Abstract

We study a chain of four interacting rotors (rotators) connected at both ends to stochastic heat baths at different temperatures. We show that for non-degenerate interaction potentials the system relaxes, at a stretched exponential rate, to a non-equilibrium steady state (NESS). Rotors with high energy tend to decouple from their neighbors due to fast oscillation of the forces. Because of this, the energy of the central two rotors, which interact with the heat baths only through the external rotors, can take a very long time to dissipate. By appropriately averaging the oscillatory forces, we estimate the dissipation rate and construct a Lyapunov function. Compared to the chain of length three (considered previously by C. Poquet and the current authors), the new difficulty with four rotors is the apparition of resonances when both central rotors are fast. We deal with these resonances using the rapid thermalization of the two external rotors.

1 Introduction

We consider a chain of 4 classical rotors interacting at both ends with stochastic heat baths at different temperatures. Under the action of such heat baths, many Hamiltonian systems are known to relax to an invariant probability measure called non-equilibrium steady state (NESS). In general, the explicit expression for this invariant measure is unknown, and the convergence rate depends on the nature of the system. For the model under consideration, we obtain a stretched exponential rate.

For several examples of Hamiltonian chains, properties of the NESS (e.g., thermal conductivity, validity of the Fourier law, temperature profile, . . .) have been studied numerically, perturbatively, or via some effective theories. See for example [2, 6, 13, 16, 18] for chains of rotors and [1–3, 14, 17, 18] for chains of oscillators. From a rigorous point of view however, the mere existence of an invariant measure is not evident, and has been proved only in special cases.

A lot of attention has been devoted to chains of classical oscillators with (nonlinear) nearest neighbor interactions. In such models, each oscillator has a position $q_i \in \mathbb{R}$ (we take one dimension for simplicity), is attached to the reference frame with a pinning potential $U(q_i)$, and interacts with its neighbors via some interaction potentials $W(q_{i+1} - q_i)$ and $W(q_i - q_{i-1})$.

It turns out that the properties of the chain depend crucially on the relative growth of $W$ and $U$ at high energy. In the case of (asymptotically) polynomial potentials, and for Markovian heat baths, it has been shown [4, 8–11, 21] that if $W$ grows faster than $U$, the system typically relaxes exponentially fast to a NESS. The convergence is fast because, thanks to the strong interactions, the sites in the bulk of the chain “feel” the heat baths effectively even though they are separated from them by other sites.

In the strongly pinned case, i.e., when $U$ grows faster than $W$, the situation is more complicated. When a given site has a lot of energy, the corresponding oscillator essentially feels only its pinning potential $U(q_i)$ and not the interaction. Assume $U(q) \propto q^{2k}$ with $k > 1$. An isolated oscillator pinned with a potential $U$ and with an energy $E$ oscillates with a frequency that grows like $E^{1/2-1/2k}$.

This scaling plays a central role, since the larger the energy at a site, the faster the corresponding $q_i$ oscillates. But then, the interaction forces with the sites $i + 1$ and $i − 1$ oscillate very rapidly and become ineffective at high energy. Therefore, a site (or a set of sites) with high energy tends to decouple from the rest of the chain, so that energy can be “trapped” in the bulk. This mechanism not only makes the convergence to the invariant measure slower, but it also makes the proof of its existence harder. The case where $W$ is quadratic is considered in [15]. There, Hairer and Mattingly show that if $U(q) \propto q^{2k}$ with $k$ sufficiently large, no exponential convergence to an invariant measure (if there is one) can take place. Moreover, they show that an invariant measure exists in the case of 3 oscillators when $k > 3/2$. The existence of a NESS for longer chains of oscillators remains an open problem when the pinning dominates the interactions.

Chains of rotors are in fact closely related to strongly pinned oscillator chains: The frequency of a rotor scales as $E^{1/2}$, where $E$ is its energy. This scaling corresponds that of an oscillator in the limit $k \rightarrow \infty$, for the pinning $U(q) \propto q^{2k}$ discussed above. In this sense, our chain of rotors behaves as a chain of oscillators in the limit of “infinite pinning”, which is some kind of worst-case scenario from the point of view of the asymptotic decoupling at high energy. On the other hand, the compactness of the position-space (it is a torus) in the rotor case is technically very convenient. The problems appearing with chains of strongly pinned oscillators are very similar to those faced with chains of rotors, and so are the ideas involved to solve them.

The existence of an invariant measure for the chain of 3 rotors has been proved in [5], as well as a stretched exponential upper bound of the kind $e^{-c\sqrt{T}}$ on the convergence rate. The methods, which involve averaging the rapid oscillations of the central rotor, are inspired by those of [15] for the chain of 3 oscillators.

In the present paper, we generalize the result of [5] to the case of 4 rotors, and obtain again a bound $e^{-c\sqrt{T}}$ on the convergence rate. The main new difficulty in this generalization is the presence of resonances among the two central rotors. When they both have a large energy, there are two fast variables and some resonant terms make the averaging technique developed in [5] insufficient. A
large portion of the present paper is devoted to eliminating such resonant terms by using the rapid thermalization of the external rotors.

It would be of course desirable to be able to work with a larger number of rotors. The present paper uses explicit methods to deal with the averaging phenomena. We hope that by crystallizing the essentials of our methods, longer chains can be handled in the same spirit.

We now introduce the model and state the main results. In §2, we study the behavior of the system when one of the two central rotors is fast, and construct a Lyapunov function in this region. In §3, we do the same in the regime where both central rotors are fast. In §4 we construct a Lyapunov function that is valid across all regimes, and in §5 we provide the technicalities necessary to obtain the main result.

1.1 The model

![Figure 1 – A chain of four rotors with two heat baths at temperatures T₁ and T₄.](image)

We study a model of 4 rotors, each given by a momentum \( p_i \in \mathbb{R} \) and an angle \( q_i \in T = \mathbb{R}/2\pi \mathbb{Z}, \) \( i = 1, \ldots, 4. \) We write in the sequel \( q = (q_1, \ldots, q_4) \in \mathbb{T}^4, \) \( p = (p_1, \ldots, p_4) \in \mathbb{R}^4, \) and \( x = (q, p) \in \Omega, \) where \( \Omega = \mathbb{T}^4 \times \mathbb{R}^4 \) is the phase space of the system. We consider the Hamiltonian

\[
H(x) = \sum_{i=1}^{4} \frac{p_i^2}{2} + W_L(q_2 - q_1) + W_C(q_3 - q_2) + W_R(q_3 - q_4),
\]

where \( W_I : T \to \mathbb{R}, I = L, C, R \) (standing for left, center and right) are smooth \( 2\pi \)-periodic interaction potentials.

**Convention:** Unless specified otherwise, the arguments of the potentials are always as above, namely \( W_L = W_L(q_2 - q_1), W_C = W_C(q_3 - q_2) \) and \( W_R = W_R(q_3 - q_4). \) The same applies to any function with index L, C and R. Note that the argument for R is \( q_3 - q_4 \) (and not \( q_4 - q_3 \)) since this choice will lead to more symmetrical expressions between the sites 1 and 4.

