for every \( w \in U + V \) there is a unique pair \( u \in U \), \( v \in V \) with \( w = u + v \), then \( f(u) + g(v) = h(u + v) \) merely expresses a form of separability of \( h \) with respect to certain subspaces, and \( f \) and \( g \) can be arbitrary functions; see Fig. 3c.
Definition 2.4 Let \( U \subseteq \mathbb{R}^k \). Given a linear subspace \( L \subseteq \mathbb{R}^k \), we say \( \pi : U \rightarrow \mathbb{R} \) is affine with respect to \( L \) over \( U \) if there exists \( c \in \mathbb{R}^k \) such that \( \pi(u^2) - \pi(u^1) = c \cdot (u^2 - u^1) \) for any \( u^1, u^2 \in U \) such that \( u^2 - u^1 \in L \).

Theorem 2.5 (Higher-dimensional Interval Lemma) Let \( f, g, h : \mathbb{R}^k \rightarrow \mathbb{R} \) be bounded functions. Let \( U \) and \( V \) be convex subsets of \( \mathbb{R}^k \) such that \( f(u) + g(v) = h(u + v) \) for all \( (u, v) \in F = U \times V \). Let \( L \) be a linear subspace of \( \mathbb{R}^k \) such that \( (L + U) \times (L + V) = (L \times L) + F \subseteq \text{aff}(F) = \text{aff}(U) \times \text{aff}(V) \). Then there exists a vector \( c \in \mathbb{R}^k \) such that \( f, g \) and \( h \) are affine with respect to \( L \) over \( p_1(F) = U \), \( p_2(F) = V \) and \( p_3(F) = U + V \) respectively, with gradient \( c \).

For the proof, we will only use the machinery of Lemma 2.2. We note that certain elements of the proof could also be done using Theorem 2.1, but there does not seem to be a direct implication.

We will need the following notation and basic result. For any element \( x \in \mathbb{R}^k \), \( k \geq 1 \), \( |x|_{\infty} \) will denote the standard \( \ell^\infty \) norm. We use \( B^\infty(u, r) \) to denote the open \( \ell^\infty \) ball around \( u \in \mathbb{R}^k \) with radius \( r \in \mathbb{R}_+ \), i.e., \( B^\infty(u, r) = \{ x \in \mathbb{R}^k \mid |x - u|_{\infty} < r \} \).

Lemma 2.6 Let \( U \subseteq \mathbb{R}^k \) be a convex set and let \( L \) be a linear space such that \( L + U \subseteq \text{aff}(U) \). Then, for any \( u \in \text{rel int}(U) \), there exists \( r > 0 \) such that \( B^\infty(u, r) \cap (u + L) \subseteq U \).

Proof It suffices to show that for any \( p \in L \) there exists \( \epsilon > 0 \) such that \( u + \epsilon p \in U \). One then can use a basis of \( L \) to find the desired \( r > 0 \).

Since \( L + U \subseteq \text{aff}(U) \), \( L \) is a subspace of \( \text{aff}(U) - u \). Thus, \( p \in \text{aff}(U) - u \) and therefore, \( u + p \in \text{aff}(U) \). Since \( U \) is convex and \( u \in \text{rel int}(U) \), there exists \( \epsilon > 0 \) such that \( u + \epsilon p \in U \). \( \Box \)

Proof of Theorem 2.5 If \( m := \dim(L) = 0 \), there is nothing to prove. So we assume \( m \geq 1 \) and let \( p^1, \ldots, p^m \) be a basis for \( L \) (we obviously have \( m \leq k \)). Since \( U \) is convex and \( L + U \subseteq \text{aff}(U) \), by Lemma 2.6 for any vector \( u^0 \in \text{rel int}(U) \), there exist real numbers \( u^i_1 < 0 < u^i_2 \) such that the set \( U_0 := \{ u^0 + \sum_{i=1}^m \lambda_i p^i \mid u^i_1 \leq \lambda_i \leq u^i_2, \forall i = 1, \ldots, m \} \subseteq U \). Similarly, for any vector \( v^0 \in \text{rel int}(V) \), there exist real numbers \( v^i_1 < 0 < v^i_2 \) such that the set \( V_0 := \{ v^0 + \sum_{i=1}^m \mu_i p^i \mid v^i_1 \leq \mu_i \leq v^i_2, \forall i = 1, \ldots, m \} \subseteq V \).
Fix some \( u^0 \in \text{rel int}(U) \), \( v^0 \in \text{rel int}(V) \) and \( i \in \{1, \ldots, m\} \). Let \( u^i_1 \leq \tilde{\lambda}_j \leq u^i_2 \) and \( v^i_1 \leq \tilde{\mu}_j \leq v^i_2 \), for \( j \neq i \), be real numbers. We consider the two line segments

\[
\left\{ u^0 + \sum_{j \neq i}^m \tilde{\lambda}_j p^j + \lambda_i p^i \mid u^i_1 \leq \lambda_i \leq u^i_2 \right\} \subseteq U_0,
\]

\[
\left\{ v^0 + \sum_{j \neq i}^m \tilde{\mu}_j p^j + \mu_i p^i \mid v^i_1 \leq \mu_i \leq v^i_2 \right\} \subseteq V_0.
\]

Let \( f^i : [u^i_1, u^i_2] \rightarrow \mathbb{R} \) be defined by \( f^i(\lambda) = f(u^0 + \sum_{j \neq i}^m \tilde{\lambda}_j p^j + \lambda p^i) \), \( g^i : [v^i_1, v^i_2] \rightarrow \mathbb{R} \) be defined by \( g^i(\lambda) = g(v^0 + \sum_{j \neq i}^m \tilde{\mu}_j p^j + \lambda p^i) \) and \( h^i : [u^i_1 + v^i_1, u^i_2 + v^i_2] \rightarrow \mathbb{R} \) be defined by \( h^i(\lambda) = h(u^0 + v^0 + \sum_{j \neq i}^m (\tilde{\lambda}_j + \tilde{\mu}_j) p^j + \lambda p^i) \).

Applying Lemma 2.2, there exists a constant \( \hat{c}_i \in \mathbb{R} \) such that

\[
f^i(u^0 + \sum_{j \neq i}^m \tilde{\lambda}_j p^j + \lambda p^i) = f(u^0 + \sum_{j \neq i}^m \tilde{\lambda}_j p^j) + \hat{c}_i \cdot \lambda \quad \text{for all } \lambda \in [u^i_1, u^i_2],
\]

\[
g^i(v^0 + \sum_{j \neq i}^m \tilde{\mu}_j p^j + \lambda p^i) = g(v^0 + \sum_{j \neq i}^m \tilde{\mu}_j p^j) + \hat{c}_i \cdot \lambda \quad \text{for all } \lambda \in [v^i_1, v^i_2].
\]

Notice that this argument could be made with any other values of \( \tilde{\lambda}_j, j \neq i \) while using the same \( \tilde{\mu}_j, j \neq i \). Thus, \( \hat{c}_i \) is independent of the values of \( \tilde{\lambda}_j, j \neq i \). Thus, we have \( m \) real numbers \( \hat{c}_i, i = 1, \ldots, m \), that only depend on \( f, g, h, L \) and the two points \( u^0 \in \text{rel int}(U) \) and \( v^0 \in \text{rel int}(V) \), and (7) holds for any values of \( u^i_1 \leq \tilde{\lambda}_j \leq u^i_2, j \neq i \).

We choose \( c \in \mathbb{R}^k \) satisfying \( c \cdot p^i = \hat{c}_i \) for all \( i = 1, \ldots, m \) (this can be done since \( p^1, \ldots, p^m \) are linearly independent). Now for any \( p \in L \) such that \( u^0 + p \in U_0 \), we can represent \( p = \sum_{i=1}^m \lambda_i p^i \) for some \( u^i_1 \leq \lambda_i \leq u^i_2, i = 1, \ldots, m \). Thus, \( f(u^0 + p) = f(u^0 + \sum_{i=1}^m \lambda_i p^i) \).

Now using (7) with \( i = m \) we have

\[
f\left( u^0 + \sum_{i=1}^m \lambda_i p^i \right) = f\left( u^0 + \sum_{i=1}^{m-1} \lambda_i p^i + \lambda_m p^m \right)
\]

\[
= f\left( u^0 + \sum_{i=1}^{m-1} \lambda_i p^i \right) + \hat{c}_m \cdot \lambda_m,
\]

which follows because the \( \hat{c}_i \)'s do not depend on the particular values \( \lambda_i, i \neq m \). By applying this argument iteratively, we find that

\[\text{ Springer}\]
Thus, \( f(u^0 + p) = f(u^0) + c \cdot p \) for all \( p \) such that \( u^0 + p \in U_0 \), i.e., \( f \) is affine with respect to \( L \) over \( U_0 \) with gradient \( c \). This argument can also be used to show that \( g \) is affine with respect to \( L \) over \( V_0 \) with the same gradient \( c \) (the relations in (7) will now be used on \( g \), keeping \( \lambda, j \neq i \) fixed and allowing \( \mu, j \neq i \) to vary).

Finally, we do one more step to show that \( f \) is affine with respect to \( L \) over all of \( U \) with gradient \( c \). Let \( u^1, u^2 \in U \) such that \( u^2 - u^1 = p' \in L \). Let \( v^0_1 < v^0_2 \in \mathbb{R} \), \( i = 1, \ldots, m \) be such that \( \{v^0 + \lambda p' \mid v^0 \leq \lambda \leq v^0_{i+1}\} \subseteq V_0 \).

Let \( f^0 : [0, 1] \to \mathbb{R} \) be defined by \( f^0(\lambda) = f(u^1 + \lambda p') \), \( g^0 : [v^0_1, v^0_2] \to \mathbb{R} \) be defined by \( g^0(\lambda) = g(v^0 + \lambda p') \) and \( h^0 : [0 + v^0_1, 1 + v^0_2] \to \mathbb{R} \) be defined by \( h^0(\lambda) = h(u^1 + v^0 + \lambda p') \). Applying Lemma 2.2 to \( f^0, g^0 \) and \( h^0 \), there exists a constant \( \tilde{c}_0 \in \mathbb{R} \) such that

\[
\begin{align*}
  f(u^1 + \lambda p') &= f(u^1) + \tilde{c}_0 \cdot \lambda & \text{for all } \lambda \in [0, 1], \quad (8a) \\
g(v^0 + \lambda p') &= g(v^0) + \tilde{c}_0 \cdot \lambda & \text{for all } \lambda \in [v^0_1, v^0_2]. \quad (8b)
\end{align*}
\]

Since \( g \) is affine over \( V_0 \) with gradient \( c \), \( g(v^0 + \lambda p') = g(v^0) + \lambda (c \cdot p') \) for all \( \lambda \in [v^0_1, v^0_2] \). Thus, \( \tilde{c}_0 = c \cdot p' \). Using (8a), we get \( f(u^1 + p') = f(u^1) + \tilde{c}_0 = f(u^1) + c \cdot p' \). Therefore, \( f(u^2) - f(u^1) = c \cdot p' \) as required. The same argument applies for proving \( g \) is affine with respect to \( L \) over \( V \) with gradient \( c \). Finally, since \( h(x + y) = f(x) + g(y) \) for all \( x \in U, y \in V \), it follows that \( h \) is affine with respect to \( L \) over \( U + V \) with gradient \( c \).

\[\square\]

### 2.5 Pexider functional equation on convex additivity domains in \( \mathbb{R}^k \)

We now prove a technical lemma which can be used to transfer affine properties using small “patches” within a larger domain. This will allow us to connect local applications of the Higher-dimensional Interval Lemma (Theorem 2.5) within convex sets. This lemma’s arguments have been explicitly and implicitly used in the integer programming literature \([5,7,9,11,13,17–19,24]\), as well as the functional equations literature \([21,25]\).

**Lemma 2.7** (Patching lemma) Let \( U \subseteq \mathbb{R}^k \) be a convex subset. Let \( \pi : U \to \mathbb{R} \) be any function. Suppose \( r : U \to \mathbb{R} \) is a function such that for every \( u \in U \),
(i) \( r(u) > 0 \), and
(ii) \( \pi \) is affine on \( B^\infty(u, r(u)) \cap U \).

Then \( \pi \) is affine on all of \( U \).

**Proof** If \( U \) is empty there is nothing to show. Fix any \( u^0 \in U \). Since \( \pi \) is affine on \( B^\infty(u^0, r(u^0)) \cap U \), there exists \( c \in \mathbb{R}^k \) such that \( \pi(u) - \pi(u^0) = c \cdot (u - u^0) \) for every \( u \in B^\infty(u^0, r(u^0)) \cap U \). We claim that \( \pi(u) - \pi(u^0) = c \cdot (u - u^0) \) for every \( u \in U \). This will establish the lemma. Indeed, consider \( u^1, u^2 \in U \). \( \pi(u^2) - \pi(u^1) = (\pi(u^2) - \pi(u^0)) + (\pi(u^0) - \pi(u^1)) = c \cdot (u^2 - u^0) - c \cdot (u^1 - u^0) = c \cdot (u^2 - u^1) \).

Consider any arbitrary \( u \in U \) and the line segment \([u, u^0] \subseteq U \). For every \( x \in [u, u^0] \), consider \( B^\infty(x, r(x)) \). Since \( r(x) > 0 \) for all \( x \in U \), \( \bigcup_{x \in [u, u^0]} B^\infty(x, r(x)) \) is an open cover of \([u, u^0]\). Thus, there exists a finite subcover from this open cover. In particular, there exist points \( x^0, x^1, \ldots, x^n \in [u, u^0] \) such that the following hold:

(i) \( u^0 \in B^\infty(x^0, r(x^0)) \cap U \),
(ii) \( u \in B^\infty(x^n, r(x^n)) \cap U \), and
(iii) \( (B^\infty(x^{i-1}, r(x^{i-1})) \cap U) \cap (B^\infty(x^i, r(x^i)) \cap U) \neq \emptyset \) for every \( i = 1, \ldots, n \).

First, because of (i) and the facts that \( \pi \) is affine on \( B^\infty(x^0, r(x^0)) \cap U \) and \( \pi \) is affine on \( B^\infty(u^0, r(u^0)) \cap U \) with gradient \( c \), we conclude that \( \pi \) is affine with gradient \( c \) on \( B^\infty(x^0, r(x^0)) \cap U \). From (iii), we know that \( (B^\infty(x^{i-1}, r(x^{i-1})) \cap U) \cap (B^\infty(x^i, r(x^i)) \cap U) \neq \emptyset \). Since \( \pi \) is affine on \( B^\infty(x^0, r(x^0)) \cap U \) with gradient \( c \) and \( \pi \) is affine over \( B^\infty(x^1, r(x^1)) \cap U \), we conclude \( \pi \) is affine over \( B^\infty(x^1, r(x^1)) \cap U \) with gradient \( c \). Applying this argument repeatedly, we have that \( \pi \) is affine on each \( B^\infty(x^i, r(x^i)) \cap U \) with the same gradient \( c \). Choose \( y^i, i = 1, \ldots, n \) as points in \( (B^\infty(x^{i-1}, r(x^{i-1})) \cap U) \cap (B^\infty(x^i, r(x^i)) \cap U) \). Therefore, since \( y^{i+1}, y^i \in B^\infty(x^i, r(x^i)) \cap U \) for every \( i = 1, \ldots, n - 1 \), we have

\[
\pi(y^{i+1}) - \pi(y^i) = c \cdot (y^{i+1} - y^i).
\]

Also, from (i) and (ii), we have

\[
\pi(y^1) - \pi(u^0) = c \cdot (y^1 - u^0), \quad \pi(u) - \pi(y^n) = c \cdot (u - y^n).
\]

Adding these equalities, together, we obtain \( \pi(u) - \pi(u^0) = c \cdot (u - u^0) \). \( \square \)

The Higher-dimensional Interval Lemma will be used to deduce affine properties from more complicated convex sets. Since we do not always have additivity on all of \( U \times V \), we prove affine properties on smaller cross products and then patch them together.

We will need the following basic lemma from convex analysis.

**Lemma 2.8** (Theorem 6.6 in [27]) Let \( C \) be a convex set in \( \mathbb{R}^n \) and let \( A \) be a linear transformation from \( \mathbb{R}^n \) to \( \mathbb{R}^m \). Then

\[
A \text{ rel int}(C) = \text{ rel int}(AC).
\]
Lemma 2.9 (Relative interior lemma) Let \( F \subseteq \mathbb{R}^k \times \mathbb{R}^k \) be a convex set. For any \( x \in \text{rel int}(p_1(F)) \), there exist \( y \in \text{rel int}(p_2(F)) \) such that \( (x, y) \in \text{rel int}(F) \) and \( p_3(x, y) = x + y \in \text{rel int}(p_3(F)) \). Similarly, for any \( y \in \text{rel int}(p_2(F)) \), there exist \( x \in \text{rel int}(p_1(F)) \) such that \( (x, y) \in \text{rel int}(F) \) and \( p_3(x, y) = x + y \in \text{rel int}(p_3(F)) \).

**Proof** Since \( p_i: \mathbb{R}^k \times \mathbb{R}^k \to \mathbb{R}^k \) are linear transformations for \( i = 1, 2, 3 \), by Lemma 2.8, we have \( p_i(\text{rel int}(F)) = \text{rel int}(p_i(F)) \). Therefore, \( p_i: \text{rel int}(F) \to \text{rel int}(p_i(F)) \) is a well defined surjective map.

We only prove the first claim as the second has a similar proof. Let \( x \in \text{rel int}(p_1(F)) = p_1(\text{rel int}(F)) \). Hence, there exists a point \( y \in \mathbb{R}^k \) such that \( (x, y) \in \text{rel int}(F) \). Then, for \( i = 2, 3 \), \( p_i(x, y) \in p_i(\text{rel int}(F)) = \text{rel int}(p_i(F)) \), that is, \( y \in \text{rel int}(p_2(F)) \) and \( x + y \in \text{rel int}(p_3(F)) \). \( \square \)

**Definition 2.10** For a linear space \( L \subseteq \mathbb{R}^k \) and a set \( U \subseteq \mathbb{R}^k \) such that for some \( u \in \mathbb{R}^k \) we have \( \text{aff}(U) \subseteq L + u \), we will denote by \( \text{int}_L(U) \) the interior of \( U \) in the relative topology of \( L + u \).

Note that \( \text{int}_L(U) \) is well defined because either \( \text{aff}(U) = L + u \), or \( \text{int}_L(U) = \emptyset \). We now prove our most general theorem relating to Eq. (5) on a convex domain.

**Theorem 2.11** (Convex additivity domain lemma) Let \( f, g, h: \mathbb{R}^k \to \mathbb{R} \) be bounded functions. Let \( F \subseteq \mathbb{R}^k \times \mathbb{R}^k \) be a convex set such that \( f(u) + g(v) = h(u + v) \) for all \( (u, v) \in F \). Let \( L \) be a linear subspace of \( \mathbb{R}^k \) such that \( L \times L + F \subseteq \text{aff}(F) \). Let \( (u^0, v^0) \in \text{rel int}(F) \). Then there exists a vector \( c \in \mathbb{R}^k \) such that \( f, g \) and \( h \) are affine with gradient \( c \) over \( \text{int}_L((u^0 + L) \cap p_1(F)) \), \( \text{int}_L((v^0 + L) \cap p_2(F)) \) and \( \text{int}_L((u^0 + v^0 + L) \cap p_3(F)) \), respectively.

**Proof** If \( \dim(L) = 0 \), there is nothing to prove. So we assume \( \dim(L) \geq 1 \). Let \( I = p_1(F), J = p_2(F), K = p_3(F) \).

For \( u \in \text{rel int}(I) \), define

\[
    r(u) = \sup \left\{ \frac{r}{2} \in \mathbb{R} \mid \exists v \in \mathbb{R}^k \text{ such that } B^\infty((u, v), r) \cap ((u, v) + L \times L) \subseteq F \right\}.
\]

By Lemma 2.9, for any \( u \in \text{rel int}(I) \), there exists \( v \in \text{rel int}(J) \) such that \( (u, v) \in \text{rel int}(F) \). Since \( \dim(L) \geq 1 \), Lemma 2.6 implies that \( r(u) > 0 \) for every \( u \in \text{rel int}(I) \). Let \( v \in F \) such that \( B^\infty((u, v), r(u)) \cap ((u, v) + L \times L) \subseteq F \) and let

\[
    U = p_1 \left( B^\infty((u, v), r(u)) \cap ((u, v) + L \times L) \right) = B^\infty(u, r(u)) \cap (u + L) \text{ and } V = p_2 \left( B^\infty((u, v), r(u)) \cap ((u, v) + L \times L) \right) = B^\infty(v, r(u)) \cap (v + L).
\]

Notice that

\[
    U \times V = B^\infty((u, v), r(u)) \cap ((u, v) + L \times L) \subseteq F.
\]

Hence, applying Theorem 2.5 with \( U \) and \( V \), we obtain that \( f \) is affine over \( U \). Thus, we satisfy the hypotheses of Lemma 2.7 and \( f \) is affine over \( \text{int}_L((u + L) \cap I) \) for
every \(u \in \text{rel int}(I)\). This argument can be repeated to show that \(g\) is affine over \(\text{int}_L((v + L) \cap J)\) for every \(v \in \text{rel int}(J)\).

For the pair \((u^0, v^0) \in \text{rel int}(F)\), by Lemma 2.6, there exists \(r > 0\) such that \(B^\infty((u^0, v^0), r) \cap ((u^0, v^0) + L \times L) \subseteq F\). Then for \(U_0 = B^\infty(u^0, r(u^0)) \cap (u^0 + L)\) and \(V_0 = B^\infty(v^0, r(u^0)) \cap (v^0 + L)\), we have \(U_0 \cup V_0 \subseteq F\) and Theorem 2.5 also tells us that \(f\) and \(g\) have the same gradient \(c\) in \(U_0\) and \(V_0\), respectively. Since \(f\) and \(g\) are affine in \(\text{int}_L((u^0 + L) \cap I)\) and \(\text{int}_L((v^0 + L) \cap J)\), respectively, we have that \(f\) and \(g\) are affine with the same gradient \(c\) over all \(\text{int}_L((u^0 + L) \cap I)\) and \(\text{int}_L((v^0 + L) \cap J)\), respectively. Finally, since \(f(u) + g(v) = h(u + v)\) for all \((u, v) \in F\), it follows that \(h\) is affine over \(\text{int}_L((u^0 + v^0 + L) \cap K)\). This finishes the proof. \(\square\)

**Remark 2.12** (Comparing Theorems 2.5 and 2.11) The reader might think that the Higher-dimensional Interval Lemma (Theorem 2.5) could be obtained as a corollary of Convex Additivity Domain Lemma (Theorem 2.11), by setting \(F = U \times V\). However, the Higher-dimensional Interval Lemma shows that under the appropriate additivity conditions over \(U\) and \(V\), we can obtain affine properties over all of \(U\) and \(V\) (with respect to \(L\)); whereas, the Convex Additivity Domain Lemma derives affine properties only over the interiors with respect to \(L\). This, however, cannot be avoided. In particular, there are examples satisfying the hypotheses of Convex Additivity Domain Lemma where the functions are affine over the interiors, but not on the boundaries; see [25] for such an example of a \(F \subseteq \mathbb{R} \times \mathbb{R}\) and bounded functions \(f, g, h\) that satisfy (6), but are not affine.