To model the interaction with two heat baths, we add at each end of the chain a Langevin thermostat at temperature \( T_b > 0, \) with dissipation constant \( \gamma_b > 0, b = 1, 4. \) Introducing the derivative of the potentials \( w_1 = W'_I, I = L, C, R, \) the main object of our study is the SDE:

\[
\begin{align*}
\dot{q}_i &= p_i \, dt, \quad i = 1, \ldots, 4, \\
\dot{p}_1 &= (w_L - \gamma_1 p_1) \, dt + \sqrt{2\gamma_1 T_1} \, dB_1^1, \\
\dot{p}_2 &= (w_C - w_L) \, dt, \\
\dot{p}_3 &= -(w_C + w_R) \, dt, \\
\dot{p}_4 &= (w_R - \gamma_4 p_4) \, dt + \sqrt{2\gamma_4 T_4} \, dB_4^1,
\end{align*}
\]

where \( B_i^1, B_i^2 \) are independent standard Brownian motions. The generator of the semigroup associated to (1.2) reads

\[
L = \sum_{i=1}^{4} p_i \partial_{q_i} + w_L \cdot (\partial_{p_1} - \partial_{p_2}) + w_C \cdot (\partial_{p_2} - \partial_{p_3}) + w_R \cdot (\partial_{p_4} - \partial_{p_3})
+ \sum_{b=1,4} (-\gamma_b p_b \partial_{p_b} + \gamma_b T_b \partial_{p_b}^2).
\]

Remark 1.1. In contrast to [5], we do not allow for the presence of pinning potentials \(U(q_i)\) and of constant forces at the ends of the chain. While we believe that the main result still holds with such modifications, there is a specific part of the proof that would require modifications, which we are currently unable to provide (see Remark 3.13).

We consider the measure space \((\Omega, B)\), with the Borel \(\sigma\)-field \(B\) over \(\Omega\). The coefficients in (1.2) are globally Lipschitz, and therefore the solutions are almost surely defined for all times and all initial conditions. We denote the transition probability of the corresponding Markov process by \(P^t(x, \cdot)\), for all \(x \in \Omega\) and \(t \geq 0\).

1.2 Main results

We will often refer to the sites 1 and 4 as the outer (or external) rotors, and the site 2 and 3 as the central rotors. We require the interactions from the inner rotors to the outer rotors to be non-degenerate in the following sense:

Assumption 1.2. We assume that for \(I = L, R\) and for each \(s \in T\), at least one of the derivatives \(w^{(k)}_I(s), k \geq 1\) is non-zero.

This assumption is not very restrictive. In particular, it holds if all the potentials consist of finitely many nonconstant Fourier modes.

Our main result is a statement about the speed of convergence to a unique stationary state of the system (1.2). In order to state it, we introduce for each continuous function \(f : \Omega \to (0, \infty)\) the norm \(\|\cdot\|_f\) on the space of signed Borel measures on \(\Omega\):

\[
\|\nu\|_f = \sup_{|g| \leq f} \int_{\Omega} gd\nu.
\]

If \(f \equiv 1\), we retrieve the total variation norm.

Theorem 1.3 (NESS and rate of convergence). Under Assumption 1.2, the Markov process defined by (1.2) satisfies:

(i) The transition probabilities \(P^t(x, dy)\) have a \(C^\infty((0, \infty) \times \Omega \times \Omega)\) density \(p^t(x, y)\).

(ii) There is a unique invariant measure \(\pi\), and it has a smooth density.

(iii) For all \(0 \leq \theta_1 < \min(1/T_1, 1/T_4)\) and all \(\theta_2 > \theta_1\), there exist constants \(C, \lambda > 0\) such that for all \(x = (q_1, q_2, \ldots, q_4) \in \Omega\) and all \(t \geq 0\),

\[
\|P^t(x, \cdot) - \pi\|_\theta H \leq Ce^{\theta_2 H(x)}e^{-\lambda t/2}. \tag{1.4}
\]

At thermal equilibrium, namely when \(T_1 = T_4 = 1/\beta\) for some \(\beta > 0\), the invariant measure is the Gibbs distribution with density \(e^{-\beta H(x)}/Z\), where \(Z\) is a normalization constant.

Theorem 1.3 will be proved in §5 with help of results of [7] and the existence of a Lyapunov function, the properties of which are stated in

Theorem 1.4 (Lyapunov function). Let \(0 < \theta < \min(1/T_1, 1/T_4)\). Under Assumption 1.2, there is a function \(V : \Omega \to [1, \infty)\) satisfying:

(i) There are constants \(c_1 > 0\) and \(a \in (0, 1)\) such that

\[
1 + e^{\theta H} \leq V \leq c_1(e^{|p_2|a} + e^{|p_3|a})e^{\theta H}. \tag{1.5}
\]

(ii) There are a compact set \(K\) and constants \(c_2, c_3 > 0\) such that

\[
LV \leq c_2 1_K - \varphi(V), \tag{1.6}
\]

with \(\varphi : [1, \infty) \to (0, \infty)\) the increasing, concave function defined by

\[
\varphi(s) = \frac{c_3 s}{2 + \log(s)}. \tag{1.7}
\]
Most of the paper will be devoted to proving the existence of such a Lyapunov function.

**Remark 1.5.** We assume throughout that $T_1$ and $T_4$ are strictly positive. While the conclusions of Theorem 1.4 remain true for $T_1 = T_4 = 0$, and for any $\theta > 0$, part of the argument has to be changed in this case, as sketched in Remark 3.17. The positivity of the temperatures is, however, essential for Theorem 1.3; at zero temperature, the system is not irreducible, and none of the conclusions of Theorem 1.3 hold.

### 1.3 Overview of the dynamics

To gain some insight into the strategy of the proof, we illustrate some essential features of the dynamics (1.2). Since the exterior rotors (at sites 1 and 4) are directly damped by the $-\gamma_b p_b \, dt$ terms in (1.2), we expect their energy to decrease rapidly with large probability. More specifically, for $w$ (the force value) when it is large. Therefore, the external rotors recover very fast from thermal fluctuations, and will not be hard to deal with.

On the other hand, the central rotors are not damped directly, and feel the dissipative terms of (1.2) only indirectly, by interacting with the outer rotors. The interesting issue appears when the energy of the system is very large and mostly concentrated in one or both of the central rotors. If most of the energy is at site 2 (meaning that $|p_2|$ is much larger than all other momenta), the corresponding rotor spins very rapidly, i.e., $q_2$ moves very rapidly on $\mathbb{T}$. But then, the interaction forces $w_L(q_2 - q_1)$ and $w_C(q_3 - q_2)$ oscillate rapidly, which causes the site to essentially decouple from its neighbors. The same happens when most of the energy is at site 3, when $w_C(q_3 - q_2)$ and $w_R(q_3 - q_4)$ oscillate rapidly. And when both $|p_2|$ and $|p_3|$ are large and much larger than $|p_1|$ and $|p_4|$, the forces $w_L(q_2 - q_1)$ and $w_R(q_3 - q_4)$ are highly oscillatory, so that the central two rotors almost decouple from the outer ones (the force $w_C$ might or might not oscillate depending on $p_2$ and $p_3$).

This asymptotic decoupling is the interesting feature of the model: if the central rotors do not recover sufficiently fast from thermal fluctuations, the energy of the chain could grow (in expectation value) without bounds. Our results show that this does not happen.

Figure 2 illustrates the evolution\(^1\) of the momenta at two different time scales, starting with $p(0) = (50, 20, 30, 40)$. The upper graph shows that indeed $p_1$ and $p_4$ decrease very fast, and the lower graph indicates that $p_2$ and $p_3$ remain large for a significantly longer time, but eventually also decrease. Since for this initial condition $p_3$ is larger than $p_2$, the force $w_R$ oscillates faster than $w_L$. Therefore, $p_3$ couples less effectively to the outer rotors (where the dissipation happens) than $p_2$, and hence $p_3$ decreases more slowly.

If one were to look at these trajectories for much longer times, one would eventually observe some fluctuations of arbitrary magnitude, followed by new recovery phases. But large fluctuations are very rare.

Since the system is rapidly driven to small $p_1$, $p_4$, it is really the dynamics of $(p_2, p_3)$ that plays the most important role. We will often argue in terms of the 8-dimensional dynamics projected onto the $p_2p_3$-plane. We illustrate some trajectories in this plane for several initial conditions in Figure 3. To make the illustration readable, we used a very small temperature, so that the picture is dominated by the deterministic dynamics.

The typical trajectory is as follows. Starting with some large $|p_2|$ and $|p_3|$, the slower of the two central rotors is damped faster than the other, so that the projection drifts rapidly towards one of the axes. This leads to a regime where only one of the central rotors is fast, while the other is essentially thermalized. The energy in this fast rotor is gradually dissipated, so that the orbit follows the axis towards the origin.

\(^1\) The numerical algorithm used in this paper is based on the one described in [16]. The time step is either $10^{-2}$ or $10^{-3}$ depending on the situation.
The evolution of the momenta $p_1, \ldots, p_4$, for $\gamma_1 = \gamma_4 = 1$, $T_1 = 1$, $T_4 = 10$, $q(0) = (0, 0, 0, 0)$ and $p(0) = (50, 20, 30, 40)$. The interaction potentials in the simulations here are $W_I = -\cos$ so that the forces are $w_I = \sin$, $I = L, C, R$.

The behavior that we observe in Figure 3 around the diagonal $p_2 = p_3$ far enough from the origin is easily explained: in the “center of mass frame” of the two central rotors, we simply see two interacting rotors that oscillate slowly in opposition, while being almost decoupled from the outer rotors. More precisely, introducing $Q = q_3 - q_2 \in \mathbb{T}$ and $P = p_3 - p_2 \in \mathbb{R}$, we see that $(Q, P)$ acts approximately as a mathematical pendulum with potential $2W_C$, plus some rapidly oscillating (and therefore weak) interactions with the outer rotors:

$$\dot{Q} = P, \quad \dot{P} = -2w_C(Q) + \text{weak interactions}.$$  

Typically, if at first the energy in the center of mass frame is not large enough to make a “full turn,” $Q$ oscillates slowly around a minimum of $W_C$, which corresponds to a back-and-forth exchange of momentum between 2 and 3, and explains the strips that we observe around the diagonal. The two central rotors are then gradually slowed down, until at some point the interaction with the external rotors tear them apart.

The picture in the absence of noise (that is, when $T_1 = T_4 = 0$, which is not covered by our assumptions) is quite different, due to some resonances. We discuss their nature in Appendix A. These resonances are washed away by the noise, and are therefore not visible here. They nevertheless play an important role in our computations, as we will see.
Figure 3 – The evolution of $p_2$ and $p_3$ for several initial conditions. The potentials are $W_1 = -\cos, I = L, C, R$. Furthermore, $\gamma_1 = \gamma_4 = 1$, $T_1 = 0.1$, and $T_4 = 0.4$. Each “×” sign indicates the beginning of a trajectory.

1.4 Strategy

In order to obtain rigorous results about the dynamics and construct a Lyapunov function, we will apply specific methods to each regime described above. We present them here in increasing order of difficulty.

• When a significant part of the energy is contained in the outer rotors, then as discussed above, the momenta of the two outer rotors essentially decrease exponentially fast. In this region, the Lyapunov function will be $e^{\theta H}$, and we will show that when $p_2^2 + p_4^2$ is large enough and $\theta < \min (1/T_1, 1/T_4)$, then $Le^{\theta H} \lesssim -e^{\theta H}$ (Lemma 4.1).

• When most of the energy is contained at just one of the central sites, namely at site $j = 2$ or $j = 3$, we will show that $Lp_j \sim -p_j^{-3}$ when averaged appropriately (Proposition 2.2). This corresponds to the neighborhood of the axes in Figure 3. This case is essentially treated as in [5]. In this region, we use a Lyapunov function $V_j \sim e^{p_{j} a + \frac{1}{2} p_{j}^2}$ (with $a \in (0, 1)$) such that $LV_j \lesssim -V_j/p_{j}^2$ (Proposition 2.4).

• When both $|p_2|$ and $|p_3|$ are large and hold most of the energy, we do not approximate the dynamics of $p_2$ and $p_3$ separately, but we consider instead the “central” Hamiltonian $H_c = \frac{p_2^2}{2} + \frac{p_3^2}{2} + W_L + W_C + W_R$. We show that when averaged properly, $LH_c \sim -p_2^{-2} - p_3^{-2}$ (Proposition 3.2). The Lyapunov function in this region is $V_c \sim H_c e^{\theta H_c}$, and we show (Proposition 3.5) that $LV_c \lesssim -V_c/H_c$. Showing that $LH_c \sim -p_2^{-2} - p_3^{-2}$ is the most difficult part of our proof. The averaging of the rapidly oscillating forces will prove to be insufficient due to some resonances, which manifest themselves for some rational values of $p_3/p_2$. We will consider separately the vicinity of the $p_2 = p_3$ diagonal, which is easy to deal with (Lemma 3.7), and the case where $|p_3 - p_2|$ is large, which requires substantially more work (§3.3). In the latter case, we will use the rapid thermalization of the external rotors in order to eliminate the resonant terms.

The factors $1/p_2^2$ and $1/H_c$ in $LV_j \lesssim -V_j/p_{j}^2$ and $LV_c \lesssim -V_c/H_c$ are the cause of the logarithmic contribution in (1.7), which makes the convergence to the NESS happen only at subexponential rate.
The final step (§4) is to combine $e^{\theta H}, V_2, V_3$ and $V_c$ (which each behave nicely in a given regime) to obtain a Lyapunov function $V$ that behaves nicely everywhere and satisfies the conclusions of Theorem 1.4.

1.5 The domains

Following the discussion above, we decompose $\Omega$ into several sub-regions. This decomposition only involves the momenta, and not the positions. All the sets in the decomposition are defined in the complement of a ball $B_R$ of (large) radius $R$ in $p$-space:

$$B_R = \mathbb{T}^4 \times \left\{ p \in \mathbb{R}^4 : \sum_{i=1}^{4} p_i^2 \leq R^2 \right\}.$$

For convenience, we consider only $R \geq \sqrt{2}$ (see Remark 1.6). We also use (large) integers $k, \ell$, and $m$ which will be fixed in §4, and we assume throughout that

$$1 \leq k < \ell < m . \quad (1.8)$$

The first regions we consider are along the $p_2$ and $p_3$ axes:

$$\Omega_2 = \Omega_2(k, R) = \left\{ x \in \Omega : p_2^2 > (p_1^2 + p_3^2 + p_4^2)^k \right\} \setminus B_R ,$$

$$\Omega_3 = \Omega_3(k, R) = \left\{ x \in \Omega : p_3^2 > (p_1^2 + p_2^2 + p_4^2)^k \right\} \setminus B_R . \quad (1.9)$$

The region $\Omega_2$ (resp. $\Omega_3$) corresponds to the configurations where most of the energy is concentrated at site 2 (resp. 3). The next region corresponds to the configurations where most of the energy is shared among the sites 2 and 3:

$$\Omega_c = \Omega_c(\ell, m, R) = \left\{ x \in \Omega : p_2^2 + p_3^2 > (p_1^2 + p_4^2)^m , p_2^2 > p_2^{2\ell} , p_3^2 > p_3^{2\ell} \right\} \setminus B_R \quad (1.10)$$

(The conditions $p_2^{2\ell} > p_2^2$ and $p_3^{2\ell} > p_3^2$ ensure that both $|p_2|$ and $|p_3|$ diverge sufficiently fast when $\|p\| \to \infty$ in $\Omega_c$). These regions are illustrated in Figure 4 and Figure 5. Note that $\Omega_2, \Omega_3, \Omega_c$ do intersect and do not cover $\Omega$. However, neglecting some $B_R$, they cover the $p_2p_3$-plane, which is where the determining part of the dynamics lies, as discussed above.