**Remark 2.13** (Extension not valid even with all additive relations) The example in [25] mentioned above is obtained by choosing a subset \(F \subseteq \mathbb{R} \times \mathbb{R}\) such that \(F \subseteq \{(x, y) \mid x \in p_1(F), y \in p_2(F), x + y \in p_3(F)\}\). The strict containment means that additivity does not hold for all possible pairs \((x, y) \in p_1(F) \times p_2(F)\) such that \(x + y \in p_3(F)\). We now give a similar example where the set containment is not strict, meaning that all possible additive relations from the projections are allowed. In particular, we construct an \(F \subseteq \mathbb{R}^2 \times \mathbb{R}^2\) such that \(F = \{(x, y) \mid x \in p_1(F), y \in p_2(F), x + y \in p_3(F)\}\). Let

\[
F = \text{conv}
\begin{pmatrix}
4 \\
5 \\
1
\end{pmatrix},
\begin{pmatrix}
3 \\
5 \\
2
\end{pmatrix},
\begin{pmatrix}
2 \\
4 \\
1
\end{pmatrix},
\begin{pmatrix}
1 \\
4 \\
1
\end{pmatrix},
\begin{pmatrix}
8/3 \\
35/9 \\
1
\end{pmatrix},
\begin{pmatrix}
5/2 \\
4 \\
2
\end{pmatrix},
\begin{pmatrix}
1 \\
4 \\
5
\end{pmatrix},
\begin{pmatrix}
0 \\
4 \\
5
\end{pmatrix}
\end{pmatrix}
\]

This is a full-dimensional set of \(\mathbb{R}^2 \times \mathbb{R}^2\), which has the projections

\[
U = p_1(F) = \text{conv} \begin{pmatrix}
\frac{3}{4} \\
0 \\
0
\end{pmatrix},
\]

\[
V = p_2(F) = \text{conv} \begin{pmatrix}
\frac{5}{4} \\
\frac{5}{2} \\
\frac{4}{1}
\end{pmatrix},
\]

\[
W = p_3(F) = \text{conv} \begin{pmatrix}
\frac{8}{4} \\
\frac{5}{6} \\
\frac{5}{5}
\end{pmatrix}
\]
Fig. 4 An illustration of the counterexample of Remark 2.13. The 4-dimensional simplex $F$ projects to the three closed triangles $U = p_1(F)$, $V = p_2(F)$, $W = p_3(F)$. The points $u, v, w$ are additive, i.e., $u + v = w$, but none of them is additive with any other points.

To see this, we plot the sums $U + v, V + u, w + (−U)$, $W + v, w + (−V)$, and $W + (−v)$ and show that these sets intersect $U, V, W$ only at the points $u, v, w$.

We refer to Fig. 4 for an illustration. Furthermore, it can be shown that $F = \{ (x, y) | x \in U, y \in V, x + y \in W \}$. Now define $f, g, h : \mathbb{R}^2 \to \mathbb{R}$ in the following way:

$$f(x) = \begin{cases} 1 & \text{if } x = u, \\ 0 & \text{otherwise,} \end{cases} \quad g(x) = \begin{cases} 2 & \text{if } x = v, \\ 0 & \text{otherwise,} \end{cases} \quad h(x) = \begin{cases} 3 & \text{if } x = w, \\ 0 & \text{otherwise.} \end{cases}$$

**Claim 1** $f(x) + g(y) = h(x + y)$ for all $(x, y) \in F$.

Clearly this equation holds whenever $x \neq u, y \neq v, x + y \neq w$. So suppose $x = u$. Since $(u + V) \cap W = \{w\}$ and $(W - u) \cap V = \{v\}$, the only choice for $y$ is $v$. Similarly, if we choose $y = v$, the only choice for $x$ is $u$ or if we choose $x + y = w$, the only choices for $x$ and $y$ are $u$ and $v$. We refer the reader to Fig. 4 to see these arguments illustrated. Therefore, the claim holds if and only if

$$f(x) + g(y) = h(x + y) \quad \text{for all } x \in U \setminus \{u\}, \ y \in V \setminus \{v\}, \ x + y \in W \setminus \{w\},$$

and

$$f(u) + g(v) = h(w).$$

Since all these equations hold, the claim is proved.

Observe that, since $F$ is full-dimensional, Theorem 2.11 applies with $L = \mathbb{R}^2$. We deduce affine properties over the interiors of $p_1(F) = U, p_2(F) = V$ and $p_3(F) = W$. This shows that Theorem 2.11 cannot be extended to deduce affine properties on all of $U, V, W$, unless we require further restrictions on the types of convex sets $F$ that we consider.

Of course, if we use the stronger regularity assumption that $f, g, h$ are continuous functions (rather than merely bounded functions), then the affine properties extend to the boundary as well.
Corollary 2.14 (Convex additivity domain lemma for continuous functions) Let \( f, g, h : \mathbb{R}^k \to \mathbb{R} \) be continuous functions. Let \( F \subseteq \mathbb{R}^k \times \mathbb{R}^k \) be a convex set such that \( f(u) + g(v) = h(u + v) \) for all \((u, v) \in F\). Let \( L \) be a linear subspace of \( \mathbb{R}^k \) such that \( L \times L + F \subseteq \text{aff}(F) \). Let \((u^0, v^0) \in \text{rel \, int}(F)\). Then there exists a vector \( c \in \mathbb{R}^k \) such that \( f, g \) and \( h \) are affine with gradient \( c \) over \((u^0 + L) \cap p_1(F), (v^0 + L) \cap p_2(F)\) and \((u^0 + v^0 + L) \cap p_3(F), \) respectively.

3 Discrete geometry of piecewise linear minimal valid functions and their additivity domains

3.1 Polyhedral complexes and piecewise linear functions

We introduce the notion of polyhedral complexes, which serves two purposes in our paper. First, it provides a framework to define piecewise linear functions. Second, it is a tool for studying subadditivity and additivity relations of these functions.

Definition 3.1 A polyhedral complex is a collection \( \mathcal{P} \) of polyhedra in \( \mathbb{R}^k \) such that:

(i) \( \emptyset \in \mathcal{P} \),
(ii) if \( I \in \mathcal{P} \), then all faces of the polyhedron \( I \) are in \( \mathcal{P} \),
(iii) the intersection \( I \cap J \) of two polyhedra \( I, J \in \mathcal{P} \) is a face of both \( I \) and \( J \),
(iv) \( \mathcal{P} \) is locally finite, i.e., any compact subset of \( \mathbb{R}^k \) intersects only finitely many faces in \( \mathcal{P} \).

A polyhedron \( I \) from \( \mathcal{P} \) is called a face of the complex. A polyhedral complex \( \mathcal{P} \) is called pure if all its maximal faces (with respect to set inclusion) have the same dimension. In this case, we call the maximal faces of \( \mathcal{P} \) the cells of \( \mathcal{P} \). A polyhedral complex \( \mathcal{P} \) is complete if the union of all faces of the complex is \( \mathbb{R}^k \). The reader can find examples illustrating this and the following definitions in Sect. 4.

Given a pure and complete polyhedral complex \( \mathcal{P} \), we call a function \( \pi : \mathbb{R}^k \to \mathbb{R} \) continuous piecewise linear over \( \mathcal{P} \) if it is affine over each of the cells of \( \mathcal{P} \). We introduce the following notation for a continuous piecewise linear function \( \pi \) over \( \mathcal{P} \).

Motivated by Gomory–Johnson’s characterization of minimal valid functions (Theorem 1.1), we are interested in functions \( \pi : \mathbb{R}^k \to \mathbb{R} \) that are periodic modulo \( \mathbb{Z}^k \), i.e., for all \( x \in \mathbb{R}^k \) and all vectors \( t \in \mathbb{Z}^k \), we have \( \pi(x + t) = \pi(x) \). If \( \pi \) is periodic modulo \( \mathbb{Z}^k \) and continuous piecewise linear over a pure and complete complex \( \mathcal{P} \), then we will usually assume that \( \mathcal{P} \) is also periodic modulo \( \mathbb{Z}^k \), i.e., for all \( I \in \mathcal{P} \) and all vectors \( t \in \mathbb{Z}^k \), the translated polyhedron \( I + t \) also is a face of \( \mathcal{P} \).

Remark 3.2 Under these assumptions it is clear that there are various ways to make the description of \( \pi \) finite. For example, \( \tilde{D} := [0, 1)^k \) is a fundamental domain (system of unique representatives) of \( \mathbb{R}^k \) with respect to the natural action of \( \mathbb{Z}^k \), and so it suffices to know the values of \( \pi \) on \( \tilde{D} \). However, it is inconvenient that \( \tilde{D} \) is not closed. On the other hand, if we use instead its closure, \( D := [0, 1]^k \), we lose uniqueness since not every point \( x \in \mathbb{R}^k \) would have a unique decomposition as \( x = d + z \) for some \( d \in D \) and \( z \in \mathbb{Z}^k \). Another viewpoint, considering polyhedral complexes of the torus \( \mathbb{R}^k / \mathbb{Z}^k \), would require more complicated definitions. Thus, in most of this paper,
we find it most convenient and natural to work with periodic functions and infinite periodic complexes.

3.2 The extended complex $\Delta P$

Let $P$ be a pure, complete polyhedral complex of $\mathbb{R}^k$. For any $I, J, K \subseteq \mathbb{R}^k$, we define the set

$$F(I, J, K) = \{(x, y) \in \mathbb{R}^k \times \mathbb{R}^k \mid x \in I, y \in J, x + y \in K\}.$$

In the specific case where $I, J, K$ are polyhedra, $F(I, J, K)$ is also a polyhedron. In order to study the additivity domain of a piecewise linear function over $P$, we define the following family of polyhedra in $\mathbb{R}^k \times \mathbb{R}^k$,

$$\Delta P = \{F(I, J, K) \mid I, J, K \in P\}.$$

First, we present formulas for the projections $p_1, p_2, p_3$ of $F(I, J, K)$, as defined in (4), in terms of $I, J$ and $K$. The proofs of the simpler results of this section can be found in “Proofs of lemmas on polyhedral complexes” section of “Appendix 3”.

**Proposition 3.3** Let $I, J, K \subseteq \mathbb{R}^k$. Then

$$p_1(F(I, J, K)) = (K + (-J)) \cap I,$$

$$p_2(F(I, J, K)) = (K + (-I)) \cap J,$$

$$p_3(F(I, J, K)) = (I + J) \cap K.$$

**Remark 3.4** Note that in general, $p_1(F(I, J, K)) \subsetneq I$, $p_2(F(I, J, K)) \subsetneq J$, and $p_3(F(I, J, K)) \subsetneq K$. Consider $I = [0, 1], J = [0, 1], K = [1.5, 2.5]$. Then $F(I, J, K)$ is the triangle conv$\{(1, 0.5), (1, 1), (0.5, 1)\}$, so $p_1(F(I, J, K)) = [0.5, 1], p_2(F(I, J, K)) = [0.5, 1]$ and $p_3(F(I, J, K)) = [1.5, 2]$.

The next lemma explains the tight relation between $F$ and its projections $p_1(F), p_2(F)$ and $p_3(F)$.

**Lemma 3.5** Let $I, J, K \subseteq \mathbb{R}^k$ and let $F = F(I, J, K)$. Let $I' = p_1(F), J' = p_2(F)$, and $K' = p_3(F)$. Then $F = F(I', J', K')$.

**Proof** By definition of $I', J', K'$ it follows that $I' \subseteq I, J' \subseteq J, K' \subseteq K$. Therefore $F(I', J', K') \subseteq F(I, J, K)$.

Observe that for any $\tilde{F} \subseteq \mathbb{R}^k \times \mathbb{R}^k$ and $(\tilde{x}, \tilde{y}) \in \tilde{F}$, by definition we have $\tilde{x} \in p_1(\tilde{F}), \tilde{y} \in p_2(\tilde{F})$, and $\tilde{x} + \tilde{y} \in p_3(\tilde{F})$. Therefore $(\tilde{x}, \tilde{y}) \in \{(x, y) \mid x \in p_1(\tilde{F}), y \in p_2(\tilde{F}), x + y \in p_3(\tilde{F})\} = F(p_1(\tilde{F}), p_2(\tilde{F}), p_3(\tilde{F}))$. Hence, $\tilde{F} \subseteq F(p_1(\tilde{F}), p_2(\tilde{F}), p_3(\tilde{F}))$. Thus,

$$F(I, J, K) \subseteq F(p_1(F(I, J, K)), p_2(F(I, J, K)), p_3(F(I, J, K))) = F(I', J', K').$$

Therefore, $F(I, J, K) = F(I', J', K')$. $\square$
The next lemma shows that $\Delta P$ is a polyhedral complex, which follows from the fact that $P$ is a polyhedral complex.

**Lemma 3.6** If $P$ is a pure, complete polyhedral complex in $\mathbb{R}^k$, then $\Delta P$ is a pure, complete polyhedral complex in $\mathbb{R}^k \times \mathbb{R}^k$.

Let $\pi$ be a continuous piecewise linear function over $P$. We will study the function $\Delta_1 \pi : \mathbb{R}^k \times \mathbb{R}^k \to \mathbb{R}$, as defined in Lemma 1.4, which measures the slack in the subadditivity constraints.

**Lemma 3.7** $\Delta_1 \pi$ is continuous piecewise linear over $\Delta P$.

**Proof** First, $\Delta_1 \pi$ is continuous since it is the sum of continuous functions. For any $F(I, J, K) \in \Delta P$, $\Delta_1 \pi | F(I, J, K)(x, y) = \pi | I(x) + \pi | J(y) - \pi | K(x + y)$. Since $\pi | I, \pi | J, \pi | K$ are all affine, it follows that $\Delta_1 \pi | F(I, J, K)$ is affine. Therefore $\Delta_1 \pi$ is affine over every face in $\Delta P$, i.e., $\Delta_1 \pi$ continuous piecewise linear over $\Delta P$. 

**Remark 3.8** If $\pi$ and $P$ are periodic modulo $\mathbb{Z}^k$, then $\Delta_1 \pi$ and $\Delta P$ are periodic modulo $\mathbb{Z}^k \times \mathbb{Z}^k$. Indeed, let $F \in \Delta P$, so $F = F(I, J, K)$ for some $I, J, K \in P$. Then for $(u, v) \in \mathbb{Z}^k \times \mathbb{Z}^k$ we have $F + (u, v) = F(I + u, J + v, K + u + v) \in \Delta P$. In order to make the description of $\Delta_1 \pi$ finite, we can choose a fundamental domain (system of unique representatives) of $\mathbb{R}^k \times \mathbb{R}^k$ with respect to the action of $\mathbb{Z}^k \times \mathbb{Z}^k$, for example $\Delta \tilde{D} := [0, 1]^k \times [0, 1]^k$.

**Remark 3.9** We remark that $\Delta_1 \pi(x, y)$ is also invariant under exchanging $x$ and $y$. This can be expressed as an action of the symmetric group $S_2$. Together we obtain the action of the group $\mathbb{Z}^k \wr S_2$, a wreath product, and so we would be able to choose a smaller fundamental domain, corresponding to the action of this group. Thus, in a practical implementation of our algorithms, this allows us to store less information when handling $\Delta_1 \pi$ and hence improve the running time of our algorithms.

### 3.3 Finite test for minimality of piecewise linear functions

By Theorem 1.1, we can test whether a function is minimal by testing subadditivity and the symmetry condition. These properties are easy to test when the function is continuous piecewise linear. The first of such tests came from Gomory and Johnson [19, Theorem 7] for the case $k = 1$. Richard, Li, and Miller [26, Theorem 22] gave a similar superadditivity test for discontinuous piecewise linear functions. In [5], the authors gave a minimality test for discontinuous piecewise linear functions for the $k = 1$ case. In the present paper, we give a similar test for continuous piecewise linear functions for general $k$. As in [5], we do not claim novelty for these ideas. Since our focus of this paper is classifying extreme functions and our theorems only consider minimal functions, we present these minimality tests to give a complete picture.

We assume that the function given to us is periodic and is described by a pure and complete polyhedral complex $P$ where every cell in $P$ is bounded and therefore each

---

3 Note that in [19], the word “minimal” needs to be replaced by “satisfies the symmetry condition” throughout the statement of their theorem and its proof.
cell is the convex hull of its vertices. As we explain in “Boundedness of cells for genuinely \( k \)-dimensional functions” section of the Appendix, the assumption that every cell is bounded is not very restrictive. In particular, we show that every continuous minimal piecewise linear function \( \pi : \mathbb{R}^k \to \mathbb{R} \) that satisfies a certain regularity condition called genuinely \( k \)-dimensional (see Definition B.1) has the property that if \( \mathcal{P} \) is periodic modulo \( \mathbb{Z}^k \), then every cell of \( \mathcal{P} \) is bounded (Lemma B.15). Furthermore, if the function \( \pi \) is not genuinely \( k \)-dimensional, then we can project it into a lower dimension and study it there (Proposition B.9, Remark B.10).

We use \text{vert}(\cdot)\) to denote the set of vertices of a polyhedron or polyhedral complex. For a polyhedral complex \( \mathcal{P} \) in \( \mathbb{R}^k \) and a set \( S \subseteq \mathbb{R}^k \), we define \( S \cap \mathcal{P} := \{ S \cap F \mid F \in \mathcal{P} \} \). When \( S \) is a polyhedron in \( \mathbb{R}^k \), the collection \( S \cap \mathcal{P} \) is again a polyhedral complex. We write \( \mathbf{1} \) to denote the vector with all entries as one, and \( \text{(mod } \mathbf{1} \text{)} \) to denote componentwise equivalence modulo 1.

**Theorem 3.10** (Minimality test) Let \( \mathcal{P} \) be a pure, complete, polyhedral complex in \( \mathbb{R}^k \) that is periodic modulo \( \mathbb{Z}^k \) and every cell of \( \mathcal{P} \) is bounded. Let \( \pi : \mathbb{R}^k \to \mathbb{R} \) be a continuous function that is periodic modulo \( \mathbb{Z}^k \) and that is a piecewise linear function over \( \mathcal{P} \). Let \( \Delta \tilde{D} = [0, 1]^k \times [0, 1]^k \) or another fundamental domain as described in Remarks 3.8 and 3.9. Then \( \pi \) is minimal for \( \mathcal{R}_f(\mathbb{R}^k, \mathbb{Z}^k) \) if and only if the following conditions hold:

1. \( \pi(\mathbf{0}) = 0 \).
2. Subadditivity test: \( \Delta \pi(\mathbf{u}, \mathbf{v}) \geq 0 \) for all \( (\mathbf{u}, \mathbf{v}) \in \Delta \tilde{D} \cap \text{vert}(\Delta \mathcal{P}) \).
3. Symmetry test: \( \pi(\mathbf{f}) = 1 \) and 
   \[
   \Delta \pi(\mathbf{u}, \mathbf{v}) = 0 \text{ for all } (\mathbf{u}, \mathbf{v}) \in \Delta \tilde{D} \cap \text{vert}(\Delta \mathcal{P} \cap \{(\mathbf{u}, \mathbf{v}) \mid \mathbf{u} + \mathbf{v} \equiv \mathbf{f} \text{ (mod } \mathbf{1})\}).
   \]

**Proof** We use the characterization of minimal functions given by Theorem 1.1. Clearly these conditions are necessary. We will show that they are sufficient.

Since every cell of \( \mathcal{P} \) is bounded, the cells of \( \Delta \mathcal{P} \) are also bounded. By Lemma 3.7, \( \Delta \pi \) is continuous piecewise linear over \( \Delta \mathcal{P} \). Therefore \( \Delta \pi \) is completely determined by the values on \( \text{vert}(\Delta \mathcal{P}) \).

Let \( (x, y) \in \mathbb{R}^k \times \mathbb{R}^k \). For subadditivity, we need to show that \( \Delta \pi(x, y) \geq 0 \). Let \( F \in \Delta \mathcal{P} \) be such that \( (x, y) \in F \). Consider any vertex \( (\mathbf{u}, \mathbf{v}) \in \text{vert}(F) \). Since \( \Delta \tilde{D} \) is a fundamental domain for \( \mathbb{Z}^k \times \mathbb{Z}^k \), and \( \Delta \mathcal{P} \) is periodic modulo \( \mathbb{Z}^k \times \mathbb{Z}^k \), there exists a point \( (w, z) \in \mathbb{Z}^k \times \mathbb{Z}^k \) such that \( (\mathbf{u} + w, \mathbf{v} + z) \in \Delta \tilde{D} \cap \text{vert}(\Delta \mathcal{P}) \). Since \( \Delta \pi \) is periodic modulo \( \mathbb{Z}^k \times \mathbb{Z}^k \) and is nonnegative on \( (\mathbf{u} + w, \mathbf{v} + z) \), we have that \( \Delta \pi \) is also nonnegative on \( (\mathbf{u}, \mathbf{v}) \). Therefore \( \Delta \pi \) is nonnegative on all of \( \text{vert}(F) \), and since \( \Delta \pi|_{F} \) is affine, by convexity it follows that \( \Delta \pi(x, y) \geq 0 \). Therefore \( \pi \) is subadditive.

Similarly, to show symmetry, we need to show that \( \Delta \pi(x, y) = 0 \) for all \( x, y \in \mathbb{R}^k \) such that \( x + y \equiv \mathbf{f} \text{ (mod } \mathbf{1}) \). Observe that \( \Delta \mathcal{P} \cap \{(\mathbf{u}, \mathbf{v}) \mid \mathbf{u} + \mathbf{v} \equiv \mathbf{f} \text{ (mod } \mathbf{1})\} \) is a polyhedral complex. Let \( (x, y) \in \mathbb{R}^k \) such that \( x + y \equiv \mathbf{f} \text{ (mod } \mathbf{1}) \). By letting \( F \in \Delta \mathcal{P} \cap \{(\mathbf{u}, \mathbf{v}) \mid \mathbf{u} + \mathbf{v} \equiv \mathbf{f} \text{ (mod } \mathbf{1})\} \) such that \( (x, y) \in F \), the same argument as above shows that \( \Delta \pi = 0 \) for all vertices of \( F \), and by convexity, \( \Delta \pi|_{F} = 0 \). Therefore \( \Delta \pi(x, y) = 0 \) and we conclude that \( \pi \) is symmetric.

Finally, we show that \( \pi \) is nonnegative. First, since \( \pi \) is continuous on the compact set \( [0, 1]^k \), and is periodic, \( \pi \) is bounded. Suppose for the sake of contradiction that
\( \pi(x) < 0 \) for some \( x \neq 0 \). Since \( \pi \) is subadditive, \( \pi(nx) \leq n\pi(x) \). But since \( n\pi(x) \to -\infty \) as \( n \to \infty \), this shows that \( \pi \) is unbounded, which is a contradiction. \( \Box \)

Remark 3.11 (Symmetry test simplified) Suppose \( \mathcal{P} \) is pure, complete polyhedral complex that is periodic modulo \( \mathbb{Z}^k \) and contains \( \{f\} \in \mathcal{P} \). Then \( \Delta\tilde{D} \cap \text{vert}(\Delta\mathcal{P} \cap \{(u, v) \mid u + v \equiv f \pmod{1}\}) \subseteq \Delta\tilde{D} \cap \text{vert}(\Delta\mathcal{P}) \). In particular, the symmetry test (3 in Theorem 3.10) then reduces to checking on vertices \( (u, v) \in \Delta\tilde{D} \) of \( \Delta\mathcal{P} \) such that \( u + v \equiv f \pmod{1} \).