![Figure 4 – A projection of the domains $\Omega_2, \Omega_3, \Omega_c$. The spherical surface represents $\|p\| = C$ for some $C > R$.](image)
Remark 1.6. As a consequence of the restriction $R \geq \sqrt{2}$, we have $\Omega_j(k', R') \subset \Omega_j(k, R)$ for all $k' \geq k$, $R' \geq R$, and $j = 2, 3$. Therefore, if a bound holds for all $x \in \Omega_j(k, R)$, it also holds for all $x \in \Omega_j(k', R')$. Similarly, at fixed $\ell$, we have $\Omega_\ell(\ell, m', R') \subset \Omega_\ell(\ell, m, R)$ for all $m' \geq m$ and $R' \geq R$. This allows us to increase $k$, $m$, and $R$ as needed (but not $\ell$). We also observe immediately that for all $k, \ell, m$, and for $j = 2, 3$,  
\begin{equation} \lim_{R \to \infty} \inf_{x \in \Omega_j(k, R)} |p_j| = \infty, \tag{1.11} \end{equation} \begin{equation} \lim_{R \to \infty} \inf_{x \in \Omega_\ell(\ell, m, R)} |p_j| = \infty. \tag{1.12} \end{equation}

1.6 Notations

Since averaging functions that rapidly oscillate in time will play an important role, we introduce the $q_i$-average $\langle f \rangle_i = \frac{1}{2\pi} \int_0^{2\pi} f(s) dq_i$ of a function $f : \Omega \to \mathbb{R}$ over one period of $q_i$. The result is a function of $p$ and $\{q_j : j \neq i\}$. In the presence of a generic function $f : T \to \mathbb{R}$ of one variable, we write simply $\langle f \rangle = \frac{1}{2\pi} \int_0^{2\pi} f(s) ds$, which is a constant.

For any function $f : T \to \mathbb{R}$ satisfying $\langle f \rangle = 0$, one can find a unique integral $F : T \to \mathbb{R}$ such that $F' = f$ and $\langle F \rangle = 0$. More generally, we write $f[j]$ for the $j$th integral of $f$ that averages to zero.

Without loss of generality, we fix the additive constants of the potentials so that $\langle W_I \rangle = 0$, $I = L, C, R$. \tag{1.13} 

We also introduce two “effective dissipation constants”: 
\begin{equation} \alpha_2 = \gamma_1 \langle W_{L}^2 \rangle > 0, \quad \alpha_3 = \gamma_4 \langle W_{R}^2 \rangle > 0, \tag{1.14} \end{equation} 
where the positivity follows from Assumption 1.2. Note also that because of (1.13), there is no indeterminate additive constant in the $\alpha_j$.

Finally, throughout the proofs, $c$ denotes a generic positive constant that can be each time different. These constants are allowed to depend on the parameters and functions at hand, but not on the position $x$. We sometimes also use $c'$ to emphasize that the constant has changed.

2 When only one of the central rotors is fast

We consider the regime where either $|p_2|$ or $|p_3|$ (but not both) is much larger than all other momenta. The estimates for this regime are simple adaptations from [5], but we recall here the main ideas.

We start with some formal computations, thinking in terms of powers of $p_2$ (resp. $p_3$) only. Then, we will restrict ourselves to the set $\Omega_2(k, R)$ (resp. $\Omega_3(k, R)$) for some large enough $k$ and $R$, so that the other momenta are indeed “negligible” (see Lemma 2.3) compared to $p_2$ (resp. $p_3$).
2.1 Averaging with one fast variable

Assume that $|p_2|$ is much larger than the other momenta. We think in terms of the following fast-slow decomposition: the variables $q_1, q_3, q_4$ and $p$ evolve slowly, while $q_2$ evolves rapidly, since $q_2 = p_2$, and $p_2$ is large. In this regime, the variable $q_2$ swipes through $T$ many times before any other variable changes significantly. The dynamics for short times is

$$
p(t) \approx p(0), \quad q_i(t) \approx q_i(0), \quad i = 1, 3, 4, \quad (2.1)
$$

$$
q_2(t) \approx q_2(0) + p_2(0)t \quad (\text{mod } 2\pi).
$$

We consider an observable $f : \Omega \to \mathbb{R}$ and let $g$ be defined by

$$
Lf = g. \quad (2.2)
$$

Under the approximation (2.1), the quantity $g(x(t))$ oscillates very rapidly around its $q_2$-average $\langle g \rangle_2$, which is a function of the slow variables $q_1, q_3, q_4$ and $p$. We therefore expect the effective equation $Lf \approx \langle g \rangle_2$ to describe the evolution of $f$ over several periods of oscillations, and we now show how to give a precise meaning to this approximation.

Although the stochastic terms (which appear as the second-order part of the differential operator $L$) appear in the computations, they do not play an important conceptual role in this discussion; the rapid oscillations that we average are of dynamical nature and are present regardless of the stochastic forcing exerted by the heat baths.

The generator of the dynamics (2.1) is simply

$$
L_2 = p_2 \partial_{q_2}.
$$

Decomposing the generator $L$ defined in (1.3) as $L = L_2 + (L - L_2)$ and considering powers of $p_2$, we view $L_2$ as large, and $L - L_2$ as small. Note that for all smooth $h : \Omega \to \mathbb{R}$, we have $\langle L_2 h \rangle_2 = p_2 \langle \partial_{q_2} h \rangle_2 = 0$ by periodicity, so that the image of $L_2$ contains only functions with zero $q_2$-average. Consider next $G = \int (g - \langle g \rangle_2) dq_2$ (there is an integration constant $C(q_1, q_3, q_4, p)$ which we choose to our convenience). By construction, we have $L_2(G/p_2) = g - \langle g \rangle_2$, so that

$$
L \left( f - \frac{G}{p_2} \right) = \langle g \rangle_2 + (L_2 - L) \frac{G}{p_2}. \quad (2.3)
$$

By subtracting the “small” counterterm $G/p_2$ from $f$, we have managed to replace $g$ with its $q_2$-average in the right-hand side, plus some “small” correction. This procedure is what we refer to as averaging with respect to $q_2$, and it makes sense only in the regime where $|p_2|$ is very large. If $\langle g \rangle_2 = 0$ and $(L_2 - L)(G/p_2)$ is still oscillatory, the procedure must be repeated.

2.2 Application to the central momenta

We now apply this averaging method to the observable $p_2$, in the regime where $|p_2|$ is very large. By the definition of $L$, we find

$$
Lp_2 = w_C - w_L. \quad (2.4)
$$

We have $\langle w_C \rangle_2 = \langle w_L \rangle_2 = 0$. Moreover, $\partial_{q_2} W_C(q_3 - q_2) = -w_C(q_3 - q_2)$ and $\partial_{q_2} W_L(q_2 - q_1) = w_L(q_2 - q_1)$. Thus, in the notation above, $G = \int (w_C - w_L) dq_2 = -W_C - W_L$, and we introduce the new variable

$$
p_2^{(1)} = p_2 - \frac{G}{p_2} = p_2 + \frac{W_C + W_L}{p_2}. \quad (2.5)
$$
By (2.3), we obtain

\[ L p_2^{(1)} = -(L_2 - L) \left( \frac{W_C + W_L}{p_2} \right) = \frac{p_3 w_C - p_1 w_L}{p_2} + \frac{W_C w_L - W_L w_C + W_L w_L - W_C w_C}{p_2^2}. \]  

(2.6)

Observe that the right-hand side of (2.6) is still oscillatory, but now with an amplitude of order \(1/p_2\), which is much smaller than the amplitude of (2.4) when \(|p_2|\) is large. Furthermore, the right-hand side of (2.6) has zero mean, since \(\langle w_C \rangle_2 = \langle w_L \rangle_2 = 0\) and

\[ \langle W_C w_L - W_L w_C + W_L w_L - W_C w_C \rangle_2 = \frac{1}{2} \langle \partial_q^2 (W_C + W_L)^2 \rangle_2 = 0, \]

by periodicity. In order to see a net effect, we need to average again. We consider now the observable \(f = p_2^{(1)}\), and apply the same procedure. Instead of averaging the right-hand side of (2.6) in one step, we first deal only with the terms of order \(-1\) in \(p_2\), by introducing

\[ p_2^{(2)} = p_2^{(1)} + \frac{p_1 W_L + p_3 W_C}{p_2^2}. \]  

(2.7)

We postpone further computations to the proof of Proposition 2.2 below, and explain here the main steps. We will see that \(L p_2^{(2)}\) consists of terms of order \(-2\) and \(-3\) (by construction, the contribution of order \(-1\) disappears). The terms of order \(-2\) have mean zero, and will be removed by introducing a new variable \(p_2^{(3)}\). We will then find that \(L p_2^{(3)}\) contains terms of order \(-3\) and \(-4\). To replace the terms of order \(-3\) with their average (which is finally non-zero), we will introduce a function \(p_2^{(4)}\). This will complete the averaging procedure.

We illustrate in Figure 6 the time-dependence of \(p_2, p_2^{(1)}\) and \(p_2^{(2)}\) (slightly shifted for better readability). Clearly, the oscillations of \(p_2^{(1)}\) are much smaller than those of \(p_2\), and we barely perceive the oscillations of \(p_2^{(2)}\), since they are smaller than the random fluctuations.

![Figure 6](image-url)

\textbf{Figure 6} – The effect of the coordinate changes (2.5) and (2.7) on the effective oscillations. Note that two of the curves are shifted vertically for easier readability.

Before we state the result of this averaging process, we introduce a convenient notation for the remainders.

---

2The irregularity of the envelope of \(p_3\) in Figure 6 is due to the randomness of the phases of the two oscillatory forces \(w_1\) and \(w_C\): they sometimes add up, and sometimes compensate each other. Note also that the trajectory of \(p_2^{(2)}\) is rougher than the other two, since the definition of \(p_2^{(2)}\) involves \(p_1\), which is directly affected by the stochastic force.
**Definition 2.1.** Let \( f, g \) be two functions defined on the set \( \{ x \in \Omega : p_2 \neq 0 \} \). We say that \( f \) is \( O_2(g) \) if there is a polynomial \( z \) such that when \( |p_2| \) is large enough,

\[
|f(x)| \leq z(p_1,p_3,p_4)|g(x)|.
\] (2.8)

The analogous notation \( O_3 \) will be used when \( |p_3| \) is large, with a polynomial \( z(p_1,p_2,p_4) \).

This notation reflects the fact that when most of the energy is at site 2 (resp. 3), one can forget about the dependence on \( p_1, p_3, p_4 \) (resp. \( p_1, p_2, p_4 \)), provided that it is at most polynomial (by the compactness of \( T^4 \), the position \( q \) is irrelevant). For example, the term \((p_1 W_L + p_3 W_C)/p_2^2 \) in (2.7) is \( O_2(p_2^{-2}) \).

It is easy to realize that the \( O_j, j = 2, 3 \), follow the same basic rules as the usual \( O \). In particular, 
\[ O_j(g_1) + O_j(g_2) = O_j(|g_1|+|g_2|) \] and \( O_j(g_1)O_j(g_2) = O_j(g_1g_2) \).

**Proposition 2.2.** There are functions \( \tilde{p}_2 \) and \( \tilde{p}_3 \) of the form

\[
\tilde{p}_2 = p_2 + \frac{W_L + W_C}{p_2} + \frac{p_1 W_L + p_3 W_C}{p_2^2} + O_2(p_2^{-3}),
\] (2.9)

\[
\tilde{p}_3 = p_3 + \frac{W_R + W_C}{p_3} + \frac{p_4 W_R + p_2 W_C}{p_3^2} + O_3(p_3^{-3}),
\] (2.10)

such that for \( j = 2, 3 \),

\[
L\tilde{p}_j = -\alpha_j p_j^{-3} + O_j(p_j^{-4}),
\] (2.11)

where \( \alpha_2 > 0, \alpha_3 > 0 \) are defined in (1.13). Furthermore,

\[
\partial_{p_1}\tilde{p}_2 = \frac{W_L}{p_2^2} + O_2(p_2^{-3}), \quad \partial_{p_4}\tilde{p}_2 = O_2(p_2^{-4}),
\]

\[
\partial_{p_1}\tilde{p}_3 = O_3(p_3^{-4}), \quad \partial_{p_4}\tilde{p}_3 = \frac{W_R}{p_3^2} + O_3(p_3^{-3}).
\] (2.12)

**Proof.** It suffices to consider the case \( j = 2 \). The variable \( \tilde{p}_2 \) is constructed as in [5]. We continue the averaging procedure started above. It is easy to check that \( Lp_2^{(2)} \) can be written as

\[
Lp_2^{(2)} = \frac{1}{p_2^2} \partial_{q_2} R_1 + -\frac{2p_1(W_L w_C + W_L w_L) + 2p_3(W_C w_L - W_C w_C)}{p_2^3},
\]

with

\[
R_1 = -p_1^2 W_L - p_3^2 W_C - \gamma_1 p_1 W_L^{[1]} + W_L^2 + W_L W_C + W_C^2 + W_C^{[1]} w_R.
\]

Since it is a total derivative, the term of order \(-2\) has zero \( q_2 \)-average, and by introducing \( p_2^{(3)} = p_2^{(2)} - \frac{R_1}{p_2^2} \), we find

\[
Lp_2^{(3)} = \frac{\partial_{q_2} R_2 + w_L W_L^{[1]} \gamma_1 + p_1(W_C w_L - 2 W_L w_C) + p_3(2 W_C w_L - W_L w_C)}{p_2^3} + O_2(p_2^{-4}),
\] (2.13)

with

\[
R_2 = -p_1^3 W_L - p_3^3 W_C - 3 \gamma_1 p_1^2 W_L^{[1]} - \gamma_1^2 p_1 W_L^{[2]} + 3p_1 W_L^2 + 2 \gamma_1 T_1 W_L^{[1]} + (p_3 - p_4) w_R' W_C^{[2]} + 3 p_3 W_C^2 + 3p_3 W_C^{[1]} w_R.
\]

One can then average the terms of order \(-3\) in (2.13). We have again \( \langle \partial_{q_2} R_2 \rangle_2 = 0 \) by periodicity, and after integration by parts we find

\[
\langle W_C w_L \rangle_2 = \langle w_C W_L \rangle_2 \quad \text{and} \quad \langle \gamma_1 w_L W_L^{[1]} \rangle_2 = -\gamma_1 \langle W_L^2 \rangle_2 = -\alpha_2.
\]
where the second inequality is immediate for sufficiently large $k$, we have on the same set (for the signs, recall that $W_L = W_L(q_2 - q_1)$ and $W_C = W_C(q_3 - q_2)$). By adding appropriate counterterms (not written explicitly), we obtain a function $p_2^{(4)} = p_2^{(3)} + O_2(p_2^{-4})$ such that

$$Lp_2^{(4)} = -\frac{\alpha_2}{p_2^3} + \frac{\langle p_2 W_L u_C - p_1 W_C u_L \rangle_2}{p_2^3} + O_2(p_2^{-4}).$$

The first term in the right-hand side is the one we are looking for, and we deal with the other term of order $-3$ (which is non-zero) as follows. We observe that

$$\langle p_2 W_L u_C - p_1 W_C u_L \rangle_2 = (p_1 \partial_{q_1} + p_2 \partial_{q_2}) \langle W_L u_C \rangle_2 = L \langle W_L u_C \rangle_2,$$

since $\langle W_L u_C \rangle_2$ is a function of $q_1, q_3$ only. We then set

$$\tilde{p}_2 = p_2^{(4)} - \frac{\langle W_L u_C \rangle_2}{p_2^3}$$

and obtain (2.11). It is immediate by the construction of $\tilde{p}_2$ that (2.12) holds. 