To see this, consider any face \( F(I, J, K) \in \Delta\mathcal{P} \), where \( I, J, K \in \mathcal{P} \), and any \( z \in \mathbb{Z}^k \). Then \( F(I, J, K) \cap \{(x, y) \in \mathbb{R}^k \times \mathbb{R}^k \mid x + y = f + z\} = F(I, J, \{f + z\} \cap K) \). Since \( \mathcal{P} \) is periodic modulo \( \mathbb{Z}^k \) and \( \{f\} \in \mathcal{P} \), we have \( \{f + z\} \in \mathcal{P} \). Since \( \mathcal{P} \) is a polyhedral complex, \( \{f + z\} \cap K \in \mathcal{P} \). Therefore, \( F(I, J, \{f + z\} \cap K) \in \Delta\mathcal{P} \). Therefore, \( \text{vert}(\Delta\mathcal{P} \cap \{(u, v) \mid u + v \equiv f \pmod{1}\}) \subseteq \text{vert}(\Delta\mathcal{P}) \). Intersecting both sides with \( \Delta\tilde{D} \) maintains the containment relationship.

3.4 Combinatorializing the additivity domain

Let \( \pi : \mathbb{R}^k \to \mathbb{R} \) be a continuous piecewise linear function over a pure, complete polyhedral complex \( \mathcal{P} \). Recall the definition of the additivity domain of \( \pi \),

\[
E(\pi) = \{(x, y) \mid \Delta\pi(x, y) = 0\}.
\]

We now give a combinatorial representation of this set using the faces of \( \mathcal{P} \); this extends a technique in [5]. Let

\[
E(\pi, \mathcal{P}) = \{F \in \Delta\mathcal{P} \mid \Delta\pi|_F = 0\}.
\]

We consider \( E(\pi, \mathcal{P}) \) to include \( F = \emptyset \), on which \( \Delta\pi|_F = 0 \) holds trivially. Then \( E(\pi, \mathcal{P}) \) is another polyhedral complex, a subcomplex of \( \Delta\mathcal{P} \). As mentioned, if \( \pi \) is continuous, then \( \Delta\pi \) is continuous. Under this continuity assumption, we can consider only the set of maximal faces in \( E(\pi, \mathcal{P}) \). We define

\[
E_{\text{max}}(\pi, \mathcal{P}) = \{F \in E(\pi, \mathcal{P}) \mid F \text{ is a maximal face by set inclusion in } E(\pi, \mathcal{P})\}.
\]

Lemma 3.12 Suppose that \( \pi \) is subadditive. Then

\[
E(\pi) = \bigcup\{F \in E(\pi, \mathcal{P})\} = \bigcup\{F \in E_{\text{max}}(\pi, \mathcal{P})\}.
\]

Proof Clearly \( E(\pi) \supseteq \bigcup\{F \in E(\pi, \mathcal{P})\} \supseteq \bigcup\{F \in E_{\text{max}}(\pi, \mathcal{P})\} \). We show the reverse inclusions. Suppose \( (x, y) \in E(\pi) \). Since \( \Delta\mathcal{P} \) is a polyhedral complex that covers all of \( \mathbb{R}^k \times \mathbb{R}^k \), there exists a face \( F \in \Delta\mathcal{P} \) such that \( (x, y) \in \text{rel int}(F) \). Note that if \( (x, y) \in \text{vert}(\Delta\mathcal{P}) \), then \( F = \{(x, y)\} \) is 0-dimensional face of \( \Delta\mathcal{P} \). Suppose that \( (x, y) \notin \text{vert}(\Delta\mathcal{P}) \). Since \( \pi \) is subadditive, \( \Delta\pi \geq 0 \). Further, since \( \Delta\pi \) is affine in \( F \), \( (x, y) \in \text{rel int}(F) \), and \( \Delta\pi(x, y) = 0 \), we have that \( \Delta\pi|_F = 0 \). Therefore,
$F \in E(\pi, \mathcal{P})$ and $(x, y) \in F$ is contained in the first right hand side. Clearly, if $F$ is not maximal in $E(\pi, \mathcal{P})$, then it is contained in a maximal face $F' \in E_{\max}(\pi, \mathcal{P})$, and hence the reverse inclusions also hold. □

This combinatorial representation can then be made finite by choosing representatives under the action of $\mathbb{Z}^k \times \mathbb{Z}^k$, which leaves $E(\pi)$ and thus $E(\pi, \mathcal{P})$ and $E_{\max}(\pi, \mathcal{P})$ invariant, as in Remark 3.8.

### 3.5 Non-extremality via perturbation functions

We now give a method of showing $\pi$ is not extreme when we are given a certain piecewise linear perturbation function $\tilde{\pi}$.

**Theorem 3.13** (Perturbation) Let $\mathcal{P}$ be a pure, complete, polyhedral complex in $\mathbb{R}^k$ that is periodic modulo $\mathbb{Z}^k$ and every cell of $\mathcal{P}$ is bounded. Suppose $\pi$ is minimal and continuous piecewise linear over $\mathcal{P}$. Suppose $\tilde{\pi} \neq 0$ is continuous piecewise linear over $\mathcal{P}$, is periodic modulo $\mathbb{Z}^k$ and satisfies $E(\pi) \subseteq E(\tilde{\pi})$ and $\tilde{\pi}(f) = 0$. Then $\pi$ is not extreme. Furthermore, given $\tilde{\pi}$, there exists an $\epsilon > 0$ such that $\pi^1 = \pi + \epsilon \tilde{\pi}$ and $\pi^2 = \pi - \epsilon \tilde{\pi}$ are distinct minimal functions that are continuous piecewise linear over $\mathcal{P}$ such that $\pi = \frac{1}{2}(\pi^1 + \pi^2)$.

**Proof** Let $\Delta \tilde{D} = [0, 1]^k \times [0, 1]^k$ (or any other fundamental domain as in Remarks 3.8 and 3.9). Let

$$
eq 1 \min(\Delta \pi(x, y) \mid (x, y) \in \Delta \tilde{D} \cap \text{vert}(\Delta \mathcal{P}), \Delta \pi(x, y) \neq 0) \over 2 \max(|\Delta \tilde{\pi}(u, v)| \mid (u, v) \in \Delta \tilde{D} \cap \text{vert}(\Delta \mathcal{P}), \Delta \tilde{\pi}(u, v) \neq 0).$$

Note that $\epsilon$ exists and $\epsilon > 0$ since $\Delta \pi$ and $\Delta \tilde{\pi}$ are non-zero somewhere, $\Delta \pi$ is a nonnegative function because $\pi$ is minimal, and $\text{vert}(\Delta \mathcal{P}) \neq \emptyset$ since $\Delta \mathcal{P}$ is a collection of bounded polyhedra.

Setting $\pi^1 = \pi + \epsilon \tilde{\pi}, \pi^2 = \pi - \epsilon \tilde{\pi}$, we see that $\pi^1, \pi^2$ are piecewise linear and periodic modulo $\mathbb{Z}^k$. We show that $\pi^1, \pi^2$ satisfy conditions (1), (2), and (3) of Theorem 3.10 to show that $\pi^1, \pi^2$ are minimal functions. Since $\epsilon > 0$ and $\tilde{\pi} \neq 0$, $\pi^1, \pi^2$ are then distinct minimal functions that show that $\pi$ is not extreme.

We use the assumption that $E(\pi) \subseteq E(\tilde{\pi})$, which implies that $\Delta \tilde{\pi}(x, y) = 0$ whenever $\Delta \pi(x, y) = 0$.

First, $\Delta \pi(0, 0) = \pi(0) + \pi(0) - \pi(0) = \pi(0) = 0$, therefore $0 = \Delta \tilde{\pi}(0, 0) = \tilde{\pi}(0)$. Therefore $\pi^1(0) = \pi^2(0) = 0$. Since $\tilde{\pi}(f) = 0$ and $\pi(f) = 1$, it follows that $\pi^1(f) = \pi^2(f) = 1$. These results along with $E(\pi) \subseteq E(\tilde{\pi})$ satisfy conditions (1) and (3) and Theorem 3.10.

Next, for any $(x, y) \in \Delta \tilde{D} \cap \text{vert}(\Delta \mathcal{P})$, from the definition of $\epsilon$ and the fact that $E(\pi) \subseteq E(\tilde{\pi})$, which implies that $\Delta \tilde{\pi}(x, y) = 0$ whenever $\Delta \pi(x, y) = 0$, we have

$$\Delta \pi(x, y) + \epsilon \Delta \tilde{\pi}(x, y) \geq \Delta \pi(x, y) - \epsilon |\Delta \tilde{\pi}(x, y)| \geq \frac{1}{2} \Delta \pi(x, y) \geq 0.$$

Therefore $\pi^1, \pi^2$ satisfy also condition (2) of Theorem 3.10, and we are done. □
4 A class of minimal valid functions defined over $\mathbb{R}^2$

We now define the class of *diagonally constrained* functions $\pi : \mathbb{R}^2 \rightarrow \mathbb{R}$. We first introduce a special two-dimensional polyhedral complex. The functions will be continuous piecewise linear over this complex.

4.1 The standard triangulations $\mathcal{P}_q$ of $\mathbb{R}^2$ and their geometry

Let $q$ be a positive integer. Consider the arrangement $\mathcal{H}_q$ of all hyperplanes (lines) of $\mathbb{R}^2$ of the form $(0\ 1) \cdot x = b$, $(1\ 0) \cdot x = b$, and $(1\ 1) \cdot x = b$, where $b \in 1/q\mathbb{Z}$. The complement of the arrangement $\mathcal{H}_q$ consists of two-dimensional cells, whose closures are the triangles

$$0\square = \frac{1}{q} \text{conv} \left(\{(0,0), (0,1), (1,0)\}\right)$$

and their translates by elements of the lattice $1/q\mathbb{Z}^2$. We denote by $\mathcal{P}_q$ the collection of these triangles and the vertices and edges that arise as intersections of the triangles, and the empty set. Thus $\mathcal{P}_q$ is a locally finite polyhedral complex that is periodic modulo $\mathbb{Z}^2$. Since all nonempty faces of $\mathcal{P}_q$ are simplices, it is a triangulation of the space $\mathbb{R}^2$.

**Example 4.1** Figure 2, which appeared in the introduction, shows the complex $\mathcal{P}_5$ with an example of a minimal valid continuous piecewise linear function on $\mathcal{P}_5$ with $f = (2/5, 2/5)$ that is periodic modulo $\mathbb{Z}^2$. The function is uniquely determined by its values on the vertices of $\mathcal{P}_5$ that lie within the fundamental domain $\tilde{D} = [0, 1)^2$. Note that, due the periodicity of the function modulo $\mathbb{Z}^2$, the values of the function on the left and the right edge (and likewise on the bottom and the top edge) of $D = [0, 1]^2$ match.

There is a partial ordering structure on the family of triangulations $\mathcal{P}_q$, whose importance to us will become clear later: For every $m > 1$, the triangulation $\mathcal{P}_{mq}$ is a subtriangulation (refinement) of $\mathcal{P}_q$, i.e., every face of $\mathcal{P}_q$ is a union of faces of $\mathcal{P}_{mq}$.

Within the polyhedral complex $\mathcal{P}_q$, let $\mathcal{P}_{q,\square}$ be the set of 0-faces (vertices), $\mathcal{P}_{q,\square}$ be the set of 1-faces (edges), and $\mathcal{P}_{q,\square}$ be the set of 2-faces (triangles). The sets of diagonal, vertical, and horizontal edges will be denoted by $\mathcal{P}_{q,\square}$, $\mathcal{P}_{q,\square}$, and $\mathcal{P}_{q,\square}$, respectively. We also use abbreviations such as $\mathcal{P}_{q,\square} = \mathcal{P}_{q,\square} \cup \mathcal{P}_{q,\square}$, $\mathcal{P}_{q,\square} = \mathcal{P}_{q,\square} \cup \mathcal{P}_{q,\square} \cup \mathcal{P}_{q,\square}$, etc.

**Remark 4.2** Let

$$A = \begin{bmatrix} 1 & -1 & 0 & 0 & 1 & -1 \end{bmatrix}^T.$$

Then for every face $I \in \mathcal{P}_q$, there exists a vector $b \in 1/q\mathbb{Z}^6$ such that $I = \{x \mid Ax \leq b\}$. Furthermore, for every vector $b \in 1/q\mathbb{Z}^6$, the set $\{x \mid Ax \leq b\}$ is a union of faces of $\mathcal{P}_q$ (possibly empty), since each inequality corresponds to a hyperplane in the arrangement $\mathcal{H}_q$.

 Springer
The matrix $A$ is totally unimodular. Thus the specific choice of the triangulation $\mathcal{P}_q$ lends itself to strong unimodularity properties that reveal structure in the complex. More importantly, they allow us to develop a simple theory of extremality, in which all relevant properties of the function can be expressed using the faces of the original complex $\mathcal{P}_q$.

The following lemma can be shown by enumerating cases and using simple 2-dimensional geometry. We give an alternate proof that utilizes the total unimodularity of $A$ and avoids case analysis.

**Lemma 4.3** Let $I, J \in \mathcal{P}_q$. Then $-I$ and $I + J$ are unions of faces in $\mathcal{P}_q$.

**Proof** If $I = \{ \mathbf{x} \in \mathbb{R}^2 \mid \mathbf{A}\mathbf{x} \preceq \mathbf{b} \}$ for some $\mathbf{b} \in \frac{1}{q} \mathbb{Z}^6$, then $-I = \{ \mathbf{x} \in \mathbb{R}^2 \mid -\mathbf{A}\mathbf{x} \preceq \mathbf{b} \}$. Since $-A$ has the same rows as $A$ (with a permutation), by Remark 4.2, $-I$ is a union of faces of $\mathcal{P}_q$.

We now show that the Minkowski sum $I + J$ is a union of faces in $\mathcal{P}_q$.

Let $\mathbf{a}_i$ be the $i$th row vector of $A$. Then there exist vectors $\mathbf{b}_1, \mathbf{b}_2$ such that $I = \{ \mathbf{x} \mid \mathbf{A}\mathbf{x} \preceq \mathbf{b}_1 \}$, $J = \{ \mathbf{y} \mid \mathbf{A}\mathbf{y} \preceq \mathbf{b}_2 \}$. Moreover, due to the total unimodularity of the matrix $A$, the right-hand side vectors $\mathbf{b}_1, \mathbf{b}_2$ can be chosen so that $\mathbf{b}_1, \mathbf{b}_2$ are tight, i.e.,

$$\max_{\mathbf{x} \in I} \mathbf{a}_i \cdot \mathbf{x} = \mathbf{b}_1^i, \quad \max_{\mathbf{y} \in J} \mathbf{a}_i \cdot \mathbf{y} = \mathbf{b}_2^i, \quad (9)$$

and $\mathbf{b}_1, \mathbf{b}_2 \in \frac{1}{q} \mathbb{Z}^6$.

We claim that $I + J = \{ \mathbf{x} \mid \mathbf{A}\mathbf{x} \preceq \mathbf{b}_1 + \mathbf{b}_2 \}$. Clearly $I + J \subseteq \{ \mathbf{x} \mid \mathbf{A}\mathbf{x} \preceq \mathbf{b}_1 + \mathbf{b}_2 \}$. We show the reverse direction. Let $K'$ be a facet (edge) of $I + J$. Then $K' = I' + J'$, where $I'$ is a face of $I$ and $J'$ is a face of $J$. Without loss of generality, assume that $I'$ is an edge; then $J'$ is either a vertex or an edge. By well-known properties of Minkowski sums, the normal cone of $K'$ is the intersection of the normal cones of $I'$ in $I$ and $J'$ in $J$. Thus $K'$ has the same normal direction as the facet (edge) $I'$. (This argument relied on the fact that we are in dimension two.) This proves that $I + J = \{ \mathbf{x} \mid \mathbf{A}\mathbf{x} \preceq \mathbf{b} \}$ for some vector $\mathbf{b}$.

Let $\mathbf{x}^*, \mathbf{y}^*$ be maximizers in (9). Then $\mathbf{x}^* + \mathbf{y}^* \in I + J$, and thus

$$\mathbf{b}_1^i + \mathbf{b}_2^i = \mathbf{a}_i \cdot \mathbf{x}^* + \mathbf{a}_i \cdot \mathbf{y}^* \leq \max_{\mathbf{z} \in I + J} \mathbf{a}_i \cdot \mathbf{z} \leq \max_{\mathbf{x} \in I} \mathbf{a}_i \cdot \mathbf{x} + \max_{\mathbf{y} \in J} \mathbf{a}_i \cdot \mathbf{y} = \mathbf{b}_1^i + \mathbf{b}_2^i.$$

Therefore, $\max_{\mathbf{z} \in I + J} \mathbf{a}_i \cdot \mathbf{z} = \mathbf{b}_1^i + \mathbf{b}_2^i$, which shows that every constraint $\mathbf{a}_i \cdot \mathbf{z} \leq \mathbf{b}_1^i$ is met at equality, and therefore $I + J = \{ \mathbf{x} \mid \mathbf{A}\mathbf{x} \preceq \mathbf{b}_1 + \mathbf{b}_2 \}$ and we conclude that $I + J$ is a union of subsets in $\mathcal{P}_q$. \hfill $\square$

This result has an important consequence for the complex $\Delta \mathcal{P}_q$, allowing component projections of the faces of $\Delta \mathcal{P}_q$ to be faces of $\mathcal{P}_q$.

**Lemma 4.4** (i) Let $F \in \Delta \mathcal{P}_q$. Then the projections $p_1(F), p_2(F),$ and $p_3(F)$ are faces in the complex $\mathcal{P}_q$.

(ii) In particular, let $(\mathbf{x}, \mathbf{y})$ be a vertex of $\Delta \mathcal{P}_q$. Then $\mathbf{x}, \mathbf{y}$ are vertices of the complex $\mathcal{P}_q$, i.e., $\mathbf{x}, \mathbf{y} \in \frac{1}{q} \mathbb{Z}^2$. 

Springer
Proof. By definition of $\Delta P_q$, there exist $I, J, K \in P_q$ such that $F = F(I, J, K)$. Let $I' = p_1(F)$, $J' = p_2(F)$, and $K' = p_3(F)$. By Proposition 3.3,

$$I' = p_1(F) = (K + (-J)) \cap I,$$
$$J' = p_2(F) = (K + (-I)) \cap J,$$
$$K' = p_3(F) = (I + J) \cap K,$$

and thus, by Lemma 4.3, $I'$, $J'$, and $K'$ are faces of $P_q$. 

**Theorem 4.5** (Simplified minimality test) Let $\pi : \mathbb{R}^2 \to \mathbb{R}$ be a continuous piecewise linear function over $P_q$ that is periodic modulo $\mathbb{Z}^2$. Suppose $f \in \text{vert}(P_q)$. Then $\pi$ is minimal for $R_f(\mathbb{R}^2, \mathbb{Z}^2)$ if and only if the following conditions hold.

1. $\pi(0) = 0$.
2. Subadditivity test: $\pi(x) + \pi(y) \geq \pi(x+y)$ for all $x, y \in \frac{1}{q} \mathbb{Z}^2 \cap [0, 1)^2$.
3. Symmetry test: $\pi(x) + \pi(f-x) = 1$ for all $x \in \frac{1}{q} \mathbb{Z}^2 \cap [0, 1)^2$.

*Proof.* Since $\{f\} \in P_q$, the result follows by applying Theorem 3.10 with $\Delta D = [0, 1)^2 \times [0, 1)^2$ and using Remark 3.11 and Lemma 4.4 to show that the vertices that need to be considered are vertices $(x, y) \in \frac{1}{q} \mathbb{Z}^2 \times \frac{1}{q} \mathbb{Z}^2 \cap \Delta D$.

**Example 4.6** (Example 4.1, continued) We now visualize the additive faces $F \in E(\pi, P_q)$ (Fig. 2); following Lemma 3.12, we are particularly interested in the maximal additive faces $\tilde{F} \in E_{\text{max}}(\pi, P_q)$. Following Remark 3.8, $E(\pi, P_q)$ is invariant under the action of $\mathbb{Z}^k \times \mathbb{Z}^k$. By the construction of $P_q$, we can always choose a representative $\tilde{F} \in E_{\text{max}}(\pi, P_q)$ that is a subset of the closure $\Delta D = [0, 1]^2 \times [0, 1]^2$ of the fundamental domain. Then all faces $F \in E(\pi, P_q)$ with $F \subseteq \tilde{F}$ also are subsets of $\Delta D$.

By Lemma 3.5, each $F \in E(\pi, P_q)$ is determined by its projections $I = p_1(F)$, $J = p_2(F)$, $K = p_3(F)$ as $F = F(I, J, K)$. Due to the choice of triangulation $P_q$, by Lemma 4.4, $I, J, K$ are faces of $P_q$. When $F \subseteq \Delta D = [0, 1]^2 \times [0, 1]^2$, we have $I, J \subseteq D = [0, 1]^2$ and $K \subseteq 2D = [0, 2]^2$.

Thus we can visualize faces $F \subseteq \Delta D$ by showing three diagrams, corresponding to its projections $p_i(F) \in P_q$, where $p_1(F)$, $p_2(F) \subseteq D$ and $p_3(F) \subseteq 2D$ as follows. For example, consider the face $\tilde{F}$ with

$$p_1(\tilde{F}) = \begin{array}{c|cccc} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ \end{array}, \quad p_2(\tilde{F}) = \begin{array}{c|cccc} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ \end{array}, \quad p_3(\tilde{F}) = \begin{array}{c|cccc} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ \end{array}.$$

It is a maximal additive face. It has of course many smaller included faces, for example $F$ given by

$$p_1(F) = \begin{array}{c|cccc} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ \end{array}, \quad p_2(F) = \begin{array}{c|cccc} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ \end{array}, \quad p_3(F) = \begin{array}{c|cccc} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ \end{array}.$$
Here, $p_1(F) \in \mathcal{P}_{q_{\pi}}$, $p_2(F) \in \mathcal{P}_{q_{\pi}}$, and $p_3(F) \in \mathcal{P}_{q_{\pi}}$.

Since $\pi$ is a minimal valid function, the symmetry condition implies that for any face $I \in \mathcal{P}_{q}$, we have $F(I, f - I, \{f\}) \in E(\pi, \mathcal{P}_{q})$; but these are not necessarily maximal additive faces, even when $I \in \mathcal{P}_{q_{\pi}}$. We illustrate this in Fig. 5, which shows a face $F = F(I, f - I, \{f\})$ with $I = p_1(F) \in \mathcal{P}_{q_{\pi}}$ with a containing maximal additive face $\bar{F}$ and the poset of the faces of $F$.