We now introduce a useful lemma, which says that remainders of the kind $O_j(|p_j|^{-r})$, $j = 2, 3$, can be made very small on $\Omega_j(k, R)$, provided that the parameters $k, R$ are large enough.

**Lemma 2.3.** Let $j \in \{2, 3\}$ and $r > 0$. Fix $\varepsilon > 0$ and a function $f = O_j(|p_j|^{-r})$. Then, for all sufficiently large $k$ and $R$, we have

$$\sup_{x \in \Omega_j(k, R)} |f(x)| \leq \varepsilon.$$

**Proof.** We prove the result for $f = O_2(|p_2|^{-r})$. By Definition 2.1 and (1.11), there is a polynomial $z$ such that for all large enough $R$ and all $k$, we have $|f| \leq z(p_1, p_3, |p_2|^{-r})$ on $\Omega_2(k, R)$. But then, we have on the same set

$$|f| \leq \frac{z(p_1, p_3, p_4)}{|p_2|^r} \leq \frac{c + c(p_2^2 + p_3^2 + p_4^2)^N}{|p_2|^r} \leq \frac{c + c|p_2|^{2N}}{|p_2|^r} \leq c|p_2|^\frac{2N}{k} - r,$$

where the second inequality is immediate for sufficiently large $N$, the third inequality comes from the definition of $\Omega_2$, and the fourth inequality holds because $|p_2|$ is bounded away from zero on $\Omega_2(k, R)$. Recalling (1.11), we obtain the desired result when $k$ is large enough so that $\frac{2N}{k} - r < -\frac{r}{2}$. 

We now construct partial Lyapunov functions in the regions $\Omega_2$ and $\Omega_3$.

**Proposition 2.4.** Let $0 < \theta < \min(1/T_1, 1/T_4)$ and $a \in (0, 1)$. Consider the functions $3$

$$V_2 = e^{[\tilde{p}_2]_+^a + \frac{a}{2} \tilde{p}_2^2} \left(1 + F_2(q_2 - q_1)/p_2^3 \right),$$

$$V_3 = e^{[\tilde{p}_3]_+^a + \frac{a}{2} \tilde{p}_3^2} \left(1 + F_3(q_3 - q_4)/p_3^3 \right),$$

with the $\tilde{p}_j$ of Proposition 2.2, and with $F_2, F_3 : \mathbb{T} \to \mathbb{R}$ such that $F_2'(s) = \theta^2 \gamma_1 T_1(\langle W_L^2 \rangle - W_L^2(s))$, and $F_3'(s) = \theta^2 \gamma_4 T_4(\langle W_R^2 \rangle - W_R^2(s))$. Then, there are constants $C_1, C_2, C_3 > 0$, independent of $a \in (0, 1)$, such that for all sufficiently large $k$ and $R$, we have for $j = 2, 3$ the following inequalities on $\Omega_j$:

$$C_1 e^{[\tilde{p}_j]_+^a + \frac{a}{2} \tilde{p}_j^2} < V_j < C_2 e^{[\tilde{p}_j]_+^a + \frac{a}{2} \tilde{p}_j^2},$$

$$L V_j \leq -C_3 p_j^{-2} e^{[\tilde{p}_j]_+^a + \frac{a}{2} \tilde{p}_j^2}.$$

$3$ The role of the contribution $|\tilde{p}_j|_+^a$ is to facilitate the patchwork that will lead to a global Lyapunov function in §4. The corrections involving $F_2$ and $F_3$ help average some $W_L^2$ and $W_R^2$ that appear in the computations. Without this correction, we would need a condition on $\theta$ that is more restrictive than the natural condition $\theta < \min(1/T_1, 1/T_4)$. 

13
Proof. By symmetry, it suffices to prove the result for \( j = 2 \). In this proof, we do not allow the \( \mathcal{O}_2 \) to depend on \( a \in (0, 1) \) (that is, we want the bound (2.8) to hold uniformly in \( a \in (0, 1) \)). We start by proving (2.15). For large enough \( R \), we have that \( |p_2| > 2 \) on \( \Omega_2 \). Moreover, since \( \tilde{p}_2 = p_2 + \mathcal{O}_2(p_2^{-1}) \) and \( F_2(q_2 - q_1)/p_2^3 = \mathcal{O}_2(p_2^{-3}) \), we have by Lemma 2.3 that for large enough \( k, R \), it holds on \( \Omega_2 \) that

\[
|\tilde{p}_2| > 1 \quad \text{and} \quad \left| \frac{F_2(q_2 - q_1)}{p_2^3} \right| < \frac{1}{2}. \tag{2.17}
\]

Moreover, since both \( |\tilde{p}_2| \) and \( |p_2| \) are > 1, (2.9) implies, for all \( a \in (0, 1) \),

\[
||p_2|^a - |\tilde{p}_2|^a|| \leq |\tilde{p}_2|^2 - p_2^2 = |2(W_L + W_C) + \mathcal{O}_2(p_2^{-1})|.
\]

Since \( W_L \) and \( W_C \) are bounded, it follows from Lemma 2.3 that we can bound the right-hand side by a constant, so that we find

\[

\text{uniformly in } a. \quad \text{By this, by the definition of } V_2, \quad \text{and by (2.17), we obtain (2.15). We now prove (2.16). Let } f(s) = e^{\|s\|^a + \frac{b}{2}s^2} \quad \text{and note that}
\]

\[
L(e^{\|p_2\|^a + \frac{b}{2}p_2^2}) = Lf(\tilde{p}_2) = f'(\tilde{p}_2)L\tilde{p}_2 + f''(\tilde{p}_2) \sum_{b=1,4} \gamma_b T_b(\partial_b \tilde{p}_2)^2. \tag{2.19}
\]

By Proposition 2.2, we have on \( \Omega_2 \) that

\[
f'(\tilde{p}_2)L\tilde{p}_2 = e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( \frac{\alpha |\tilde{p}_2|^a}{\tilde{p}_2} + \theta \tilde{p}_2 \right) \left( -\alpha_2 p_2^{-3} + \mathcal{O}_2(p_2^{-4}) \right)
\]

\[
= e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( -\alpha_2 \theta p_2^{-2} + \mathcal{O}_2(p_2^{-3}) \right), \tag{2.20}
\]

where we have used that \( \tilde{p}_2 = p_2 + \mathcal{O}_2(p_2^{-1}) \), and that \( a|\tilde{p}_2|^{a-1} < 1 \) (since \( |\tilde{p}_2| > 1 \)), so that on \( \Omega_2 \), the \( \mathcal{O}_2(p_2^{-3}) \) obtained is indeed uniform in \( a \). Next, one can verify that uniformly in \( a \in (0, 1) \) and \( |\tilde{p}_2| > 1 \),

\[
f''(\tilde{p}_2) \leq f(\tilde{p}_2) \left( \theta^2 \tilde{p}_2^{-2} + 2\theta |\tilde{p}_2| + c \right). \]