Table 1 shows all maximal additive faces $F \in E_{\text{max}}(\pi, \mathcal{P}_{q})$ after all the faces arising from the symmetry condition have been removed. Following Remark 3.9, $F(I, J, K) \in E_{\text{max}}(\pi, \mathcal{P}_{q})$ if and only if $F(J, I, K) \in E_{\text{max}}(\pi, \mathcal{P}_{q})$, so we have also removed the redundancy of swapping $I$ and $J$ by choosing either one of the two representatives arbitrarily.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{Fig5.png}
\caption{A non-maximal additive face $F \in E(\pi, \mathcal{P}_{q})$ corresponding to a symmetry relation, the poset of its faces, and a maximal additive face $\bar{F} \in E_{\text{max}}(\pi, \mathcal{P}_{q})$ with $F \subset \bar{F}$. The triangles in these diagrams are colored yellow, matching Fig. 2, while points and edges are colored red. This figure reveals that there are many additive faces $F \in E(\pi, \mathcal{P}_{q})$ that do not appear in $E_{\text{max}}(\pi, \mathcal{P}_{q})$ and hence are not recorded in Table 1. Furthermore, notice that face $F_1$, with its projections described above, is not a valid maximal additive face for a diagonally constrained function. This diagram explains that $F_1$ is not maximal in $E(\pi, \mathcal{P}_{q})$, and hence does not contradict the fact that $\pi$ is diagonally constrained (color figure online).}
\end{figure}

\[\text{Springer}\]
4.2 Diagonally constrained functions on $\mathcal{P}_q$

Figure 6 (on the right) shows a hierarchy of minimal valid functions $\pi$ depending on the type of the possible projections $p_i(F)$ for maximal additive faces $F \in E_{\text{max}}(\pi, \mathcal{P}_q)$. The labeling of the class is meant to be self-explanatory in Fig. 6; for example, in the lowest class “full-dimensionally constrained”, all projections are 2-dimensional (triangles), in the class “full-dimensionally and point constrained”, the projections are either 2-dimensional (triangles) or 0-dimensional (points), in the class “full-dimensionally, horizontally and point constrained” means the projections are either triangles, or horizontal edges, or points.

In this paper, we study the family of minimal valid functions that allows for two types of degenerations of the maximal additive faces, and characterize (in the sense of Theorems 1.8 and 1.9) the extreme functions within this family. Specifically, we assume that the maximal additive faces $F \in E_{\text{max}}(\pi, \mathcal{P}_q)$ are so that its projections $p_i(F)$ are either full-dimensional (triangles □), points (●), or diagonal edges (■), but not horizontal or vertical edges. These full-dimensionally, diagonally, and point constrained minimal valid functions (Fig. 6) will be called 

**Definition 4.7** A continuous piecewise linear function $\pi$ on $\mathcal{P}_q$ is called *diagonally constrained* if whenever $F \in E_{\text{max}}(\pi, \mathcal{P}_q)$, then $p_i(F) \in \mathcal{P}_q$, $\square\text{X}X\square$ for $i = 1, 2, 3$. 
Table 1 All maximal faces \( F \in E_{\text{max}}(\pi, P) \) of the function \( \pi \) from Example 4.1, except for the faces corresponding to the symmetry condition

| \( p_1(F) \) | \( p_2(F) \) | \( p_3(F) \) | \( p_1(F) \) | \( p_2(F) \) | \( p_3(F) \) |
|----------------|----------------|----------------|----------------|----------------|----------------|
| Three triangles (Type 2) |
| ![Diagram](image1) | ![Diagram](image2) | ![Diagram](image3) | ![Diagram](image4) | ![Diagram](image5) | ![Diagram](image6) |
| Two triangles, one edge (Type 4) |
| ![Diagram](image7) | ![Diagram](image8) | ![Diagram](image9) | ![Diagram](image10) | ![Diagram](image11) | ![Diagram](image12) |
| Three points (Type 1) |
| ![Diagram](image13) | ![Diagram](image14) | ![Diagram](image15) |

The triangles in these diagrams are colored to match Fig. 2, while points and edges are just colored red. Type numbers refer to Lemma 4.9. Notice that none of the light green triangles, for instance, the triangle with vertices \( (\frac{1}{5}, 0), (\frac{1}{5}, \frac{2}{5}), (\frac{2}{5}, 0) \) appear in the table below. This is because the only additive relations these triangles satisfy are from the symmetry condition, which we do not list below.

There are many examples of diagonally constrained functions. The unimodular properties of \( \Delta P \) provide an easy method to compute \( E(\pi, P) \) and test if a function is diagonally constrained by using simple arithmetic and set membership operations on vertices of \( P \); see [20] for details. This can be done in polynomial time in \( q \).
Example 4.8 (Example 4.1, continued) Since no relation appearing in the list of all maximal additive faces (Table 1) involve a vertical or horizontal edge, the function is diagonally constrained. Note that there are relations derived from two triangles and one diagonal edge. These relations create affine properties as described in Fig. 3 (b), and makes the analysis of this function more complicated than full-dimensionally constrained functions.

The following lemma characterizes the types of possible maximal additive faces that can exist for a valid function that is diagonally constrained.

Lemma 4.9 Suppose $\pi$ is continuous piecewise linear over $\mathcal{P}_q$ and is diagonally constrained. Suppose that $F \in E_{\text{max}}(\pi, \mathcal{P}_q)$. Let $I = p_1(F), J = p_2(F), K = p_3(F)$. Then one of the following is true.

(Type 1) $I, J, K \in \mathcal{P}_q, \mathbb{N}$.

(Type 2) $I, J, K \in \mathcal{P}_q, \mathbb{N}$.

(Type 3) One of $I, J, K$ is in $\mathcal{P}_q, \mathbb{N}$ while the other two are in $\mathcal{P}_q, \mathbb{N}$.

(Type 4) One of $I, J, K$ is in $\mathcal{P}_q, \mathbb{N}$ while the other two are in $\mathcal{P}_q, \mathbb{N}$.

All of these types of maximal additive faces appear in the function from Example 4.8: Maximal faces corresponding to the symmetry condition are of Type 3, whereas Types 1, 2, and 4 appear in Table 1.

Proof By definition of diagonally constrained functions, $I, J, K \in \mathcal{P}_q, \mathbb{N} \cup \mathcal{P}_q, \mathbb{N} \cup \mathcal{P}_q, \mathbb{N}$. Elementary counting reveals that there are 27 possible ways to put $I, J, K$ into those three sets, whereas 15 possibilities are described above. We will show that the 12 remaining cases not listed above are not possible because $I, J, K$ are projections of $F$.

1. Suppose $I, J \in \mathcal{P}_q, \mathbb{N}, K \in \mathcal{P}_q, \mathbb{N}$. By Proposition 3.3, $K \subseteq I + J$. But this is not possible because $I + J$ is one-dimensional while $K$ is two-dimensional.

2. Suppose $I, K \in \mathcal{P}_q, \mathbb{N}, J \in \mathcal{P}_q, \mathbb{N}$. By Proposition 3.3, $J \subseteq K + (-I)$. But again, this is not possible because $K + (-I)$ is one-dimensional while $J$ is two-dimensional.

3. Suppose $J, K \in \mathcal{P}_q, \mathbb{N}, I \in \mathcal{P}_q, \mathbb{N}$. This is similar to the last case.

į \hspace{1cm} \Box

4.3 Affine properties of $\pi^i$ on projections of faces in $E(\pi, \mathcal{P}_q)$

Let $\pi$ be a minimal valid function that is continuous piecewise linear over $\mathcal{P}_q$. The lemmas of this subsection will be used to deduce affine properties of valid functions $\pi^1, \pi^2$ when $\pi = \frac{1}{2}(\pi^1 + \pi^2)$ by using Lemma 1.4. Here we will apply Corollary 2.14 to conclude affine properties on faces of $\mathcal{P}_q$. By using Corollary 2.14, we are using the continuity of the function to extend affine properties to the boundaries of faces.

Lemma 4.10 Suppose $\theta: \mathbb{R}^2 \rightarrow \mathbb{R}$ is a continuous function and let $F \in E(\theta, \mathcal{P}_q)$ such that $p_i(F) \in \mathcal{P}_q, \mathbb{N}$ for $i = 1, 2, 3$. Then $\theta$ is affine in $p_i(F)$ for $i = 1, 2, 3$ with the same gradient.
Proof We apply Corollary 2.14 to $F$ with $f, g, h = \theta$ and $L = \mathbb{R}^2$. Since $p_1(F), p_2(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$, and triangles are two-dimensional objects, we have $L \times L + F \subseteq \text{aff}(F)$. The conclusion of the corollary then says that $\theta$ is affine over $p_i(F)$ for $i = 1, 2, 3$ with the same gradient.

Lemma 4.11 Let $\theta : \mathbb{R}^2 \to \mathbb{R}$ be a continuous function. Let $F \in E(\theta, \mathcal{P}_q)$ such that $p_1(F), p_2(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$ and $p_3(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$ (resp., $p_1(F), p_3(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$ and $p_2(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$). Let $L$ be the linear space such that $\text{aff}(p_3(F))$ (resp., $\text{aff}(p_2(F))$) is a translate of $L$. Then for some $c \in \mathbb{R}^2$, $\theta$ is affine with respect to $L$ over $p_1(F), p_2(F), p_3(F)$ with the gradient $c$.

Proof We only give the proof for $p_1(F), p_2(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$ and $p_3(F) \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$. The other case is similar.

Consider any $(u^1, v^1), (u^2, v^2) \in \text{rel int}(F)$. By applying Corollary 2.14 with $F$ and $L$ we see that there exist vectors $c^1, c^2 \in \mathbb{R}^k$ such that $\theta$ is affine with gradient $c^i$ over $(u^i + L) \cap p_1(F), (v^i + L) \cap p_2(F)$ and $(u^i + v^i + L) \cap p_3(F)$ for $i = 1, 2$. Let $\bar{c}^1, \bar{c}^2$ be the orthogonal projections of $c^1$ and $c^2$, respectively, onto the linear space $L$. Therefore, $\theta$ is affine with gradient $\bar{c}^i$ over $(u^i + L) \cap p_1(F), (v^i + L) \cap p_2(F)$ and $(u^i + v^i + L) \cap p_3(F)$ for $i = 1, 2, 3$. Then, since $(u^1 + v^1 + L) \cap p_3(F) = (u^2 + v^2 + L) \cap p_3(F) = p_3(F)$, we have $\bar{c}^1 = \bar{c}^2 = c$. Therefore, we obtain that $\theta$ is affine with respect to $L$ with gradient $c = \bar{c}^1 = \bar{c}^2$ over $p_i(F)$ for $i = 1, 2, 3$.

Definition 4.12 Define

$$L_N = \{x \in \mathbb{R}^2 \mid 1 \cdot x = 0\} = \{\lambda \begin{pmatrix} -1 \\ 1 \end{pmatrix} \mid \lambda \in \mathbb{R}\}.$$}

Lemma 4.13 (Geometric adjacent transference) Let $I, J \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$ be triangles such that $I \cap J \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$. Let $\pi$ be a continuous function defined on $I \cup J$ satisfying the following properties:

(i) $\pi$ is affine on $I$.

(ii) $\pi$ is affine with respect to the linear space $L_N$ (the diagonal direction) on $J$.

Then $\pi$ is affine on $J$.

Proof Let $e = I \cap J \in \mathcal{P}_q\mathcal{S}_q\mathcal{S}_q$ be the common edge of $I$ and $J$. We assume that $e$ is vertical (the argument for horizontal edges is exactly the same) and let $v^0 \in \mathbb{R}^2$ be the vertex of $e$ such that the other vertex is $v^0 + \begin{pmatrix} 0 \\ 1/q \end{pmatrix}$. Since $\pi$ is affine with respect to the linear space $L_N$ on $J$, there exists $c \in \mathbb{R}$ such that $\pi(\begin{pmatrix} x + \lambda \begin{pmatrix} -1 \\ 1 \end{pmatrix} \end{pmatrix}) = \pi(\begin{pmatrix} x \end{pmatrix}) + c \cdot \lambda$ for all $x \in J$ and $\lambda \in \mathbb{R}$ such that $x + \lambda \begin{pmatrix} -1 \\ 1 \end{pmatrix} \in J$. Since $\pi$ is affine on $I$, there exists $c' \in \mathbb{R}$ such that $\pi(v^0 + \lambda \begin{pmatrix} 0 \\ 1 \end{pmatrix}) = \pi(v^0) + c' \cdot \lambda$ for all $0 \leq \lambda \leq \frac{1}{q}$.

Now observe that any point in $J$ can be written as $v^0 + \mu_1(\begin{pmatrix} 0 \\ 1 \end{pmatrix}) + \mu_2(\begin{pmatrix} -1 \\ 1 \end{pmatrix})$ with $0 \leq \mu_1, \mu_2 \leq \frac{1}{q}$ and therefore, $\pi \left(v^0 + \mu_1(\begin{pmatrix} 0 \\ 1 \end{pmatrix}) + \mu_2(\begin{pmatrix} -1 \\ 1 \end{pmatrix})\right) = \pi(v^0 + \mu_1(\begin{pmatrix} 0 \\ 1 \end{pmatrix})) + c \cdot \mu_2$ (using (ii) in the hypothesis) and $\pi \left(v^0 + \mu_1(\begin{pmatrix} 0 \\ 1 \end{pmatrix})\right) + c \cdot \mu_2 = \pi(v^0) + c' \cdot \mu_1 + c \cdot \mu_2$. Thus, $\pi$ is affine over $J$. □
5 Proof of the main results for the two-dimensional case

In this section we prove our main results for continuous piecewise linear functions over $\mathcal{P}_q$.

**Assumption 5.1** For the remainder of the paper, we assume that $\pi$ is a minimal valid function that is continuous piecewise linear over $\mathcal{P}_q$.

**Definition 5.2**
(a) For any $I \in \mathcal{P}_q$, if $\pi$ is affine in $I$ and if for all valid functions $\pi^1, \pi^2$ such that $\pi = \frac{1}{2}(\pi^1 + \pi^2)$ we have that $\pi^1, \pi^2$ are affine in $I$, then we say that $\pi$ is **affine imposing in $I$**.
(b) For any $I \in \mathcal{P}_q$, if $\pi$ is affine with respect to $L_{\infty}$ over $I$ and if for all valid functions $\pi^1, \pi^2$ such that $\pi = \frac{1}{2}(\pi^1 + \pi^2)$ we have that $\pi^1, \pi^2$ are both affine with respect to $L_{\infty}$ over $I$, then we say that $\pi$ is **diagonally affine imposing in $I$**.
(c) For a collection $\mathcal{P} \subseteq \mathcal{P}_q$, if for all $I \in \mathcal{P}$, $\pi$ is affine imposing (or diagonally affine imposing) in $I$, then we say that $\pi$ is **affine imposing (diagonally affine imposing) in $\mathcal{P}$**.

**Section outline**
We either show that $\pi$ is affine imposing in $\mathcal{P}_q$ (Sect. 5.1) or construct a continuous piecewise linear perturbation (Sect. 5.2) that proves $\pi$ is not extreme (Sect. 5.3). If $\pi$ is affine imposing in $\mathcal{P}_q$, we set up a system of linear equations to decide if $\pi$ is extreme or not (Sect. 5.4). This implies Theorem 1.8 stated in the introduction.

5.1 Imposing affine linear properties on faces of $\mathcal{P}_q$

As briefly discussed in Sect. 4.3, the set $E(\pi, \mathcal{P}_q)$ helps one to deduce affine linear properties of $\pi^1, \pi^2$. There are essentially three types of such deductions: (i) Lemma 4.10 and Lemma 4.11 (deducing affine linear properties by Interval Lemma type arguments), (ii) transferring affine linear properties through lower dimensional faces, and (iii) Lemma 4.13, which transfers affine linear properties via adjacency between cells of $\mathcal{P}_q$. We build a finite graph to formally record these interactions in Sect. 5.1.2.

5.1.1 Covered triangles

We now consider faces of $\mathcal{P}_q$ on which we can deduce affine properties.

$$\mathcal{P}^1_{q,\infty} = \{I, J \in \mathcal{P}_q \mid \exists K \in \mathcal{P}_q, F \in E(\pi, \mathcal{P}_q) \text{ with } (I, J, K) = (p_1(F), p_2(F), p_3(F)) \text{ or } (I, K, J) = (p_1(F), p_2(F), p_3(F))\},$$

$$\mathcal{P}^2_{q,\infty} = \{I, J, K \in \mathcal{P}_q \mid \exists F \in E(\pi, \mathcal{P}_q) \text{ with } (I, J, K) = (p_1(F), p_2(F), p_3(F))\}.$$ 

It follows from Lemma 4.10 that $\pi$ is affine imposing in $\mathcal{P}^2_{q,\infty}$ and from Lemma 4.11 that $\pi$ is diagonally affine imposing in $\mathcal{P}^1_{q,\infty}$. The superscripts here correspond to the dimension of the linear space on which $\pi$ is affine imposing on a face.
5.1.2 Finite graph

Next we will define a finite graph $G$ whose nodes correspond to the two-dimensional faces (triangles) in $\mathcal{P}_q$. To make this graph finite, we will use the periodicity of the function $\pi$ and of the complex $\mathcal{P}_q$ modulo $\mathbb{Z}^2$. By $\mathcal{P}_q/\mathbb{Z}^2$ we denote the set of equivalence classes

$$[I] = \{\tau_s(I) = I + s \mid s \in \mathbb{Z}^2\}$$

of two-dimensional faces (triangles) $I \in \mathcal{P}_q$ modulo translations by integer vectors $s \in \mathbb{Z}^2$. We can identify an equivalence class with its unique representative that is a triangle contained in $[0, 1]^2$.

**Definition 5.3** Let $G = G(\mathcal{P}_q, \mathbb{Z}^2, \mathcal{E})$ be the finite undirected graph with node set $\mathcal{P}_q$ and edge set $\mathcal{E}$ where $\{[I], [J]\} \in \mathcal{E}$ (resp., $\{[I], [J]\} \in \mathcal{E}_1$) if and only if $[I] \neq [J]$ and for some $K \in \mathcal{P}_q$ (resp., $K \in \mathcal{P}_q$) and $F \in E(\pi, \mathcal{P}_q)$, we have one of the following cases:

(Case a) $(I, J, K) = (p_1(F), p_2(F), p_3(F))$, which implies $F' := F(J, I, K) \in E(\pi, \mathcal{P}_q)$ with $(J, I, K) = (p_1(F'), p_2(F'), p_3(F'))$, or

(Case b) $(I, K, J) = (p_1(F), p_2(F), p_3(F))$, or

(Case c) $(J, K, I) = (p_1(F), p_2(F), p_3(F))$.

Therefore we record an edge between two cells in $\mathcal{P}_q$ whenever there is an $F \in E(\pi, \mathcal{P}_q)$ such that two of the projections $p_i(F)$, $i = 1, 2, 3$, are these two cells and the third projection is in $\mathcal{P}_q$. By the symmetry between $p_1$ and $p_2$ and the symmetry in the definition of $E(\pi, \mathcal{P}_q)$, for every $F \in E(\pi, \mathcal{P}_q)$ there exists an $F' \in E(\pi, \mathcal{P}_q)$ such that $p_1(F) = p_2(F')$, $p_2(F) = p_1(F')$, and $p_3(F) = p_3(F')$. Therefore, when considering an $F \in E(\pi, \mathcal{P}_q)$ with two projections in $I, J \in \mathcal{P}_q$ and a third projection $K \in \mathcal{P}_q$, we can always assume that either $p_2(F) = K$ or $p_3(F) = K$.

Some faces in $\mathcal{E}_1$ are inherently also in $\mathcal{E}_0$. Figure 7 depicts how this can happen and also shows an edge in $\mathcal{E}_1$ that is not necessarily in $\mathcal{E}_0$. Thus, $\mathcal{E}_0$ alone is not sufficient to describe all the relations in the graph that we need to consider.

The functions $\pi, \pi^1, \pi^2$ have related slopes on faces that are connected in the graph.

**Lemma 5.4** Let $L \subseteq \mathbb{R}^2$ be a linear subspace. Let $I, J \in \mathcal{P}_q$ with $\{[I], [J]\} \in \mathcal{E}$. Suppose $\pi^1, \pi^2$ are valid functions with $\pi = \frac{1}{2}(\pi^1 + \pi^2)$. For $\theta = \pi, \pi^1$, or $\pi^2$, if $\theta$ is affine with respect to $L$ over $I$, then $\theta$ is affine with respect to $L$ over $J$ as well.

**Proof** By Lemma 1.4 and Assumption 1, $\pi^1, \pi^2$ are minimal and continuous and $E(\pi, \mathcal{P}_q) \subseteq E(\theta, \mathcal{P}_q)$ for $\theta = \pi, \pi^1, \pi^2$.

Case (i). Suppose $\{[I], [J]\} \in \mathcal{E}_0$. Then there exists $\mathbf{a} \in \frac{1}{2}\mathbb{Z}^2$ such that, setting $K = \{\mathbf{a}\} \in \mathcal{P}_q$, there exists $F \in E(\pi, \mathcal{P}_q)$ such that either $(I, J, K) = (p_1(F), p_2(F), p_3(F))$, $(I, K, J) = (p_1(F), p_2(F), p_3(F))$, or $(J, K, I) = (p_1(F), p_2(F), p_3(F))$; these are cases a, b, and c from Definition 5.3, respectively. We only consider the case $(I, J, K) = (p_1(F), p_2(F), p_3(F))$; the other cases are...
that is not captured with $\mathcal{E}_{3_{\mathbb{N}}}$.

We show that for any $\pi, \pi', \pi''$, and so we can realize $\mathcal{E}_{3_{\mathbb{N}}}$.

But the third edge, $\mathcal{E}_{3_{\mathbb{N}}}$.

and

Fig. 7 An example of an important edge connection in $\mathcal{E}_{3_{\mathbb{N}}}$ that is not captured with $\mathcal{E}_{3_{\mathbb{N}}}$.

For a given minimal valid function $\pi$, we could have $F(I, J, K_1), F(I, J, K_2), F(I, J, K_3) \in \mathcal{E}_{3_{\mathbb{N}}}$.

Thus, $[J], [K_1], [K_2], [K_3] \in \mathcal{E}_{3_{\mathbb{N}}}$.

Therefore, recording $\mathcal{E}_{3_{\mathbb{N}}}$ is crucial to the construction of $\mathcal{G}(\mathcal{P}_{q, \mathbb{N}})$.

similar. Then $\theta|_J(x) + \theta|_J(y) = \theta|_K(a)$ for all $x \in I, y \in J, x + y = a$.

Consider any $y^1, y^2 \in J$ such that $y^2 - y^1 \in L$. Set $x^i = a - y^i \in I$ for $i = 1, 2$.

Thus, $\theta|_J(y^2) - \theta|_J(y^1) = \theta|_J(x^1) - \theta|_J(x^2)$ and $x^1 - x^2 = y^2 - y^1 \in L$.

Since $\theta$ is affine with respect to $L$ over $I$, $\theta$ is affine with respect to $L$ over $J$.

Case (ii). Suppose $[I], [J] \in \mathcal{E}_{3_{\mathbb{N}}}$.