Moreover, by (2.12) we have \( \sum_{b=1,4} \gamma_b T_b(\partial_b \tilde{p}_2)^2 = \gamma_1 T_1 W_L^2/p_2^2 + \mathcal{O}_2(p_2^{-5}) \), so that on \( \Omega_2 \),

\[
f''(\tilde{p}_2) \sum_{b=1,4} \gamma_b T_b(\partial_b \tilde{p}_2)^2 \leq e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( \theta^2 \tilde{p}_2^{-2} + 2\theta |\tilde{p}_2| + c \right) \left( \gamma_1 T_1 \frac{W_L^2}{p_2^2} + \mathcal{O}_2(p_2^{-5}) \right)
\]

\[
eq e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( \theta^2 \gamma_1 T_1 \frac{W_L^2}{p_2^2} + \mathcal{O}_2(p_2^{-3}) \right). \tag{2.21}
\]

Therefore, by (2.19), (2.20) and (2.21),

\[
L(e^{\|p_2\|^a + \frac{b}{2}p_2^2}) \leq \frac{1}{p_2^2}e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( -\alpha_2 \theta + \theta^2 \gamma_1 T_1 W_L^2 + \mathcal{O}_2(p_2^{-1}) \right). \]

But then

\[
LV_2 = \left( 1 + \frac{F_2(q_2 - q_1)}{p_2^3} \right) L(e^{\|p_2\|^a + \frac{b}{2}p_2^2}) + e^{\|p_2\|^a + \frac{b}{2}p_2^2} L \left( \frac{F_2(q_2 - q_1)}{p_2^3} \right)
\]

\[
\leq \left( 1 + \frac{F_2(q_2 - q_1)}{p_2^3} \right) \frac{1}{p_2^2}e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( -\alpha_2 \theta + \theta^2 \gamma_1 T_1 W_L^2 + \mathcal{O}_2(p_2^{-1}) \right)
\]

\[
+ e^{\|p_2\|^a + \frac{b}{2}p_2^2} \left( \theta^2 \gamma_1 T_1 \left( \frac{W_L^2}{p_2^2} - W_L^2 \right) + \mathcal{O}_2(p_2^{-3}) \right) \]

14
We would like, as above, to add a correction to

\[ \frac{1}{p_2} e^{i \hat{p}_2 n + \frac{4}{p_2} \hat{q}_2} \left( -\alpha_2 \theta + \theta^2 \gamma_1 T_1 \langle W^2 \rangle + O_2(p_2^{-1}) \right). \]

Using the definition (1.14) of \( \alpha_2 \) and the condition on \( \theta \), we find that \( -\alpha_2 \theta + \theta^2 \gamma_1 T_1 \langle W^2 \rangle \) is negative. Using then Lemma 2.3 to make the \( O_2(p_2^{-1}) \) very small, and combining the result with (2.18) completes the proof.

\[ \square \]

3 When both central rotors are fast

We now study the regime where both \( |p_2| \) and \( |p_3| \) are large (not necessarily of the same order of magnitude), and \( |p_1| \) and \( |p_4| \) are much smaller. We then have two fast variables: \( q_2 \) and \( q_3 \). As we will see, this will lead to some trouble related to resonances, and averaging the rapid oscillations will not be enough. We start with some formal computations thinking in terms of powers of \( p_2 \) and \( p_3 \), and then restrict ourselves to the set \( \Omega_c(\ell, m, R) \) for some appropriate parameters.

3.1 Averaging with two fast variables: resonances

Now the fast-slow decomposition is as follows: \( q_1, q_4 \) and \( p \) are the slow variables, and \( q_2, q_3 \) are the fast variables, with the approximate dynamics (for short times)

\[
\begin{align*}
    p(t) & \approx p(0), \\
    q_i(t) & \approx q_i(0), \quad i = 1, 4, \\
    q_2(t) & \approx q_2(0) + p_2(0)t \pmod{2\pi}, \\
    q_3(t) & \approx q_3(0) + p_3(0)t \pmod{2\pi},
\end{align*}
\]

(3.1)

generated by \( L_2 + L_3 = p_2 \partial_{q_2} + p_3 \partial_{q_3} \), which we see as the most important contribution in \( L \). Let again \( f, g : \Omega \to \mathbb{R} \) and assume that

\[ Lf = g. \]

We would like, as above, to add a correction to \( f \) in the left-hand side in order to replace \( g \) with its average in the right-hand side. However, since the fast motion of \( (q_2, q_3) \) on \( \mathbb{T}^2 \) (in the dynamics (3.1)) follows orbits that are open or closed depending on whether \( p_2 \) and \( p_3 \) are commensurable or not, there seems to be no natural notion of “average of \( g \)” that is continuous with respect to the slow variables.

Consider for example \( g(x) = \sin(2q_2 - q_3) \). In our approximation, \( \sin(2q_2(t) - q_3(t)) \) oscillates with frequency \( (2p_2 - p_3)/2\pi \). The average is zero when \( p_3 \neq 2p_2 \), and \( \sin(2q_2(t) - q_3(t)) \) remains constant when \( p_3 = 2p_2 \). When \( p_3 \) is close to \( 2p_2 \), the oscillations are slow, and one cannot simply average \( \sin(2q_2(t) - q_3(t)) \). More generally, any smooth function \( g \) on \( \Omega \) can be written as

\[ \sum_{n,m \in \mathbb{Z}} a_{n,m} \sin(nq_2 + mq_3 + \varphi_{n,m}) \]

for some coefficients \( a_{n,m} \) and \( \varphi_{n,m} \) which depend on the slow variables \( q_1, q_4 \) and \( p \). Each such term gives rise to problems close to the line \( p_3/p_2 = -n/m \) in the \( p_2p_3 \)-plane.

However, if \( g \) depends on \( q_2 \) but not on \( q_3 \), then no problem appears. In the approximation (3.1), the quantity \( g(x(t)) \) then oscillates rapidly around \( \langle g \rangle_2 \), which is then a function of the slow variables \( q_1, q_4 \) and \( p \). Then, as in §2.1, we use \( G = \int (g - \langle g \rangle_2) dq_2 \) (we choose the integration constant independent of \( q_3 \)), so that \( (L_2 + L_3)(G/p_2) = L_2(G/p_2) = g - \langle g \rangle_2 \). Thus, \( L(f - G/p_2) = \langle g \rangle_2 + (L - L_2 - L_3)(f - G/p_2) \), which has the desired form. Similarly, if \( g \) depends on \( q_3 \) but not on \( q_2 \), we use the counterterm \( G/p_3 \) with \( G = \int (g - \langle g \rangle_3) dq_3 \). And of course, if \( g \) can be decomposed as the sum of a function not involving \( q_3 \) and a function not involving \( q_2 \), then we can average each part separately and sum the two counterterms.