We show that for any $y \in \text{rel int}(J)$, and any $p \in L$ there exists $\epsilon > 0$ such that $\theta$ is affine over $\{y + \lambda p \mid -\epsilon \leq \lambda \leq \epsilon\}$.

Using Lemma 2.7, this will then imply that $\theta$ is affine with respect to $L$ over $J$.

Let $y \in \text{rel int}(J)$.

Using Lemma 2.9, there exists $x \in \text{rel int}(I)$ and $a \in \text{rel int}(K)$ such that $x + y = a$.

Since $y \in \text{rel int}(J)$, there exists $\epsilon > 0$ such that $x + \lambda p \mid -\epsilon \leq \lambda \leq \epsilon \subseteq I$ and $\{y + \lambda p \mid -\epsilon \leq \lambda \leq \epsilon\} \subseteq J$.

Since $\theta$ is affine over $\{x + \lambda p \mid -\epsilon \leq \lambda \leq \epsilon\} \subseteq I$ and $\theta|_J(x) + \theta|_J(y) = \theta|_K(a)$ for all $x \in I, y \in J, x + y = a$.

A similar argument as case (i) proves $\theta$ is affine over $\{y + \lambda p \mid -\epsilon \leq \lambda \leq \epsilon\}$.

With this in mind, for each $I \in \mathcal{P}_{q, \mathbb{N}}$, let $\mathcal{G}_I$ be the connected component of $\mathcal{G}$ containing $[I]$.

We define the two sets of faces that contain complete connected components in the graph $\mathcal{G}$,

$$
\mathcal{S}^1_{q, \mathbb{N}} = \{J \in \mathcal{P}_{q, \mathbb{N}} \mid [J] \in \mathcal{G}_I \text{ for some } I \in \mathcal{P}^1_{q, \mathbb{N}}\}.
$$

$$
\mathcal{S}^2_{q, \mathbb{N}} = \{J \in \mathcal{P}_{q, \mathbb{N}} \mid [J] \in \mathcal{G}_I \text{ for some } I \in \mathcal{P}^2_{q, \mathbb{N}}\}.
$$

Observation 5.5 It follows from Lemma 5.4, Lemma 4.10 and the periodicity of $\pi$, $\pi'$, and $\pi''$ that $\pi$ is affine imposing in $\mathcal{S}^2_{q, \mathbb{N}}$.

Similarly, it follows from Lemma 5.4, Lemma 4.11 and the periodicity of $\pi$, $\pi'$, and $\pi''$ that $\pi$ is diagonally affine imposing in $\mathcal{S}^1_{q, \mathbb{N}}$.

Springer
Observation 5.6 (Geometrically adjacent triangles) From Lemma 4.13, it follows that if \( I \in S^2_q \triangleq \mathcal{P}_q / \mathbb{Z}^2 \) and \( I \cap J \in \mathcal{P}_q \), then \( \pi \) is affine imposing in \( J \). Furthermore, by periodicity of \( \pi \), \( \pi^1 \), and \( \pi^2 \) is affine imposing in all \( J' \in [J] \).

This observation motivates the following graph definition that is a super-graph of \( \mathcal{G} \).

Definition 5.7 Let \( \tilde{\mathcal{G}} = \tilde{\mathcal{G}}(\mathcal{P}_q / \mathbb{Z}^2, \tilde{\mathcal{E}}) \) be the finite undirected graph with node set \( \mathcal{P}_q / \mathbb{Z}^2 \) and edge set \( \tilde{\mathcal{E}} = \mathcal{E}_q \cup \mathcal{E}_q \cup \mathcal{E}_q \) where \( \mathcal{E}_q \) and \( \mathcal{E}_q \) are defined in Definition 5.3 and where \( [[I], [J]] \in \mathcal{E}_q \) if and only if \( [I] \neq [J] \) and for some \( I' \in [I], J' \in [J] \) we have \( I', J' \in S^1_q \) and \( I \cap J \in \mathcal{P}_q \).

In contrast to the graph \( \mathcal{G} \) and Lemma 5.4, faces in \( \tilde{\mathcal{G}} \) connected by edges from \( \mathcal{E}_q \) do not necessarily have related slopes, even if \( \pi \) is affine imposing on these faces.

For each \( I \in \mathcal{P}_q \), let \( \tilde{\mathcal{G}}_I \) be the connected component of \( \tilde{\mathcal{G}} \) containing \( [I] \). Let

\[
\tilde{S}^2_q = \{ K \in \mathcal{P}_q : [K] \in \tilde{\mathcal{G}}_I \text{ for some } I \in S^2_q \}.
\]

Note that \( \tilde{S}^2_q \subseteq S^1_q \). Let

\[
\tilde{S}^1_q = S^1_q \setminus \tilde{S}^2_q.
\]

Theorem 5.8 If \( \tilde{S}^2_q = \mathcal{P}_q \) then \( \pi \) is affine imposing in \( \mathcal{P}_q \), and therefore \( \theta \) is continuous piecewise linear over \( \mathcal{P}_q \) for \( \theta = \pi^1 + \pi^2 \) whenever we have that \( \pi^1, \pi^2 \) are valid functions and \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \).

Proof By Lemma 1.4, \( \pi^1, \pi^2 \) are minimal and continuous. Since they are minimal, they are also periodic. From Observation 5.5, \( \pi \) is affine imposing in \( S^2_q \) and diagonally affine imposing in \( S^1_q \). By Observation 5.6, \( \pi \) is affine imposing in any \( J' \) such that there exists a \( J \in [J'] \) and \( I \cap J \in \mathcal{P}_q \) for some \( I \) such that \( \pi \) is affine imposing in \( I \). In particular, this holds for all \( I \in S^2_q \). Consider any \( K \in S^1_q \) where \( [K] \) is connected by a path to \([I] \) in the graph \( \mathcal{G} \). By induction on the number of edges in the path from \([K] \) to \([I] \) and using Lemma 5.4, \( \pi \) is affine imposing in \( K \). Therefore, \( \pi \) is affine imposing in \( S^1_q \cap \tilde{S}^2_q \). Since \( \mathcal{P}_q = \tilde{S}^2_q \subseteq S^1_q \cup \tilde{S}^2_q \subseteq \mathcal{P}_q \), it follows that \( \pi \) is affine imposing in all of \( \mathcal{P}_q \). \( \square \)

5.2 Perturbation functions

In this section we study functions \( \psi : \mathbb{R}^2 \to \mathbb{R} \) that satisfy entire classes of additivity relations that appear in \( E(\pi, \mathcal{P}_q) \). These will be used to construct perturbation functions \( \tilde{\pi} \) such that \( E(\pi) \subseteq E(\tilde{\pi}) \). We may then leverage Theorem 3.13 to show that \( \pi \) is not extreme.
For $m \geq 3$, we will use the subtriangulation (refinement) $P_{mq}$ of $P_q$. We define $\psi_{mq}^m : \mathbb{R}^2 \to \mathbb{R}$ that is piecewise linear over $P_{mq}$ as follows: at all vertices of $P_{mq}$ that lie on the boundary of $0$, let $\psi_{mq}^m$ take the value 0, and at all vertices of $P_{mq}$ that lie in the interior of $0$, we assign $\psi_{mq}^m$ to have the value 1. Interpolate these values linearly to define $\psi_{mq}^m$ on all of $0$. For every point $x$ in $0$, define $\psi_{mq}^m(x) = -\psi_{mq}^m(1/q - x)$. Finally, for any $y \in \mathbb{R}^2$, let $x \in [0, 1/q]$ and $t \in 1/q \mathbb{Z}^2$ be vectors such that $y = x + t$; define $\psi_{mq}^m(y) = \psi_{mq}^m(x)$. Since $\psi_{mq}^m$ vanishes on the boundary of $[0, 1/q]^2$, this periodic extension is well-defined. The function for $m = 3$ is shown in Fig. 8 (left).

The following result is quite easy to verify from the definition of $\psi_{mq}^m$. Formally, the assertions follow from (i), (iv) and (v) in Lemma A.7, in “Appendix 1”, whose proof uses more general tools which, in our opinion, are of independent interest.

**Lemma 5.9** For every $m \geq 3$, the function $\psi_{mq}^m : \mathbb{R}^2 \to \mathbb{R}$ constructed above has the following properties:

(i) $\psi_{mq}^m|_I = 0$ on all edges and vertices $I \in \Delta P_{mq}$.

(ii) Let $i = 1, 2$ or 3, and let $F \in \Delta P_q$ be such that $p_i(F) \in P_{mq}$. Then, $F \subseteq E(\psi_{mq}^m)$.

(iii) $\psi_{mq}^m$ is continuous piecewise linear over $P_{mq}$.

We will also need another class of functions $\psi_{mq}^m : \mathbb{R}^2 \to \mathbb{R}$ parametrized by $m \geq 3$. Let $\psi_{mq}^m : \mathbb{R}^2 \to \mathbb{R}$ be the piecewise linear function over $P_{mq}$ defined in the following way. The values on the vertices of $P_{mq}$ are given as follows: for any

![Fig. 8 Perturbation functions $\psi_{mq}^m$ (left) and $\psi_{mq}^m$ (right) for $m = 3$. Colors indicate whether the value of the function is negative (red), positive (green), zero (white). Two polyhedral complexes are drawn: $P_q$ (thick lines) and its refinement $P_{mq}$ (thin lines) (color figure line)](image.png)
\( x \in \text{vert}(P_{mq}), \)

\[
\psi^{m}_{q, \mathbb{N}}(x) = \begin{cases} 
1 & \text{if } 1 \cdot x \equiv \frac{i}{mq} \pmod{\frac{1}{q}} \text{ for any } 1 \leq i < \frac{m}{2}, \ i \in \mathbb{Z}, \\
-1 & \text{if } 1 \cdot x \equiv \frac{i}{mq} \pmod{\frac{1}{q}} \text{ for any } \frac{m}{2} < i \leq m - 1, \ i \in \mathbb{Z}, \\
0 & \text{if } 1 \cdot x \equiv 0 \text{ or } \frac{1}{2q} \pmod{\frac{1}{q}}.
\end{cases}
\]

The function \( \psi^{m}_{q, \mathbb{N}} \) is then uniquely extended to \( \mathbb{R}^2 \) continuously by interpolation on the faces of \( P_{mq} \). The function is shown for \( m = 3 \) in Fig. 8 (right).

The next result can also be easily verified from the definition of the function \( \psi^{m}_{q, \mathbb{N}} \).

Formally, we again the assertions follow from (i), (iv) and (v) in Lemma A.8 in “Appendix 1”.

**Lemma 5.10** The function \( \psi^{m}_{q, \mathbb{N}} : \mathbb{R}^2 \rightarrow \mathbb{R} \) constructed above is well-defined and has the following properties:

1. \( \psi^{m}_{q, \mathbb{N}} \) is continuous piecewise linear over \( P_{mq} \).
2. Let \( i = 1, 2, \) or \( 3 \) and let \( F \in \Delta P_q \) be such that \( p_i(F) \in P_{mq} \). Then, \( F \subseteq E(\psi^{m}_{q, \mathbb{N}}) \).
3. \( \psi^{m}_{q, \mathbb{N}} \) is continuous piecewise linear over \( P_{mq} \).

### 5.3 Non-extremality by equivariant perturbation

In this subsection, we will prove the following lemma that shows that when \( \pi \) is piecewise linear over \( P_q \), it must be affine imposing for it to be extreme. This is done by defining specific perturbations that can be used to show \( \pi \) is not extreme.

We will derive sufficient conditions for extremality in the subsequent subsection.

**Lemma 5.11** Let \( \pi \) be a minimal, continuous piecewise linear function over \( P_q \) with \( f \in \text{vert}(P_q) \) that is diagonally constrained. Suppose there exists \( I^* \in P_q \) \( \backslash \) \( (S^2_{q, \mathbb{N}} \cup S^1_{q, \mathbb{N}}) \). Then \( \pi \) is not extreme.

In the proof, we will need \( \psi^{m}_{q, \mathbb{N}} \) and \( \psi^{m}_{q, \mathbb{N}} \) as constructed in Sect. 5.2. We first will analyze a case that uses \( \psi^{m}_{q, \mathbb{N}} \).

Recall that \( \Delta \pi(x, y) := \pi(x) + \pi(y) - \pi(x + y) \) and that when \( \pi \) is piecewise linear over \( P_q \), we have that \( \Delta \pi \) is piecewise linear over \( \Delta P_q \), as explained in Sect. 4.

**Lemma 5.12** (Perturbation only on interior of triangles) Let \( \pi \) be a minimal, continuous piecewise linear function over \( P_q \) with \( f \in \text{vert}(P_q) \) that is diagonally constrained. Suppose there exists \( I^* \in P_q \) \( \backslash \) \( (S^2_{q, \mathbb{N}} \cup S^1_{q, \mathbb{N}}) \). Then \( \pi \) is not extreme.

Furthermore, for any \( m \in \mathbb{Z}_{\geq 3} \), there exist distinct minimal valid functions \( \pi^1, \pi^2 \) that are continuous piecewise linear over \( P_{mq} \) such that \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \).

**Proof** Fix \( m \in \mathbb{Z}_{\geq 3} \). Let \( R = \bigcup \{ J \mid [J] \in G_{I^*} \} \). Let \( \psi^{m}_{q, \mathbb{N}} : \mathbb{R}^2 \rightarrow \mathbb{R} \) be the function constructed in Sect. 5.2. Let \( \tilde{\pi} = \delta_R \cdot \psi^{m}_{q, \mathbb{N}} \) where \( \delta_R \) is the indicator function for the set \( R \). Since \( \{0\}, \{f\} \in P_{q, \mathbb{N}} \), by Lemma 5.9(i), we have \( \psi^{m}_{q, \mathbb{N}}(0) = 0 \) and \( \psi^{m}_{q, \mathbb{N}}(f) = 0 \). Hence, \( \tilde{\pi}(0) = 0 \) and \( \tilde{\pi}(f) = 0 \).
Since \( \psi_{q,1}^m |_I = 0 \) for all \( I \in \mathcal{P}_{q,1,2,2} \) and \( R \) is a union of faces in \( \mathcal{P}_{q,1,2,2} \), we find that \( \bar{\pi} \) is continuous. Since \( \psi_{q,1}^m \) is piecewise linear over \( \mathcal{P}_{mq} \), \( \bar{\pi} \) is also piecewise linear over \( \mathcal{P}_{mq} \). Finally, notice that \( \bar{\pi} \) is periodic modulo \( \mathbb{Z}^2 \) since \( \psi_{q,1}^m \) and \( \delta_R \) are both periodic modulo \( \mathbb{Z}^2 \).

We will show that \( E(\pi) \subseteq E(\bar{\pi}) \). Since \( I^* \in R \) and \( \psi_{q,1}^m \not\equiv 0 \) on \( \text{int}(I^*) \), we have that \( \bar{\pi} \neq 0 \). Since \( \bar{\pi}(f) = 0 \) and \( \bar{\pi} \neq 0 \), by Theorem 3.13, this will show that \( \pi \) is not extreme. By Lemma 3.12, we only need to consider maximal faces in the complex \( \Delta \mathcal{P}_q \). Let \( F \in E_{\text{max}}(\pi, \mathcal{P}_q) \). Define \( \Delta \bar{\pi}(x, y) := \bar{\pi}(x) + \bar{\pi}(y) - \bar{\pi}(x + y) \).

We will show that \( \Delta \bar{\pi}|_F = 0 \). Note that \( \bar{\pi} \) is defined over the finer complex \( \mathcal{P}_{mq} \). Therefore \( \Delta \bar{\pi} \) is piecewise linear over \( \Delta \mathcal{P}_{mq} \). Since \( F \in \Delta \mathcal{P}_q \), the function \( \Delta \bar{\pi} \) is not necessarily affine over \( F \).

Let \( I = p_1(F), J = p_2(F) \), and \( K = p_3(F) \). By Lemma 3.5, \( F = F(I, J, K) \).

Since \( \pi \) is diagonally constrained, we enumerate the possible cases for \( I, J, K \) as listed in Lemma 4.9 and show that \( F = F(I, J, K) \subseteq E(\bar{\pi}) \). Observe that we can write \( \Delta \bar{\pi}|_F(x, y) = \bar{\pi}|_F(x) + \bar{\pi}|_F(y) - \bar{\pi}|_K(x + y) \) and that \( F \subseteq E(\bar{\pi}) \) if and only if \( \Delta \bar{\pi}|_F = 0 \).

(Type 1) \( I, J, K \in \mathcal{P}_{q,1,2,2} \). By Lemma 5.9 (i), \( \psi_{q,1}^m = 0 = \bar{\pi} \) on the faces \( I, J, K \) and thus we have \( \Delta \bar{\pi}|_F = 0 \).

(Type 2) \( I, J, K \in \mathcal{P}_{q,1,2,2} \). By definition of \( S^2_{q,1,2,2} \), we have \( I, J, K \in S^2_{q,1,2,2} \).

Therefore \( I \cap R, J \cap R, K \cap R \in \mathcal{P}_{q,1,2,2} \). By Lemma 5.9 (i), \( \psi_{q,1}^m = 0 \) on \( I \cap R, J \cap R, K \cap R \). Since \( \delta_R = 0 \) on \( I \cap R, J \cap R, K \cap R \), we have \( \bar{\pi} = 0 \) on \( I, J, K \) and thus \( \Delta \bar{\pi}|_F = 0 \).

(Type 3) One of \( I, J, K \) is in \( \mathcal{P}_{q,1,2,2} \), while the other two are in \( \mathcal{P}_{q,1,2,2} \). Label \( I, J, K \) as \( I', J', K' \) where \( I' \in \mathcal{P}_{q,1,2,2} \) and \( J', K' \in \mathcal{P}_{q,1,2,2} \). By Lemma 5.9 (i), \( \psi_{q,1}^m = 0 = \bar{\pi} \) on \( I' \). We consider four cases.

Case i. \( [J'], [K'] \not\in \mathcal{G}_{I^*} \). Then \( J' \cap R, K' \cap R \in \mathcal{P}_{q,1,2,2} \). By Lemma 5.9 (i), \( \psi_{q,1}^m = 0 = \bar{\pi} \) on \( J' \cap R \) and \( K' \cap R \). Furthermore, \( \delta_R = 0 \) on \( J' \cap R \) and \( K' \cap R \). Hence, \( \bar{\pi} = 0 \) on \( I', J', K' \) and hence \( \Delta \pi|_F = 0 \).

Case ii. \( [J'], [K'] \in \mathcal{G}_{I^*} \). By the relations in Lemma 5.9 (ii) and the fact that \( \delta_R = 1 \) on \( J', K' \), we have that \( \Delta \bar{\pi}|_F = 0 \).

Case iii. \( [J'] \in \mathcal{G}_{I^*}, [K'] \not\in \mathcal{G}_{I^*} \). We show that this case cannot happen. Since \( F \in E(\pi) \) and \( I' \in \mathcal{P}_{q,1,2,2} \), we have that \( [[J'], [K']] \in S_{q,1,2,2}^2 \). Therefore, \( [K'] \not\in \mathcal{G}_{J^*} \). Since \( [J'] \in \mathcal{G}_{I^*} \), we have that \( \mathcal{G}_{I^*} = \mathcal{G}_{J^*} \), which is a contradiction because then \( [K'] \in \mathcal{G}_{J^*} \).

Case iv. \( [K'] \in \mathcal{G}_{I^*}, [J'] \not\in \mathcal{G}_{I^*} \). This is similar to the previous case.

(Type 4) One of \( I, J, K \) is in \( \mathcal{P}_{q,1,2,2} \), while the other two are in \( \mathcal{P}_{q,1,2,2} \). In this case, by definition, the two triangles are in \( S^1_{q,1,2,2} \). Since triangles in \( S^1_{q,1,2,2} \) only intersect \( R \) on lower-dimensional faces \( \mathcal{P}_{q,1,2,2} \), we have that \( I \cap R, J \cap R, K \cap R \in \mathcal{P}_{q,1,2,2} \). By Lemma 5.9 (i), \( \psi_{q,1}^m = 0 = \bar{\pi} \) on \( I \cap R, J \cap R, K \cap R \). Since \( \delta_R = 0 \) on \( I \cap R, J \cap R, K \cap R \), we have \( \bar{\pi} = 0 \) on \( I, J, K \) and we have \( \Delta \bar{\pi}|_F = 0 \).
Fig. 9 A case where $P_q,_{0} = S^2_q,_{0} \cup S^1_q,_{0} = S^2_q,_{0} \cup S^1_q,_{0}$. Therefore, on every triangle, $\pi$ is either affine imposing (shaded triangles), or only diagonally affine imposing (striped triangles). Observation 5.6 shows that a shaded triangle that is geometrically adjacent to a striped triangle along a vertical or horizontal face in $P_q,_{0}$ forces the striped triangle to become shaded. Therefore, no striped triangle can be geometrically adjacent to a shaded triangle along a vertical or horizontal face in $P_q,_{0}$.

In this example, every striped triangle is connected in the graph $\bar{G}$ by a path with edges in $E$. Therefore, all of these triangles form a connected component in the graph. We can choose any one of these triangles as $I^*$ in Lemma 5.14 to perturb on this connected component.

We conclude that $E(\pi) \subseteq E(\bar{\pi}), \bar{\pi}(f) = 0$, and $\pi$ and $\bar{\pi}$ are both piecewise linear over $P_{mq}$. Therefore, by Theorem 3.13, $\pi$ is not extreme and there exist distinct minimal functions $\pi^1, \pi^2$ that are continuously piecewise linear over $P_{mq}$. \hfill $\Box$

We next use the function $\psi^m_{q,\square}$ as defined in Sect. 5.2, as the basis for a perturbation function $\bar{\pi}$.

As in Lemma 5.12, we will allow the perturbation $\bar{\pi}$ to only apply to a subset of the triangles, this time corresponding to a connected component in the graph $\tilde{G}$. Since $\psi^m_{q,\square}$ is non-zero on the vertical and horizontal faces $P_q,_{0}$, we must be careful about geometrically adjacent triangles.

To handle the geometrically adjacent triangles easier, we consider the case where $P_q,_{0} = S^2_q,_{0} \cup S^1_q,_{0}$.

Observation 5.13 Suppose $P_q,_{0} = S^2_q,_{0} \cup S^1_q,_{0}$ and let $I^* \in \bar{S}^1_q,_{0}$. Let $J, K \in P_q,_{0}$ such that $[J] \in \tilde{G}_{I^*}$ and $J \cap K \in P_q,_{0}$. Then $[K] \in \tilde{G}_{I^*}$ as well. This is because $P_q,_{0} = S^2_q,_{0} \cup S^1_q,_{0}$ and therefore $\{[J], [K]\} \in \tilde{E} \subseteq \tilde{E}$; see Fig. 9.

Lemma 5.14 (Diagonal perturbation touching vertical and horizontal boundaries of triangles) Suppose $\pi$ is continuous piecewise linear over $P_q$ with $f \in \text{vert}(P_q)$ and is diagonally constrained. Suppose further that $P_q,_{0} = S^2_q,_{0} \cup S^1_q,_{0}$ and there exists $I^* \in \bar{S}^1_q,_{0}$. Then $\pi$ is not extreme.

Furthermore, for any $m \in \mathbb{Z}_{\geq 3}$, there exist distinct minimal valid functions $\pi^1, \pi^2$ that are continuous piecewise linear over $P_{mq}$ such that $\pi = \frac{1}{2}(\pi^1 + \pi^2)$. \hfill $\square$ Springer
Proof Let $R = \bigcup \{J \in P_{q\overline{q}} \mid [J] \in \tilde{G}_J^{\ast}\}$. Note that $\tilde{G}_J^{\ast} \subseteq \tilde{S}^1_{q\overline{q}}$ and recall that $\tilde{S}^1_{q\overline{q}} \cap \tilde{S}^2_{q\overline{q}} = \emptyset$. Furthermore, $\tilde{S}^1_{q\overline{q}} \cap S^2_{q\overline{q}} = \emptyset$. Let $\psi_{m_{q\overline{q}}} : \mathbb{R}^2 \to \mathbb{R}$ be the function constructed in Sect. 5.2.

Let $\tilde{\pi} = \delta_R(x) \cdot \psi_{m_{q\overline{q}}}(x)$. First recognize that $\tilde{\pi}$ is a continuous function. To see this, note that $\psi_{m_{q\overline{q}}}(x)$ is continuous and $\delta_R$ is continuous on $R$ and $\mathbb{R}^2 \setminus R$. By Observation 5.13, it follows that $\partial R \subseteq \bigcup \{I \mid I \in P_{q\overline{q}}\}$. By Lemma 5.10 (i), $\psi_{m_{q\overline{q}}}$ vanishes on $\partial R$, that is $\psi_{m_{q\overline{q}}} = 0$ on $\partial R$. These together imply that $\tilde{\pi}$ is continuous.

Since $\psi_{m_{q\overline{q}}}$ is piecewise linear over $P_{mq}$, $\tilde{\pi}$ is also piecewise linear over $P_{mq}$. Also, since $\psi_{m_{q\overline{q}}} \mid I = 0$ for all $I \in P_{q\overline{q}}$, we find $\tilde{\pi}$ is also continuous. Finally, notice that $\tilde{\pi}$ is periodic modulo $\mathbb{Z}^2$ since $\psi_{m_{q\overline{q}}}$ and $\delta_R$ are both periodic modulo $\mathbb{Z}^2$.

We will show that $E(\pi) \subseteq E(\tilde{\pi})$. Since $I^* \in R$ and $\psi_{m_{q\overline{q}}} \neq 0$ on int$(I^*)$, we have $\tilde{\pi} \neq 0$. Since $\tilde{\pi}(f) = 0$ and $\tilde{\pi} \neq 0$, by Theorem 3.13, this will show that $\pi$ is not extreme. By Lemma 3.12, we only need to consider maximal faces in the complex $\Delta_{P_{q\overline{q}}}$. Let $F \in E_{\max}(\pi, P_{q\overline{q}})$.

Define $\Delta{\tilde{\pi}}(x, y) := \tilde{\pi}(x) + \tilde{\pi}(y) - \tilde{\pi}(x + y)$. We will show that $\Delta{\tilde{\pi}} \mid F = 0$. Note that $\tilde{\pi}$ is defined over the finer complex $P_{mq}$. Therefore $\Delta{\tilde{\pi}}$ is piecewise linear over $\Delta_{P_{mq}}$. Since $F \in \Delta_{P_{q\overline{q}}}$, the function $\Delta{\tilde{\pi}}$ is not necessarily affine over $F$.

Let $I = p_1(F)$, $J = p_2(F)$, and $K = p_3(F)$. By Lemma 3.5, $F = F(I, J, K)$. Since $\pi$ is diagonally constrained, we enumerate the possible cases for $I, J, K$ as listed in Lemma 4.9 and show that $F = F(I, J, K) \subseteq E(\tilde{\pi})$. Observe that we can write $\Delta{\tilde{\pi}} \mid F(x, y) = \tilde{\pi} \mid J(x) + \tilde{\pi} \mid J(y) - \tilde{\pi} \mid K(x + y)$ and that $F \subseteq E(\tilde{\pi})$ if and only if $\Delta{\tilde{\pi}} \mid F = 0$.

(Type 1) $I, J, K \in P_{q\overline{q}}$. By Lemma 5.10 (i), $\psi_{m_{q\overline{q}}} = 0 = \tilde{\pi}$ on all faces $I, J, K$ and thus we have $\Delta{\tilde{\pi}} \mid F = 0$.

(Type 2) $I, J, K \in P_{q\overline{q}}$. By definition of $\tilde{S}^2_{q\overline{q}}$, we have $I, J, K \in \tilde{S}^2_{q\overline{q}}$. By Observation 5.13, we must have $I \cap R, J \cap R, K \cap R \in P_{q\overline{q}}$ and hence $\psi_{m_{q\overline{q}}} = 0$ on $I \cap R, J \cap R, K \cap R$ by Lemma 5.10 (i). Therefore, $\tilde{\pi} = 0$ on $I, J, K$ and we have $\Delta{\tilde{\pi}} \mid F = 0$.

(Types 3 and 4) One of $I, J, K$ is in $P_{q\overline{q}}$, while the other two are in $P_{q\overline{q}}$. Label $I, J, K$ as $I', J', K'$ where $I' \in P_{q\overline{q}}$ and $J', K' \in P_{q\overline{q}}$. By Lemma 5.10 (i), $\psi_{m_{q\overline{q}}} = 0$ on $I'$. We consider four cases.

Case i. $[J'], [K'] \notin \tilde{G}_J^{\ast}$. By Observation 5.13, we must have $J' \cap R, K' \cap R \in P_{q\overline{q}}$. Therefore, by Lemma 5.10 (i), $\psi_{m_{q\overline{q}}} = 0$ on $J' \cap R, K' \cap R$, while $\delta_R = 0$ on $J' \setminus R$, and $K' \setminus R$. Therefore $\tilde{\pi} = 0$ on $I, J, K$ and hence $\Delta{\tilde{\pi}} \mid F = 0$.

Case ii. $[J'], [K'] \in \tilde{G}_J^{\ast}$. By Lemma 5.10 (ii) and the fact that $\delta_R = 1$ on $J', K'$, we have that $\Delta{\tilde{\pi}} \mid F = 0$.

Case iii. $[J'] \notin \tilde{G}_J^{\ast}, [K'] \notin \tilde{G}_J^{\ast}$. We show that this case cannot happen. Since $F \subseteq E(\pi)$ and $I' \in P_{q\overline{q}}$, we have that $([J'], [K']) \in E \subseteq \bar{E}$. Therefore, $[K'] \in \tilde{G}_J$. Since $[J'] \in \tilde{G}_J^{\ast}$, we have that $\tilde{G}_J^{\ast} = \tilde{G}_J$, which is a contradiction because then $[K'] \notin \tilde{G}_J^{\ast}$.

Case iv. $[K'] \in \tilde{G}_J^{\ast}, [J'] \notin \tilde{G}_J^{\ast}$. This is similar to the previous case.
We conclude that $E(\pi) \subseteq E(\bar{\pi})$, $\bar{\pi}(f) = 0$, and $\pi$ and $\bar{\pi}$ are both continuous piecewise linear over $P_{mq}$. Therefore, by Theorem 3.13, $\pi$ is not extreme and there exist distinct minimal functions $\pi^1, \pi^2$ that are continuously piecewise linear over $P_{mq}$. \hfill \qed

**Proof of Lemma 5.11** This follows directly from Lemmas 5.12 and 5.14. \hfill \qed

The specific form of our perturbations as continuous piecewise linear functions over $P_{mq}$ implies the following corollary.

**Corollary 5.15** Fix $m \in \mathbb{Z}_{\geq 3}$. Suppose $\pi$ is a continuous piecewise linear function over $P_q$ and is diagonally constrained. If $\pi$ is not affine imposing over $P_q$, then there exist distinct minimal $\pi^1, \pi^2$ that are continuous piecewise linear over $P_{mq}$ such that $\pi = \frac{1}{2}(\pi^1 + \pi^2)$.

### 5.4 Extremality and non-extremality by linear algebra

In this section we suppose $\pi$ is a minimal continuous piecewise linear function over $P_q$ that is affine imposing in $P_q$. Therefore, by Lemma 1.4 and Definition 5.2, $\pi^1$ and $\pi^2$ must also be minimal continuous piecewise linear functions over $P_q$. Recall from Lemma 1.4 that $E(\pi) \subseteq E(\pi^1), E(\pi^2)$.

We now set up a system of linear equations that $\pi$ satisfies and that $\pi_1$ and $\pi_2$ must also satisfy. Let $\varphi : \frac{1}{q}\mathbb{Z}^2 \to \mathbb{R}$ be a periodic function modulo $\mathbb{Z}^2$. Suppose $\varphi$ satisfies the following system of linear equations:

$$
\begin{align*}
\varphi(0) &= 0, \\
\varphi(f) &= 1, \\
\varphi(u) + \varphi(v) &= \varphi(u + v) \quad \text{for all } u, v \in \frac{1}{q}\mathbb{Z}^2 \text{ with } \pi(u) + \pi(v) = \pi(u + v). \\
\end{align*}
$$

(E_q(\pi))

Since $\pi$ exists and satisfies (E_q(\pi)), we know that the system has a solution. Since $\varphi$ and $\pi$ are periodic, we can identify variables $\varphi(x)$ and $\varphi(x + t)$ for $x \in \frac{1}{q}\mathbb{Z}^2$ and $t \in \mathbb{Z}^2$, and thus the system can be represented with finitely many variables and finitely many equations.

**Theorem 5.16** Let $\pi : \mathbb{R}^2 \to \mathbb{R}$ be a continuous piecewise linear valid function over $P_q$.

(i) If the system (E_q(\pi)) does not have a unique solution, then $\pi$ is not extreme.
(ii) Suppose $\pi$ is minimal and affine imposing in $P_q$. Then $\pi$ is extreme if and only if the system of equations (E_q(\pi)) has a unique solution.

The proof is similar to the proof of [5, Theorem 4.11].

**Proof** Part (i). Suppose (E_q(\pi)) does not have a unique solution. Let $\tilde{\varphi} : \frac{1}{q}\mathbb{Z}^2 \to \mathbb{R}$ be a non-trivial element in the kernel of the system above. Then for any $\epsilon, \pi : \frac{1}{q}\mathbb{Z}^2 + \epsilon\tilde{\varphi}$ also satisfies the system of equations. Let $\tilde{\pi} : \mathbb{R}^2 \to \mathbb{R}$ be the continuous piecewise linear extension of $\tilde{\varphi}$ over $P_q$. Therefore $\tilde{\pi}(f) = 0$ and $\tilde{\pi} \neq 0$. Let $u, v \in \frac{1}{q}\mathbb{Z}^2$. \hfill \qed
If $\Delta \pi(u, v) = 0$, then $\Delta \varphi(u, v) = 0$, as implied by the system of equations. Since $\text{vert}(\Delta P_q) \subseteq \frac{1}{q}\mathbb{Z}^2$, this shows that for any $x, y \in \mathbb{R}^2$, $\Delta \pi(x, y) = 0$ implies that $\Delta \pi(x, y) = 0$. Therefore $E(\pi) \subseteq E(\pi)$. Therefore, by Theorem 3.13, $\pi$ is not extreme.

**Part (ii).** Suppose there exist distinct, valid functions $\pi_1, \pi_2$ such that $\pi = \frac{1}{2}(\pi_1 + \pi_2)$. Since $\pi$ is minimal and affine imposing in $P_q$, $\pi_1, \pi_2$ are minimal continuous piecewise linear functions over $P_q$. Furthermore, $\pi |_{\frac{1}{q}\mathbb{Z}^2}$ and, also $\pi_1 |_{\frac{1}{q}\mathbb{Z}^2}, \pi_2 |_{\frac{1}{q}\mathbb{Z}^2}$ satisfy the system of equations $(E_{pq}(\pi))$. If this system has a unique solution, then $\pi = \pi_1 = \pi_2$, which is a contradiction since $\pi_1, \pi_2$ were assumed distinct. Therefore $\pi$ is extreme.

On the other hand, if the system $(E_{pq}(\pi))$ does not have a unique solution, then by Part (i), $\pi$ is not extreme.  

5.5 Connection to a finite group problem

**Theorem 5.17**  Fix $m \in \mathbb{Z}_{\geq 3}$. Let $\pi$ be a minimal continuous piecewise linear function over $P_q$ that is diagonally constrained. Then $\pi$ is extreme if and only if the system of equations $(E_{mq}(\pi))$ with $\frac{1}{mq}\mathbb{Z}^2$ has a unique solution.

**Proof** Since $\pi$ is piecewise linear over $P_q$, it is also piecewise linear over $P_{mq}$. The forward direction is the contrapositive of Theorem 5.16 (i), applied when we view $\pi$ as piecewise linear over $P_{mq}$. For the reverse direction, observe that if the system of equations $(E_{mq}(\pi))$ has a unique solution, then there cannot exist distinct minimal $\pi_1, \pi_2$ that are continuous piecewise linear over $P_{mq}$ such that $\pi = \frac{1}{2}(\pi_1 + \pi_2)$. By the contrapositive of Corollary 5.15, $\pi$ is affine imposing in $P_q$. Then $\pi$ is also affine imposing on $P_{mq}$ since it is a finer set. By Theorem 5.16 (ii), since $\pi$ is affine imposing in $P_{mq}$, the system of equations $(E_{mq}(\pi))$ on $P_{mq}$ has a unique solution, $\pi$ is extreme.  

Theorems 1.8 and 1.9 are direct consequences of Theorem 5.17.

6 Conclusions

In the present paper, we have focused on the diagonally constrained case. In a similar way, *horizontally constrained* or *vertically constrained* minimal functions can be defined, and the theory developed in this paper can be easily adapted to these cases.

The general case in which the restriction to diagonally constrained functions is removed and thus all degenerations of maximal additive faces are allowed (see Fig. 6, top) requires the solutions of more general functional equations and leads to the construction of more complicated perturbation functions. This is analogous to the history of the one-dimensional ($k = 1$) functions. Prior to the work in [5], extremality proofs were known only for full-dimensionally constrained piecewise linear functions (see Fig. 6, left). A new idea was needed to handle the more general case for $k = 1$. Similar development for $k = 2$ is deferred to the forthcoming paper [6].
Appendix A: Reflection groups and equivariant perturbations

We provide a general framework to motivate the definition of the functions $\psi^m_q$ and $\psi_q^m$ from Sect. 5.2. We describe the construction at a more abstract level with the hope that it could be a useful tool to analyze infinite group problems in higher dimensions.

We follow the direction of [5] where the relevant arithmetics of the one-dimensional problem is captured by studying sets of additivity relations of the form $\pi(t_i) + \pi(y) = \pi(t_i + y)$ and $\pi(x) + \pi(r_i - x) = \pi(r_i)$, where the points $t_i$ and $r_i$ are breakpoints of a one-dimensional minimal valid function $\pi$. This is an important departure from the previous literature, which only uses additivity relations over non-degenerate intervals. The arithmetic nature of the problem comes into focus when one realizes that isolated additivity relations over single points are also important for studying extremality. These isolated additivity relations give rise to a subgroup of the group $\text{Aff}(\mathbb{R}^k)$ of invertible affine linear transformations of $\mathbb{R}^k$ as follows.

A.1 Reflection groups and their fundamental domains

For a point $r \in \mathbb{R}^k$, define the reflection $\rho_r : \mathbb{R}^k \to \mathbb{R}^k$, $x \mapsto r - x$. For a vector $t \in \mathbb{R}^k$, define the translation $\tau_t : \mathbb{R}^k \to \mathbb{R}$, $x \mapsto x + t$. We consider the reflections $\rho_r$ and translations $\tau_t$ as elements of the group $\text{Aff}(\mathbb{R}^k)$.

Given a set $R$ of points in $\mathbb{R}^k$ and a set $T$ of vectors in $\mathbb{R}^k$, we define the reflection group $\Gamma = \Gamma(R, T) = \langle \rho_r, \tau_t \mid r \in R, t \in T \rangle$. A group character of $\Gamma$ is a group homomorphism $\chi : \Gamma \to \mathbb{C}^\times$. The orbit of a point $x \in \mathbb{R}^k$ under the group $\Gamma \subseteq \text{Aff}(\mathbb{R}^k)$ is the set $\Gamma(x) = \{ \gamma(x) \mid \gamma \in \Gamma \}$. We extend this notation to subsets of $\mathbb{R}^k$: for a subset $X \subseteq \mathbb{R}^k$, $\Gamma(X) = \bigcup_{x \in X} \Gamma(x)$.

In the following, we assume that $R \neq \emptyset$, i.e., at least one of the generators is a reflection. The structure of the group $\Gamma$ is easy to describe completely. The following lemma, which appeared in [5] for $k = 1$, summarizes the structure of this group and generalizes easily from [5].

Lemma A.1 Let $r_1 \in R$. Then the group $\Gamma = \Gamma(R, T) = \langle \rho_r, \tau_t \mid r \in R, t \in T \rangle$ is the semidirect product $\Gamma^+ \rtimes \langle \rho_{r_1} \rangle$, where the (normal) subgroup of translations is of index 2 in $\Gamma$ and can be written as

$$\Gamma^+ = \{ \tau_t \mid t \in Y \},$$

where $Y$ is the additive subgroup of $\mathbb{R}^k$

$$Y = \langle r - r_1, t \mid r \in R, t \in T \rangle \subseteq \mathbb{R}^k.$$ (14)

There is a unique group character $\chi : \Gamma \to \{ \pm 1 \} \subseteq \mathbb{C}^\times$ with $\chi(\rho) = -1$ for every reflection $\rho \in \Gamma$ and $\chi(\tau) = +1$ for every translation $\tau \in \Gamma$. 

© Springer
Definition A.2 A function $\psi : \mathbb{R}^k \rightarrow \mathbb{R}$ is called $\Gamma$-equivariant if it satisfies the equivariance formula

$$\psi(\gamma(x)) = \chi(\gamma)\psi(x) \quad \text{for} \ x \in \mathbb{R}^k \ \text{and} \ \gamma \in \Gamma. \quad (15)$$

We will use formula (15) to give an alternative derivation of the functions $\psi^{m}_{q}, \psi^{m}_{\infty}$ and $\psi^{m}_{q,\infty}$ defined in Sect. 5.2. These functions provide the perturbation functions when Theorem 3.13 is invoked in Sect. 5.3.

Observation A.3 Let $\Gamma = \Gamma(R, T)$ be a reflection group with $R \cap T \neq \emptyset$ and let $\psi$ be any $\Gamma$-equivariant function. Then, $\rho_{0} \in \Gamma$ and $\psi(0) = 0$.

Proof Let $r \in R \cap T$; then $\rho_{0} = r_{r} \circ \tau_{0}$. Also, we have $\psi(0) = \psi(\rho_{0}(0)) = \chi(\rho_{0})\psi(0) = -\psi(0)$; hence, $\psi(0) = 0$. \hfill $\square$

It follows from Observation A.3 that when $R \cap T \neq \emptyset$ and $\psi$ is $\Gamma$-equivariant, we have $\psi \equiv 0$ on all of $\Gamma(0)$. If we restrict ourselves to continuous $\Gamma$-equivariant functions and $Y$ defined in (14) is dense in $\mathbb{R}^k$, then $\psi \equiv 0$ is the unique $\Gamma$-equivariant function. On the other hand, when $Y$ has inherent discreteness properties, which we make precise in the following discussion, we can construct many non-trivial continuous $\Gamma$-equivariant functions. To do so, we only need to construct a function on a subset of $\mathbb{R}^k$.

Definition A.4 A fundamental domain of a reflection group $\Gamma$ is a subset of $\mathbb{R}^k$ that is a system of representatives of the orbits.

Given a reflection group $\Gamma$ for $k = 1$, if the group $Y$ from (14) in Lemma A.1 is discrete, a fundamental domain of $\Gamma$ can be chosen as a certain closed interval. In higher dimensions, when $Y$ is discrete, the fundamental domain is no longer a closed set. Even so, it is easy to describe the closure of a fundamental domain. This is made concrete in the following discussion and Lemma A.5.

A well known fact is that for any discrete subgroup $\Lambda$ of $\mathbb{R}^k$ there exists a finite set of vectors $t_1, \ldots, t_\ell \in \mathbb{R}^k$ such that $\Lambda = \langle t_1, \ldots, t_\ell \rangle_{\mathbb{Z}}$. These vectors are called the basis of $\Lambda$. We say that $\Lambda$ is a lattice of the linear subspace $\langle t_1, \ldots, t_\ell \rangle_{\mathbb{R}}$. The set $V_{\Lambda} = \{ \sum_{i=1}^{\ell} \lambda_i t_i \mid 0 \leq \lambda_i \leq 1 \}$ is called the closed fundamental parallelepiped of $\Lambda$ with respect to the basis $t_1, \ldots, t_\ell$. Define $t = \sum_{i=1}^{\ell} t_i$ and set $M := \max\{ t \cdot x \mid x \in V \} = t \cdot t$. Define $V_{\Lambda}^{+} = \{ x \in V \mid t \cdot x \leq \frac{M}{2} \}$ and $V_{\Lambda}^{-} = \{ x \in V \mid t \cdot x \geq \frac{M}{2} \}$. (These definitions are of course with respect to the particular basis $\{ t_1, \ldots, t_\ell \}$; the basis will usually be fixed in a particular context).

A mixed-lattice is a subgroup $Y \subseteq \mathbb{R}^k$ such that $Y = \Lambda + L$ where $\Lambda$ is a lattice of a linear subspace $L'$ of $\mathbb{R}^k$, $L$ is a linear subspace of $\mathbb{R}^k$, and $L'$ and $L$ are complementary subspaces, i.e., $\mathbb{R}^k = L' + L$ and $L \cap L' = \{0\}$.

Lemma A.5 Let $\Gamma = \Gamma(R, T)$ be a reflection group with $\emptyset \subsetneq R \subsetneq T$ such that the corresponding $Y$ from (14) is a mixed-lattice, i.e., $Y = \Lambda + L$ and let $t_1, \ldots, t_\ell \in \mathbb{R}$ be a basis of $\Lambda$. Let $L' = \langle t_1, \ldots, t_\ell \rangle_{\mathbb{R}}$. Let $V_{\Lambda}^{+}$ be defined with respect to this basis. Then there exists a fundamental domain $\bar{V}$ for $\Gamma$ such that $\text{int}_{L'}(V_{\Lambda}^{+}) \subseteq \bar{V} \subseteq V_{\Lambda}^{+}$. 

\textcopyright Springer
Translating the closure of the fundamental domain, $V_3^+ = 0$ (blue triangle), by $r_t$ for $t \in \Lambda q_+/\Lambda_3 = \frac{1}{q} \mathbb{Z}^2$ gives the triangles labeled with +. Reflections by $r_r$ for $r \in \frac{1}{q} \mathbb{Z}^2$ take these triangles to the triangles labeled with −. Right the case $\Gamma q_+/\Lambda_3$. Translating the closure of the fundamental domain, $V^+_3$ (blue line segment), by $r_t$ for $t \in L_3$ gives the diagonal strip, labeled +, containing the fundamental domain. Further translations by $r_t$ for $t \in \Lambda q_+/\Lambda_3$ give the remaining diagonal strips labeled +. The reflections $r_r$ in $\Gamma q_+/\Lambda_3$ then take these strips to the strips labeled − (color figure online).

**Proof** We first show that $V^+_A$ contains a representative for every point $x$ in $\mathbb{R}^k$. Let $x = \sum_{i=1}^\ell \lambda_i t^i + p$ for some $0 \leq \lambda_i \leq 1$, $p \in Y$. We will show that $\gamma(x) \in V^+_A$ for some $\gamma \in \Gamma$. Let $x' = \sum_{i=1}^\ell \lambda_i t^i$ and let $t = \sum_{i=1}^\ell t^i$. If $x' \in V^+_A$, then we are done by taking $\gamma = \tau_{-p}$. Otherwise, $t \cdot x' > \frac{M}{2}$. Consider $\tau_t \circ \rho_0(x') = t - x' = \sum_{i=1}^\ell (1 - \lambda_i) t^i$. By Observation A.3, $\rho_0 \in \Gamma$ and so $\gamma = \tau_t \circ \rho_0 \in \Gamma$. Further, $t \cdot (t - x') = M - t \cdot x' < \frac{M}{2}$, and hence $\gamma(x) = t - x' \in V^+_A$. Hence, $V^+_A$ contains a representative for every point in $\mathbb{R}^k$.

Next we show that every point $x \in \text{int}_{L'}(V^+_A)$ is a unique representative in $V^+_A$ because for any non-trivial $\tau_t \in \Gamma^+$, $\tau_t(x) \notin V_A$, and for any $r \in R \subseteq T$, $\rho_r(x) = \tau_r \circ \rho_0(x)$ lies in $\Gamma^+ \cap \text{int}_{L'}(V^+_A)$, which does not intersect $V^+_A$ (recall that $\Gamma^+$ is the subgroup defined in (13) for $\Gamma$).

The following lemma explains how to construct $\Gamma$-equivariant functions using the fundamental domain.

**Lemma A.6** (Construction of $\Gamma$-equivariant functions) Let $\Gamma = \Gamma(R, T)$ be a reflection group with $\emptyset \subset R \subseteq T$ such that the corresponding $Y$ from (14) is a mixed-lattice, i.e., $Y = \Lambda + L$ and let $t^1, \ldots, t^\ell$ be a basis of $\Lambda$. Let $L' = \langle t^1, \ldots, t^\ell \rangle_{\mathbb{R}}$. Let $V^+_A$ be defined with respect to this basis. Let $\psi : V^+_A \rightarrow \mathbb{R}$ be any function such that $\psi|_{\partial L'(V^+_A)} = 0$, where $\partial L'(V^+_A)$ denotes the boundary of $V^+_A$ with respect to the linear subspace $L'$. Then the equivariance formula (15) gives a well-defined extension of $\psi$ to all of $\mathbb{R}^k$.

Figures 8 and 10 illustrate this construction.

**Proof** By Lemma A.5, $V^+_A$ contains a fundamental domain. Since $\text{int}_{L'}(V^+_A)$ has unique representatives for the orbits of $\Gamma$ and $\psi = 0$ on the boundary $\partial L'(V^+_A)$, the extension is well-defined. 

Springer
A.2 Deriving the perturbation functions $\psi_{q,\square}^m, \psi_{q,\square}^m$ using equivariance formulas

In [5], the authors use $\Gamma = \langle \rho_G, \tau_g \mid g \in \frac{1}{q}\mathbb{Z} \rangle$, where $Y = \Lambda = \frac{1}{q}\mathbb{Z}$. Using the lattice basis $\{\mathbf{t}^1 = \frac{1}{q}\},$ we obtain the fundamental parallelepiped $V_\Lambda = [0, \frac{1}{q}]$. In this one-dimensional case, $V_\Lambda^+$ is actually a fundamental domain for $\Gamma$.

We proceed similarly with two different reflection groups in dimension two. We first consider the reflection group $\Gamma_{q,\square}^+ = \langle \rho_G, \tau_g \mid g \in \frac{1}{q}\mathbb{Z} \rangle$ generated by reflections and translations corresponding to all possible vertices of $\mathcal{P}_q$; see Fig. 10 (left). The corresponding lattice $V_{q,\square}^+ = \Lambda_{q,\square} = \frac{1}{q}\mathbb{Z}^2$. Using the lattice basis $\{\mathbf{t}^1 = (1/q), \mathbf{t}^2 = (1/q)\}$, we obtain the fundamental parallelepiped $V_{q,\square} = [0, \frac{1}{q}]^2$. We make this particular choice of fundamental domain in part because $V_{q,\square}^+ \subseteq \mathcal{P}_q$ and $\Gamma_{q,\square}(V_{q,\square}^+) \subseteq \mathcal{P}_q$.

By Lemma A.6, the extension of $\psi_{q,\square}^m$ to $\mathbb{R}^2$ via the equivariance formula (15) is well-defined. This is an alternative description for the function $\psi_{q,\square}^m$ defined in Sect. 5.2; refer back to Fig. 8 (left) for an illustration.

One possible choice of a fundamental domain for $\Gamma_{q,\square}$ is

$$\tilde{V}_{q,\square} = \text{int}(0\square) \cup \left[\left(\frac{0}{q}\right), \left(\frac{1}{2q}\right)\right] \cup \left[\left(\frac{1}{2q}, \frac{1}{2}\right)\right] \cup \left[\left(0, \frac{1}{2q}\right)\right],$$

where $[x, y]$ and $(x, y)$ denote the closed and half open line segments, respectively, between $x$ and $y$. For our construction, only its closure, $V_{q,\square}^+ = 0\square$, matters.

Lemma A.7 The function $\psi_{q,\square}^m : \mathbb{R}^2 \to \mathbb{R}$ has the following properties:

(i) $\left.\psi_{q,\square}^m\right|_I = 0$ on all edges and vertices $I \in \mathcal{P}_{q,\square}$

(ii) $\psi_{q,\square}^m(\mathbf{x}) = -\psi_{q,\square}^m(\rho_G(\mathbf{x})) = -\psi_{q,\square}^m(\mathbf{g} - \mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^2$ and $\mathbf{g} \in \frac{1}{q}\mathbb{Z}^2$.

(iii) $\psi_{q,\square}(\mathbf{x}) = \psi_{q,\square}(\tau_g(\mathbf{x})) = \psi_{q,\square}(\mathbf{g} + \mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^2$ and $\mathbf{g} \in \frac{1}{q}\mathbb{Z}^2$.

(iv) Let $i = 1, 2$ or 3, and let $F \in \Delta \mathcal{P}_q$ be such that $p_i(F) \in \mathcal{P}_{q,\square}$. Then, $F \subseteq E(\psi_{q,\square}^m)$.

(v) $\psi_{q,\square}^m$ is continuous piecewise linear over $\mathcal{P}_{mq}$.

Proof Properties (i), (ii), (iii) follow directly from the equivariance formula (15). The function is continuous because it is continuous on the interior of each $I \in \mathcal{P}_{q,\square}$ by construction and because $\left.\psi_{q,\square}^m\right|_I = 0$ on all edges $I \in \mathcal{P}_{q,\square}$. Property (iv) follows from properties (i), (ii), and (iii) and the fact that $\text{vert}(\mathcal{P}_q) = \frac{1}{q}\mathbb{Z}^2$. Finally, the function is continuous piecewise linear by construction as well. \[\square\]
We next analyze \( \psi_{q,\mathbb{N}}^{m} \) from Sect. 5.2. Let \( \Gamma_{q,\mathbb{N}} = (\rho_{y}, \tau_{y} \mid y \in \mathbb{R}^{2}, 1 \cdot y \equiv 0 \pmod{\frac{1}{q}}) \supseteq \Gamma_{q,\mathbb{Z}} \) be the group generated by reflections and translations corresponding to all points on diagonal edges of \( \mathcal{P}_{q} \); see Fig. 10 (right). In this case, \( Y_{q,\mathbb{N}} = \Lambda_{q,\mathbb{N}} + L_{\mathbb{N}} \) where \( \Lambda_{q,\mathbb{N}} = \frac{1}{q} \mathbb{Z} \times \{0\} \) and \( L_{\mathbb{N}} \) are as defined in Definition 4.12. We choose the lattice basis \( (0, 1) \) such that \( \Lambda_{q,\mathbb{N}} \) has the fundamental parallelepiped \( V_{q,\mathbb{N}} = [(0, 0), (1/q, 0)] \) and hence \( V_{q,\mathbb{N}}^{+} = [(0, 0), (1/2q, 0)] \). (Note that we have simplified the notation, e.g., \( V_{\Lambda_{q,\mathbb{N}}} \) is now denoted by \( V_{q,\mathbb{N}}^{+} \).)

We consider an alternative description for the function \( \psi_{q,\mathbb{N}}^{m}, m \geq 3 \). This is done by setting \( \psi_{q,\mathbb{N}}^{m}(0, 0) = 0, \psi_{q,\mathbb{N}}^{m}(1/2q, 0) = 0 \), and for integer \( i \) with \( 1 \leq i < \frac{m}{2} \) we set \( \psi_{q,\mathbb{N}}^{m}(i/mq, 0) = 1 \). Then the function is interpolated over the vertices of \( \mathcal{P}_{mq} \) that lie in \( V_{q,\mathbb{N}}^{+} \). We extend the function to all of \( \mathbb{R}^{2} \) by applying the equivariance formula (15) (the extension is well-defined by Lemma A.6). This results in the continuous piecewise linear function \( \psi_{q,\mathbb{N}}^{m} \), defined in Sect. 5.2; refer back to Fig. 8 (right) for an illustration.

**Lemma A.8** The function \( \psi_{q,\mathbb{N}}^{m} : \mathbb{R}^{2} \rightarrow \mathbb{R} \) has the following properties:

1. \( \psi_{q,\mathbb{N}}^{m} \mid_{I} = 0 \) on all edges and vertices \( I \in \mathcal{P}_{q,\mathbb{N}}^{+} \).
2. \( \psi_{q,\mathbb{N}}^{m}(x) = -\psi_{q,\mathbb{N}}^{m}(\rho_{y}(x)) = -\psi_{q,\mathbb{N}}^{m}(y-x) \) for all \( x \in \mathbb{R}^{2} \) and \( y \in \mathbb{R}^{2} \) such that \( 1 \cdot y \equiv 0 \pmod{\frac{1}{q}} \).
3. \( \psi_{q,\mathbb{N}}^{m}(x) = \psi_{q,\mathbb{N}}^{m}(\tau_{y}(x)) = \psi_{q,\mathbb{N}}^{m}(y+x) \) for all \( x \in \mathbb{R}^{2} \) and \( y \in \mathbb{R}^{2} \) such that \( 1 \cdot y \equiv 0 \pmod{\frac{1}{q}} \).
4. Let \( i = 1, 2, \) or \( 3 \) and let \( F \in \Delta \mathcal{P}_{q} \) be such that \( p_{i}(F) \in \mathcal{P}_{q,\mathbb{N}}^{+} \). Then, \( F \subseteq E(\psi_{q,\mathbb{N}}^{m}) \).
5. \( \psi_{q,\mathbb{N}}^{m} \) is continuous piecewise linear over \( \mathcal{P}_{mq} \).

**Proof** Properties (i), (ii), (iii) follow directly from the equivariance formula (15). Property (iv) follows from properties (i), (ii), and (iii) and the fact that all faces of \( \mathcal{P}_{q,\mathbb{N}}^{+} \) are contained in the set \( \{ y \in \mathbb{R}^{2} \mid 1 \cdot y \equiv 0 \pmod{\frac{1}{q}} \} \). The function is continuous because the restriction to \( V_{q,\mathbb{N}}^{+} \) is continuous and the function vanishes on the relative boundary of \( V_{q,\mathbb{N}}^{+} \). Finally, the function is piecewise linear by construction as well.

### Appendix B: Genuinely k-dimensional functions

#### B.1 Preliminaries

In this section, we prove useful properties of a special class of functions called *genuinely k-dimensional* functions. In the process, we motivate our assumption in Theorems 1.8 and 1.9 that \( f \in \text{vert}(\mathcal{P}_{q}) \).

**Definition B.1** A function \( \theta : \mathbb{R}^{k} \rightarrow \mathbb{R} \) is *genuinely k-dimensional* if there does not exist a function \( \varphi : \mathbb{R}^{k-1} \rightarrow \mathbb{R} \) and a linear map \( T : \mathbb{R}^{k} \rightarrow \mathbb{R}^{k-1} \) such that \( \theta = \varphi \circ T \).
Genuinely $k$-dimensional functions were studied in [7]. We will show that $f$ must be a vertex of the complex $\mathcal{P}$ whenever $\pi$ is a minimal piecewise linear function over $\mathcal{P}$ that is genuinely $k$-dimensional. We will then show that it suffices to consider only genuinely $k$-dimensional functions. This is because if the function is not genuinely $k$-dimensional we can study the function in a lower dimension by instead studying its restriction to a linear subspace of $\mathbb{R}^k$.

We will need the following lemma, which is implied by Lemma 13 in [3] and is a consequence of Dirichlet’s Approximation Theorem for the reals.

**Lemma B.2** ([7]) Let $y \in \mathbb{R}^k$ be any point and $r \in \mathbb{R}^k \setminus \{0\}$ be any direction. Then for every $\epsilon > 0$ and $\lambda > 0$, there exists $w \in \mathbb{Z}^k$ such that $y + w$ is at distance less than $\epsilon$ from the half line $\{y + \lambda r \mid \lambda \geq \lambda\}$.

The proof of the next lemma is adapted from the proof of Claim 2 in [3]. For any linear subspace $M$ of $\mathbb{R}^k$, $\text{proj}_M(\cdot)$ will denote orthogonal projection onto $M$. Also $M^\perp$ will denote the orthogonal complement of $M$.

**Lemma B.3** Let $L$ be any linear subspace of $\mathbb{R}^k$. Then $\text{proj}_L(\mathbb{Z}^k)$ has the following form: there exists a linear subspace $L' \subseteq L$ (we allow the possibility $L' = \{0\}$) such that $\text{proj}_L(\mathbb{Z}^k) = \Lambda + D$, where $\Lambda$ is a lattice that spans $L' \perp \cap L$ and $D$ is a dense subset of $L'$.

**Proof** Let $\Lambda' = \text{proj}_L(\mathbb{Z}^k)$. Let $V_\epsilon$ be the linear subspace of $L$ spanned by the points in $\{y \in \Lambda' \mid \|y\| < \epsilon\}$. Notice that, given $\epsilon' > \epsilon'' > 0$, then $V_{\epsilon'} \supseteq V_{\epsilon''} \supseteq \{0\}$. Since $\dim(V_\epsilon)$ changes discretely as $\epsilon \to 0$, there exists $\epsilon_0 > 0$ such that $V_{\epsilon} = V_{\epsilon_0}$ for every $0 < \epsilon < \epsilon_0$. Let $L' = V_{\epsilon_0}$. Observe that $\Lambda' \cap L'$ is dense in $L'$ and $\Lambda = \text{proj}_{L' \perp \cap L}(\Lambda')$ is discrete (i.e., $B(0, \epsilon_0) \cap \Lambda = \{0\}$). Since $\Lambda$ is the projection of a subgroup of $\mathbb{R}^k$, it is also a subgroup and therefore it is a discrete subgroup, i.e., a lattice. We thus have the result using $D = \Lambda' \cap L'$. \qed

The following lemma can be found within the proof of Lemma 2.10 in [7] for the case where $L$ is a one-dimensional linear space.

**Lemma B.4** Suppose $\theta : \mathbb{R}^k \to \mathbb{R}$ is a subadditive function such that $\theta = 0$ on a linear space $L$. For any $x, y \in \mathbb{R}^k$ such that $x - y \in L$, we have $\theta(x) = \theta(y)$.

**Proof** Since $x - y \in L$, $\theta(x - y) = 0$. By subadditivity, $\theta(y) + \theta(x - y) \geq \theta(x)$, which implies $\theta(y) \geq \theta(x)$. Similarly, $\theta(x) \geq \theta(y)$, and hence we have equality. \qed

The following lemma is modified version of Lemma 2.10 from [7] to give detail about when we can choose a linear map $T$ that can be represented as a rational matrix. We assume Lipschitz continuity because this continuity is implicit in continuous piecewise linear functions.

**Lemma B.5** Let $\theta : \mathbb{R}^k \to \mathbb{R}$ be nonnegative, Lipschitz continuous, subadditive and periodic modulo the lattice $\mathbb{Z}^k$. Suppose there exist $r \in \mathbb{R}^k \setminus \{0\}$ and $\bar{\lambda} > 0$ such that $\theta(\lambda r) = 0$ for all $0 \leq \lambda \leq \bar{\lambda}$. Then $\theta$ is not genuinely $k$-dimensional, i.e., there exists a linear map $T : \mathbb{R}^k \to \mathbb{R}^{k-1}$ and a function $\varphi : \mathbb{R}^{k-1} \to \mathbb{R}$ such that $\pi = \varphi \circ T$. Furthermore, if $r \in \mathbb{Q}^k$, then $T$ can be represented by a rational matrix.
Proof Let the Lipschitz constant for \( \theta \) be \( K \), that is, \( |\theta(x) - \theta(y)| \leq K \|x - y\| \) for all \( x, y \in \mathbb{R}^d \).

We will begin by showing that \( \theta(\lambda r) = 0 \) for all \( \lambda \in \mathbb{R} \). Let \( \lambda' \in \mathbb{R} \).

Suppose that \( \lambda' > \lambda \) and let \( M \in \mathbb{Z}_+ \) such that \( 0 \leq \lambda'/M \leq \lambda \). From the hypothesis, we have that \( \theta(\lambda'Mr) = 0 \). By nonnegativity and subadditivity of \( \theta \) we see \( 0 \leq \theta(\lambda' r) \leq M \theta(\lambda'Mr) = 0 \), and therefore, \( \theta(\lambda' r) = 0 \). This shows that \( \theta(\lambda r) = 0 \) for all \( \lambda \geq 0 \).

Next suppose \( \lambda' < 0 \). By Lemma B.2, for all \( \epsilon > 0 \) there exists a \( w \in \mathbb{Z}^d \) such that \( \lambda' r + w \) is at distance less than \( \epsilon \) from the half line \( \{ \lambda' r + \lambda r \mid \lambda \geq -\lambda' \} = \{ \lambda r \mid \lambda \geq 0 \} \).

That is, there exists a \( \tilde{\lambda} \geq 0 \) such that \( \|\lambda' r + w - \tilde{\lambda} r\| \leq \epsilon \). Since \( \theta(\tilde{\lambda} r) = 0 \), by periodicity and then Lipschitz continuity, we see that \( 0 \leq \theta(\lambda' r) = \theta(\lambda' r + w) = \theta(\lambda' r + w) - \theta(\tilde{\lambda} r) \leq K \epsilon \). This holds for every \( \epsilon > 0 \) and therefore \( \theta(\lambda' r) = 0 \).

Thus, we have shown that \( \theta(\lambda r) = 0 \) for all \( \lambda \in \mathbb{R} \).

Let \( L = \{ \lambda r \mid \lambda \in \mathbb{R} \} \). By Lemma B.4, for any \( x, y \) such that \( x - y \in L \), we have \( \theta(x) = \theta(y) \).

We conclude that \( \theta = \phi \circ \text{proj}_{L^\perp} \) for some function \( \phi : \mathbb{R}^{k-1} \to \mathbb{R} \) and therefore \( \theta \) is not genuinely \( k \)-dimensional. Finally, if \( r \in \mathbb{Q}^d \), then \( \text{proj}_{L^\perp} \) can be represented by a rational matrix. \( \square \)

### B.2 Dimension reduction for functions that are not genuinely \( k \)-dimensional

We now show that it suffices to consider only genuinely \( k \)-dimensional functions for testing extremality of continuous piecewise linear functions.

**Remark B.6** Given a piecewise linear continuous valid function \( \xi : \mathbb{R} \to \mathbb{R} \) for the one-dimensional infinite group problem \( R_T(\mathbb{R}, \mathbb{Z}) \), Dey–Richard [11, Construction 6.1] consider the function \( \kappa : \mathbb{R}^2 \to \mathbb{R}, \kappa(x) = \xi(1 \cdot x) \), where \( 1 = (\begin{array}{c} 1 \\ 1 \end{array}) \), and show that \( \kappa \) is minimal and extreme if and only if \( \xi \) is minimal and extreme, respectively. If \( \xi \) has rational breakpoints in \( \frac{1}{q} \mathbb{Z} \) with \( q \in \mathbb{Z}_+ \), then \( \kappa \) belongs to our class of diagonally constrained continuous piecewise linear functions over \( \mathcal{P}_q \). However, these functions are not genuinely 2-dimensional, and as Dey–Richard point out, we can study the one-dimensional function \( \xi \) instead of the 2-dimensional function \( \kappa \). We call the function \( \kappa \) a diagonal embedding of \( \xi \).

The following two theorems can be found in [11] for the special case of diagonal embeddings. We also refer the interested reader to [12] where the authors exhibit a sequential merge procedure, creating extreme functions in higher dimensions from extreme functions in lower dimensions and vice versa.

**Lemma B.7** Let \( T : \mathbb{R}^k \to \mathbb{R}^\ell \) be a linear map. Suppose \( \pi : \mathbb{R}^k \to \mathbb{R} \) and \( \varphi : T \mathbb{R}^k \to \mathbb{R} \) satisfy \( \pi = \varphi \circ T \). Then \( \pi \) is minimal for \( R_T(\mathbb{R}^k, \mathbb{Z}^\ell) \) if and only if \( \varphi \) is minimal for \( R_{TT}(T \mathbb{R}^k, T \mathbb{Z}^\ell) \).

**Proof** (\( \Longleftrightarrow \)) Suppose \( \varphi \) is minimal for \( R_{TT}(T \mathbb{R}^k, T \mathbb{Z}^\ell) \). We demonstrate that \( \pi \) satisfies the criterion from Theorem 1.1 to be minimal.

1. For any \( z \in \mathbb{Z}^\ell, 0 = \varphi(Tz) = \pi(z) \).
2. For any \( x, y \in \mathbb{R}^k \) we have
\[
\pi(x) + \pi(y) - \pi(x + y) = \varphi(Tx) + \varphi(Ty) - \varphi(T(x + y)) \\
= \varphi(Tx) + \varphi(Ty) - \varphi(Tx + Ty) \geq 0.
\]

3. For any \( x \in \mathbb{R}^k \), we have
\[
\pi(x) + \pi(f - x) = \varphi(Tx) + \varphi(T(f - x)) = \varphi(Tx) + \varphi(Tf - Tx) = 1.
\]

Therefore \( \pi \) is minimal by Theorem 1.1.

\((\implies)\) Suppose \( \pi \) is minimal for \( R_T(\mathbb{R}^k, \mathbb{Z}^k) \). We demonstrate that \( \varphi \) satisfies the criterion from Theorem 1.1 to be minimal.

1. For any \( z \in \mathbb{Z}^k, 0 = \pi(z) = \varphi(Tz) \).
2. For any \( x, y \in T\mathbb{R}^k \), let \( \hat{x} \in T^{-1}x, \hat{y} \in T^{-1}y \). Then
\[
0 \leq \pi(\hat{x}) + \pi(\hat{y}) - \pi(\hat{x} + \hat{y}) = \varphi(x) + \varphi(y) - \varphi(x + y).
\]
3. Similarly, for any \( x \in T\mathbb{R}^k \), let \( \hat{x} \in T^{-1}x \). Then
\[
1 = \pi(\hat{x}) + \pi(f - \hat{x}) = \varphi(x) + \varphi(Tf - x).
\]

Therefore \( \varphi \) is minimal by Theorem 1.1. \( \square \)

**Lemma B.8** Let \( \pi: \mathbb{R}^k \to \mathbb{R} \) be a minimal valid function. Let \( T: \mathbb{R}^k \to \mathbb{R}^\ell \) be a linear map and let \( \varphi: T\mathbb{R}^k \to \mathbb{R} \) such that \( \pi = \varphi \circ T \). Then \( \pi \) is extreme for \( R_T(\mathbb{R}^k, \mathbb{Z}^k) \) if and only if \( \varphi \) is extreme for \( R_T(T\mathbb{R}^k, T\mathbb{Z}^k) \).

**Proof** (\( \implies \)) We prove the contrapositive. Suppose \( \varphi \) is not extreme for \( R_T(T\mathbb{R}^k, T\mathbb{Z}^k) \). Then, by Lemma 1.4, there exist distinct minimal valid functions \( \varphi^1, \varphi^2 \) for \( R_T(T\mathbb{R}^k, T\mathbb{Z}^k) \) such that \( \varphi = \frac{1}{2}(\varphi^1 + \varphi^2) \). But then \( \pi^1 = \varphi^1 \circ T \) and \( \pi^2 = \varphi^2 \circ T \) are distinct functions, and \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \). By Lemma B.7, \( \pi^1, \pi^2 \) are minimal for \( R_T(\mathbb{R}^k, \mathbb{Z}^k) \). Therefore \( \pi \) is not extreme.

(\( \iff \)) We again prove the contrapositive. Suppose that \( \pi \) is not extreme for \( R_T(\mathbb{R}^k, \mathbb{Z}^k) \). Then there exist distinct minimal valid functions \( \pi^1, \pi^2 \) for \( R_T(\mathbb{R}^k, \mathbb{Z}^k) \) such that \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \). Since \( \pi, \pi^1, \pi^2 \) are minimal by Lemma 1.4, \( \pi(0) = \pi^1(0) = \pi^2(0) = 0 \). Since \( E(\pi) \subseteq E(\pi^1), E(\pi^2) \) by Lemma 1.4, and \( 0 = \pi(x) + \pi(-x) - \pi(0) = \Delta\pi(x, -x) \) for all \( x \in T^{-1}(0) \), it follows that \( \pi^i(x) = -\pi^i(-x) \) for \( i = 1, 2 \). Since \( \pi^i \) are valid functions, \( \pi^i \geq 0 \), therefore we must have \( \pi^i(x) = 0 \) for all \( x \in T^{-1}(0) \). By Lemma B.4, \( \pi^i(x) = \pi^i(y) \) whenever \( x - y \in T^{-1}(0) \). Therefore, we must have \( \varphi^1, \varphi^2 \) such that \( \pi^1 = \varphi^1 \circ T \) and \( \pi^2 = \varphi^2 \circ T \). Since \( \pi^1, \pi^2 \) are distinct, the functions \( \varphi^1, \varphi^2 \) are distinct as well. Also since \( \pi = \frac{1}{2}(\pi^1 + \pi^2) \), we have \( \varphi = \frac{1}{2}(\varphi^1 + \varphi^2) \). By Lemma B.7, \( \varphi^1, \varphi^2 \) are minimal for \( R_T(T\mathbb{R}^k, T\mathbb{Z}^k) \). Therefore \( \varphi \) is not extreme. \( \square \)
Given any family of polyhedra $\mathcal{F}$ (not necessarily a polyhedral complex), we say a polyhedral complex $\mathcal{P}$ is a refinement of $\mathcal{F}$ if every polyhedron of $\mathcal{F}$ is a union of polyhedra from $\mathcal{P}$.

**Proposition B.9** (Dimension reduction) Let $\mathcal{P}$ be a pure and complete polyhedral complex in $\mathbb{R}^k$ that is periodic modulo $\mathbb{Z}^k$. Let $\pi : \mathbb{R}^k \to \mathbb{R}$ be a piecewise linear function over $\mathcal{P}$, such that $\pi$ is nonnegative, subadditive, periodic modulo $\mathbb{Z}^k$ and $\pi(0) = 0$. If $\pi$ is not genuinely $k$-dimensional, then there exists a natural number $0 \leq \ell < k$, a pure and complete polyhedral complex $\mathcal{X}$ in $\mathbb{R}^\ell$ that is periodic modulo $\mathbb{Z}^\ell$, a nonnegative and subadditive function $\phi : \mathbb{R}^\ell \to \mathbb{R}$ that is piecewise linear over $\mathcal{X}$, and a point $f' \in \mathbb{R}^\ell \setminus \mathbb{Z}^\ell$ with the following properties:

1. $\pi$ is minimal for $R_\ell(\mathbb{R}^k, \mathbb{Z}^k)$ if and only if $\phi$ is minimal for $R_\ell(\mathbb{R}^\ell, \mathbb{Z}^\ell)$.
2. $\pi$ is extreme for $R_\ell(\mathbb{R}^k, \mathbb{Z}^k)$ if and only if $\phi$ is extreme for $R_\ell(\mathbb{R}^\ell, \mathbb{Z}^\ell)$.

**Proof** Since $\pi$ is not genuinely $k$-dimensional, it follows by iteratively applying the definition of genuinely $k$-dimensional functions that there exist a number $0 \leq \ell < k$, a function $\varphi : \mathbb{R}^\ell \to \mathbb{R}$, and a linear map $T : \mathbb{R}^k \to \mathbb{R}^\ell$ such that $\varphi : \mathbb{R}^\ell \to \mathbb{R}$ is genuinely $\ell$-dimensional and $\pi = \varphi \circ T$. Since $\pi$ is nonnegative, $\varphi$ must also be nonnegative. Since $\pi$ is subadditive and $T$ is additive, $\varphi$ must be subadditive.

**Claim 1** $T \mathbb{Z}^k$ is a lattice that spans $\mathbb{R}^\ell$.

Since every linear map is a projection composed with an isomorphism, Lemma B.3 implies that there exists a linear subspace $L \subseteq \mathbb{R}^\ell$ such that $T \mathbb{Z}^k = \Lambda + D$, where $\Lambda$ is a lattice spanning $L^\perp$ and $D$ is dense in $L$. If $L = \{0\}$ then we are done. So we assume $\dim(L) \geq 1$. Since $\pi$ is continuous (it is piecewise linear over a locally finite polyhedral complex), and $T$ is linear map, it follows that $\varphi$ is continuous. Also, since $\pi$ vanishes over $\mathbb{Z}^k$, $\varphi$ vanishes over $T \mathbb{Z}^k$. But this implies that $\varphi$ vanishes over $D$, and thus over $L$. By Lemma B.4, $\varphi$ is constant on the affine subspaces parallel to $L$.

This contradicts the assumption that $\varphi$ is genuinely $\ell$-dimensional. This concludes the proof of Claim 1.

Let $U = \bigcup_{I \in \mathcal{P}} (I \cap [0, 1]^n)$. Since $\pi$ is piecewise linear over $\mathcal{P}$, $\pi$ is also piecewise linear over a refinement of $\mathcal{P}$, in particular, over the polyhedral complex $\bigcup_{I \in U, w \in \mathbb{Z}^k} \{I + w\}$, that is periodic modulo $\mathbb{Z}^k$. Since $T \mathbb{Z}^k$ is a lattice and for every $I \in U$, $TI$ is a polytope (it is the projection of the polytope $I$), we can find a refinement of the family of polytopes $\bigcup_{I \in U, w \in T \mathbb{Z}^k} \{TI + w\}$; we denote this refinement by $\mathcal{P}'$, which is a pure and complete polyhedral complex of $\mathbb{R}^\ell$. We observe that $\varphi$ is piecewise linear over $\mathcal{P}'$ and $\mathcal{P}'$ is a polyhedral complex that is periodic modulo $T \mathbb{Z}^k$.

Now simply find an invertible linear transformation $A : T \mathbb{Z}^k \to \mathbb{Z}^\ell$ and let $\phi := \varphi \circ A^{-1}$ be the piecewise linear function defined over the pure and complete polyhedral complex $\mathcal{X} := AP'$ and let $f' := A T f$. Then $f' \notin \mathbb{Z}^\ell$, since $1 = \pi(f) = \phi(f')$ and $\phi(\mathbb{Z}^\ell) = \pi(\mathbb{Z}^\ell) = 0$. The two properties now follow from Lemmas B.7 and B.8. □

**Remark B.10** (Dimension reduction) Using Proposition B.9, the extremality/minimality question for $\pi$ that is not genuinely $k$-dimensional can be reduced to the same question for a lower-dimensional genuinely $\ell$-dimensional function (so $\ell < k$). When $\mathcal{P}$ is a rational polyhedral complex, this reduction can be done algorithmically. The question of making this effective for the irrational case is beyond the scope of this paper.
B.3 The assumption of \( f \in \text{vert}(\mathcal{P}) \)

We will show that \( f \) is a vertex for any minimal continuous piecewise linear function that is genuinely \( k \)-dimensional.

**Theorem B.11** Let \( \mathcal{P} \) be a pure and complete polyhedral complex in \( \mathbb{R}^k \) that is periodic modulo \( \mathbb{Z}^k \). Let \( \theta : \mathbb{R}^k \to \mathbb{R} \) be minimal, piecewise linear function over \( \mathcal{P} \) that is genuinely \( k \)-dimensional. Then \( f \in \text{vert}(\mathcal{P}) \).

**Proof** For the sake of contradiction, suppose \( f \notin \text{vert}(\mathcal{P}) \). Therefore, there exists some \( I \in \mathcal{P} \) with \( f \in \text{rel int}(I) \) and the dimension of \( I \) is at least one. Since \( \pi \) is minimal, \( 0 \leq \pi \leq 1 \). Since \( \pi(f) = 1 \), \( \pi \leq 1 \), \( \pi \) is affine on \( I \) and \( f \in \text{rel int}(I) \), we have \( \pi(x) = 1 \) for all \( x \in I \). Now consider \( \pi \) on \( f - I \) and note that \( 0 \in f - I \). By symmetry, \( \pi(x) = 0 \) for all \( x \in f - I \). Since the dimension of \( I \) is at least one, there exists \( r \in (f - I) \setminus \{0\} \). But then \( \pi(\lambda r) = 0 \) for all \( \lambda \in [0, 1] \). Since \( \pi \) is continuous piecewise linear over \( \mathcal{P} \), by Lemma 1.4, it satisfies the hypotheses of Lemma B.5. Therefore, \( \pi \) is not genuinely \( k \)-dimensional, which is a contradiction. Therefore, we must have \( f \in \text{vert}(\mathcal{P}) \). \( \square \)

**Remark B.12** Using Proposition B.9 and Theorem B.11, we can achieve dimension reduction when \( f \notin \text{vert}(\mathcal{P}) \). Thus, although the results presented in this paper assume that \( f \in \text{vert}(\mathcal{P}) \), this assumption is actually not very restrictive.

B.4 Boundedness of cells for genuinely \( k \)-dimensional functions

In this subsection, we show that for genuinely \( k \)-dimensional minimal valid functions that are piecewise linear over a pure and complete polyhedral complex \( \mathcal{P} \) in \( \mathbb{R}^k \) that is periodic modulo \( \mathbb{Z}^k \), the cells of \( \mathcal{P} \) are full-dimensional bounded polytopes (so they cannot be unbounded polyhedra).

**Lemma B.13** Let \( r \in \mathbb{R}^k \) be any vector and let \( L = r^\perp \) be the orthogonal complement of the subspace spanned by \( r \). Let \( U \) be a compact convex set with nonempty interior in \( \mathbb{R}^k \). Then \( \text{proj}_L(U + \mathbb{Z}^k) \) is a closed set.

**Proof** Since orthogonal projections onto linear subspaces are linear operators, \( \text{proj}_L(U + \mathbb{Z}^k) = \text{proj}_L(U) + \text{proj}_L(\mathbb{Z}^k) \). Observe that \( \text{proj}_L(U) \) is also a compact convex set with nonempty interior with respect to \( L \). By Lemma B.3, there exists a linear subspace \( L' \subseteq L \) such that \( \text{proj}_L(\mathbb{Z}^k) = \Lambda + D \), where \( \Lambda \) is a lattice that spans \( L'^\perp \cap L \) and \( D \) is a dense subset of \( L' \). Since \( \text{proj}_L(U) \) is convex with nonempty interior, \( \text{proj}_L(U) + D = \text{proj}_L(U) + L' \). Let \( U' \) be the orthogonal projection of \( \text{proj}_L(U) \) onto \( L'^\perp \cap L \); so \( U' \) is compact convex set. Thus, we have

\[
\text{proj}_L(U + \mathbb{Z}^k) = \text{proj}_L(U) + \text{proj}_L(\mathbb{Z}^k) \\
= \text{proj}_L(U) + \Lambda + D \\
= \text{proj}_L(U) + L' + \Lambda \\
= U' + L' + \Lambda.
\]
Since $U'$ is a compact set and $\Lambda$ is a closed set, $U' + \Lambda$ is closed (see, e.g., [2] Lemma 5.3 (4)). Moreover, $U' + \Lambda \subseteq L'_{\perp} \cap L$. Therefore, $U' + \Lambda + L'$ is closed.

\hfill \Box

Let $H := [0, 1]^k$ denote the unit hypercube.

**Lemma B.14** Let $\mathcal{P}$ be a locally finite polyhedral complex that is periodic modulo $\mathbb{Z}^k$. Then for any full-dimensional polyhedron $I \in \mathcal{P}$, the set $I + \mathbb{Z}^k$ is a finite union of the form $\bigcup_{j \in J} (I_j + \mathbb{Z}^k)$ where $J$ is a finite index set and each $I_j$ is a full-dimensional polytope contained in $H$.

**Proof** We can take $I_j$ to be all full-dimensional polytopes contained in $(I + \mathbb{Z}^k) \cap H$. There are only finitely many of these polytopes by the locally finite property of $\mathcal{P}$ [see Definition 3.1 (iv)]. \hfill \Box

**Lemma B.15** Let $\theta : \mathbb{R}^k \rightarrow \mathbb{R}$ be a piecewise linear minimal valid function over a polyhedral complex $\mathcal{P}$ that is pure, complete and periodic modulo the lattice $\mathbb{Z}^k$. If $\theta$ is genuinely $k$-dimensional, then the cells of $\mathcal{P}$ and $\Delta \mathcal{P}$ are full-dimensional polytopes.

**Proof** Suppose to the contrary that a cell $I^*$ has a recession direction $r$. Let $L$ be the linear subspace orthogonal to $r$, i.e., $L = \langle r \rangle_{\perp}$. Let $U = \bigcup \{I \in \mathcal{P} \mid r \text{ is a recession direction for } I\}$. Define $S = \text{proj}_L(U)$.

**Claim 1** $S = L$.

First, notice that $H \cap \mathcal{P}$ contains finitely many full-dimensional polytopes by the local finiteness of $\mathcal{P}$. Combining this observation with Lemma B.14, we can express $U = \bigcup_{j \in J} (I_j + \mathbb{Z}^k)$ where $J$ is a finite index set and each $I_j$ is a full-dimensional polytope. Therefore, $S = \text{proj}_L(U) = \bigcup_{j \in J} \text{proj}_L(I_j + \mathbb{Z}^k)$, which is a finite union of closed sets by Lemma B.13. Therefore, $S$ is closed. The set $S$ is nonempty because $I^*$ has recession direction $r$. If $S \neq L$, then there exists a boundary point $x$ of $S$ (considered as a subset of $L$). Thus, there exist $Q_0 \in \mathcal{P}$ and $y \in Q_0$ such that $x = \text{proj}_L(y)$ and $Q_0$ has $r$ as a recession direction. Moreover, we can choose $y$ so that $y$ is in the relative interior of a face $F_0 \subseteq Q_0$ where $F_0$ also has $r$ as a recession direction. Let $Q_1, \ldots, Q_p \in \mathcal{P}$ be the cells that also have $F_0$ as their face (using the local finiteness of $\mathcal{P}$). We set $p = 0$ if $F_0 = Q_0$. Since $\mathcal{P}$ is complete and $y \in \text{rel int}(F_0)$, we can choose $\delta > 0$ such that $B(y, \delta) \subseteq Q_0 \cup Q_1 \cup \cdots \cup Q_p$. Since $F_0$ is a face of each of these polyhedra, $r$ is a recession direction for each $Q_0, Q_1, \ldots, Q_p$. Thus, $B(y, \delta) \subseteq U$ and thus, $\text{proj}_L(B(y, \delta)) \subseteq S$. But $\text{proj}_L(y) = x$ and $x$ is a boundary point of $S$. This is a contradiction. Therefore, $S = L$. This concludes the proof of Claim 1.

Fix $x \in L = S$. Let $Q \in \mathcal{P}$ be the cell such that $x \in \text{proj}_L(Q)$ and $r$ is a recession direction of $Q$. Thus, there exists a constant $\lambda(x) \in \mathbb{R}$ such that $x + \mu r \in Q$ for all $\mu \geq \lambda(x)$. Since $\theta$ is bounded and affine over $Q$, $\theta$ must be constant on the half-line $x + \mu r$, $\mu \geq \lambda(x)$. Thus, there exists a constant $C(x)$ such that $\theta(x + \mu r) = C(x)$ for all $\mu \geq \lambda(x)$. We now show that $\theta(x + \mu r) = C(x)$ for all $\mu \in \mathbb{R}$. Let $\mu' < \lambda(x)$ and let $y = x + \mu' r$. By Lemma B.2, for all $\epsilon > 0$ there exists $w \in \mathbb{Z}^k$ such that $y + w$ is at distance less than $\epsilon$ from the half line $\{y + \mu r \mid \mu \geq \lambda(x) - \mu' \} = \{x + \lambda r \mid \lambda \geq \lambda(x)\}$. That is, there exists $\tilde{\lambda} \geq \lambda(x)$ such that $\|y + w - (x + \tilde{\lambda} r)\| \leq \epsilon$. Since
A similar calculation shows \( p_1(F(I, J, K)) = \{x \in I \mid \exists y \in J, z \in K \text{ such that } x + y = z\} \)

\[ = \{x \in \mathbb{R}^k \mid \exists y \in J, z \in K \text{ such that } x + y = z\} \cap I \]

\[ = \{z - y \mid y \in J, z \in K\} \cap I \]

\[ = (K + (-J)) \cap I. \]

A similar calculation shows \( p_2(F(I, J, K)) = (K + (-I)) \cap J. \) Finally,

\[ p_3(F(I, J, K)) = \{z \in K \mid \exists x \in I, y \in J \text{ such that } x + y = z\} \]

\[ = \{z \in \mathbb{R}^k \mid \exists x \in I, y \in J \text{ such that } x + y = z\} \cap K \]

\[ = \{x + y \mid x \in I, y \in J\} \cap K \]

\[ = (I + J) \cap K. \]

\[ \Box \]

**Appendix C: Additional proofs**

**C.1 Proofs of lemmas on polyhedral complexes**

**Proof of Proposition 3.3** First of all, we have

\[ p_1(F(I, J, K)) = \{x \in I \mid \exists y \in J, z \in K \text{ such that } x + y = z\} \]

\[ = \{x \in \mathbb{R}^k \mid \exists y \in J, z \in K \text{ such that } x + y = z\} \cap I \]

\[ = \{z - y \mid y \in J, z \in K\} \cap I \]

\[ = (K + (-J)) \cap I. \]

A similar calculation shows \( p_2(F(I, J, K)) = (K + (-I)) \cap J. \) Finally,

\[ p_3(F(I, J, K)) = \{z \in K \mid \exists x \in I, y \in J \text{ such that } x + y = z\} \]

\[ = \{z \in \mathbb{R}^k \mid \exists x \in I, y \in J \text{ such that } x + y = z\} \cap K \]

\[ = \{x + y \mid x \in I, y \in J\} \cap K \]

\[ = (I + J) \cap K. \]

\[ \Box \]

**Proof of Lemma 3.6** We show the 4 conditions of Definition 3.1.

(i) Since \( \emptyset \in \mathcal{P} \), we have \( F(\emptyset, \emptyset, \emptyset) = \emptyset \in \Delta \mathcal{P}. \)

(ii) Let \( I, J, K \in \mathcal{P} \). Let \( \hat{F} \) be a face of \( F(I, J, K). \) Write \( I, J, K \) as inequality systems as \( A_I x \leq b_I, A_J x \leq b_J, A_K x \leq b_K. \) Then

\[ F(I, J, K) = \{(x, y) \mid A_I x \leq b_I, A_J y \leq b_J, A_K (x + y) \leq b_K\}. \]

The face \( \hat{F} \) is obtained by setting certain inequalities to equalities. This corresponds to restricting to faces of \( I, J, K. \) Therefore, there exist \( I', J', K' \in \mathcal{P} \) such that \( F(I', J', K') = \hat{F}. \) Therefore \( \hat{F} \in \Delta \mathcal{P}. \)

(iii) Let \( I, J, K, I', J', K' \in \mathcal{P}. \) Then \( F(I, J, K) \cap F(I', J', K') = F(I \cap I', J \cap J', K \cap K'). \) Since \( \mathcal{P} \) is closed under intersection, \( I \cap I', J \cap J', K \cap K' \in \mathcal{P}. \) Therefore \( F(I \cap I', J \cap J', K \cap K') \in \Delta \mathcal{P}. \)

(iv) Since \( \mathcal{P} \) is locally finite, it follows that \( \Delta \mathcal{P} \) is locally finite.
Hence, $\Delta P$ is a polyhedral complex. Finally, consider any $(x, y) \in \mathbb{R}^k \times \mathbb{R}^k$. Let $I, J, K \in P$ such that $x \in I, y \in J, x + y \in K$. These faces $I, J, K$ exist since $P$ is complete in $\mathbb{R}^k$. Therefore, $(x, y) \in F(I, J, K) \in \Delta P$. Thus, $\Delta P$ is complete. Since it is a locally finite complete polyhedral complex, it is also pure. This follows from the following argument. Suppose to the contrary, there is a face $F$ in $\Delta P$ that is maximal but not full-dimensional. Let $(x, y) \in F$ be a point in the relative interior of $F$ and note that $(x, y)$ cannot be contained in any other face of $\Delta P$ by the maximality of $F$. By the locally finite property of $\Delta P$, there exists an open ball $B$ around $(x, y)$ such that $B$ intersects $\Delta P$ only in $F$. Since $B \cap F$ is a strict subset of $B$, this contradicts that $\Delta P$ is complete. $\square$