It turns out that we will mostly encounter terms that depend only on one of the fast variables, and are therefore easy to average. We will go as far as possible averaging such terms, and then introduce a method to deal with the resonant terms (involving both \( q_2 \) and \( q_3 \)) that appear.
3.2 Application to the central energy

As a starting point, we use the central energy

\[ H_c = \frac{p_2^2}{2} + \frac{p_3^2}{2} + W_L + W_C + W_R. \]

**Definition 3.1.** Let \( A_s \equiv \{ x \in \Omega \, : \, p_2 \neq 0, p_3 \neq 0 \} \) and let \( f, g \) be two functions defined on a set \( A \subset A_s \). We say that \( f \) is \( O_c(g) \) (on the set \( A \)) if there is a polynomial \( z \) such that for all \( x \in A \) with \( \min(|p_2|, |p_3|) \) large enough, we have

\[ |f(x)| \leq z(p_1, p_4)|g(x)|. \]

Unless explicitly stated otherwise, we take \( A = A_s \).

We state the main result of this section.

**Proposition 3.2.** There is a function of the form

\[ \tilde{H}_c = H_c + \frac{p_1 W_L}{p_2} + \frac{p_2 W_R}{p_3} + O_c(|p_2|^{-2} + |p_3|^{-2}), \tag{3.2} \]

such that

\[ LH_c = -\frac{\alpha_2}{p_2^2} - \frac{\alpha_3}{p_3^2} + O_c(|p_2|^{-3/2} + |p_3|^{-5/2}), \tag{3.3} \]

with \( \alpha_j \) as defined in (1.14). Furthermore,

\[ \partial_{p_1} \tilde{H}_c = \frac{W_L}{p_2} + O_c(p_2^{-2}), \quad \partial_{p_3} \tilde{H}_c = \frac{W_R}{p_3} + O_c(p_3^{-2}). \tag{3.4} \]

In order to reduce the length of some symmetric formulae, we use the notation “\( + \iff \)” as a shorthand for the other half of the terms with the indices exchanged as follows: \( 1 \iff 4, 2 \iff 3, L \iff R \), and the sign of \( W_C \) changed (due to the asymmetry of the argument \( q_3 - q_2 \) of \( W_C \)).

In order to prepare the proof of Proposition 3.2, we proceed as follows. We first see that

\[ L(H_c) = -p_1 W_L - p_4 W_R. \]

Since \( W_L \) does not involve \( q_3 \) and \( W_R \) does not involve \( q_2 \), it easy to find appropriate counterterms: we introduce

\[ H_c^{(1)} = H_c + \frac{p_1 W_L}{p_2} + \frac{p_2 W_R}{p_3}, \tag{3.5} \]

and obtain

\[ LH_c^{(1)} = \frac{-\gamma_1 p_1 W_L - p_1^2 W_L + p_1 W_L(w_L - w_C)}{p_2} + \frac{p_1 W_L(w_L - w_C)}{p_2^2} + \iff. \]

The terms of order \( 1/p_2 \) do not depend on \( q_3 \) and have mean zero with respect to \( q_2 \) (again \( w_L W_L = \partial_{q_2} W_L^2/2 \) has zero \( q_2 \)-average by periodicity). Similarly, the terms in \( 1/p_3 \) depend only on \( q_3 \) and average to zero. Therefore, we introduce a next round of counterterms:

\[ H_c^{(2)} = H_c^{(1)} + \left( \frac{\gamma_1 p_1 W_L^1}{p_2^2} + \frac{p_1^2 W_L - W_L^2}{p_2^2} + \iff \right), \]

and obtain

\[ LH_c^{(2)} = \left( \frac{-p_1^3 W_L - 3\gamma_1 p_1^2 W_L - \gamma_1^2 p_1 W_L^1 + 4p_1 W_L w_L + 2\gamma_1 T_1 W_L}{p_2^2} + \iff \right) \]

\[ + \frac{\gamma_1 W_L W_L^1}{p_2^2} + \frac{\gamma_4 w_R W_R^1}{p_3^2} - \frac{p_1 W_L w_C}{p_2} + \frac{p_4 W_R w_C}{p_3} + O_c(|p_2|^{-3} + |p_3|^{-3}). \tag{3.6} \]
The terms in the first line are easy to eliminate, since each one depends on only one of the fast variables and averages to zero. The terms \( \gamma_1 w L W_{S}^{|1|}/p_2^2 \) and \( \gamma_4 w R W_{S}^{|1|}/p_2^3 \) are the ones we are looking for, since after integrating by parts, we find \( \langle \gamma_1 w L W_{S}^{|1|} \rangle_2 = -\gamma_1 \langle W_{S}^{|2|} \rangle_2 = -\alpha_2 \) and \( \langle \gamma_4 w R W_{S}^{|1|} \rangle_3 = -\gamma_4 \langle W_{R}^{|2|} \rangle_3 = -\alpha_3 \). The two terms involving \( W_{I} w C \) and \( W_{R} w C \) are more problematic and we leave them untouched for now. By introducing the appropriate counterterms (which we do not write explicitly), we obtain a function \( H_c^{(3)} = H_c^{(2)} + O_c(|p_2|^{-3} + |p_3|^{-3}) \) such that

\[
LH_c^{(3)} = -\frac{\alpha_2}{p_2^2} - \frac{\alpha_3}{p_3^2} - \frac{p_1 W_{I} w C}{p_2^2} + \frac{p_4 W_{R} w C}{p_3^3} + O_c(|p_2|^{-3} + |p_3|^{-3}).
\]  

(3.7)

In order to obtain (3.3), we must get rid of the two “mixed” terms involving \( W_{I} w C \) and \( W_{R} w C \), which are of the same order as the dissipative contributions involving \( \alpha_2 \) and \( \alpha_3 \). Since they each depend on both \( q_2 \) and \( q_3 \), these terms are not easy to get rid of, due to the resonance phenomenon discussed above. In fact, as discussed in Appendix A, these resonances have a physical meaning. Their effect becomes clearly visible when \( T_1 = T_4 = 0 \) (which is not covered by our assumptions): they alter the dynamics in the \( p_2 \rangle p_3 \)-plane, but do not prevent \( H_c \) from decreasing in average. We postpone to §3.3 the construction of the counterterms that will eliminate these resonant terms.

We introduce next two technical lemmata and an application of Proposition 3.2. The following lemma is analogous to Lemma 2.3.

**Lemma 3.3.** Let \( j \in \{2, 3\} \) and \( r > 0 \). Fix an integer \( \ell > 0 \), and an \( \varepsilon > 0 \). Let \( f \) be some \( O_c(|p_j|^{-r}) \) on the set \( A_\varepsilon = \{ x \in \Omega : p_2 \neq 0, p_3 \neq 0 \} \). Then, for all sufficiently large \( m \) and \( R \), we have

\[
\sup_{x \in \Omega_c(\ell, m, R)} |f(x)| < \varepsilon.
\]

**Proof.** We prove the result for \( f = O_c(|p_2|^{-r}) \) and proceed as in Lemma 2.3. By Definition 3.1 and (1.12), there is a polynomial \( z \) such that for all \( m \) and all sufficiently large \( R \), we have on \( \Omega_c(\ell, m, R) \),

\[
|f| \leq \frac{\varepsilon(p_1, p_2)}{|p_2|^r} \leq \frac{c + c(p_1^2 + p_2^2)^N}{|p_2|^r} \leq \frac{c + c(p_2 + p_3)^2}{|p_2|^r} \leq \frac{c + (p_2 + p_3)^2}{|p_2|^r} \leq \frac{c + |p_2|^{2N}}{|p_2|^r} \leq \frac{2N}{m - r},
\]

where we choose \( N \) large enough and use the definition of \( \Omega_c \). By (1.12), we conclude that the desired result holds for \( m \) large enough so that \( \frac{2N}{m - r} < -\frac{r}{2} \).

**Lemma 3.4.** Let \( f = O_c(|p_2^j p_3^k|) \) for some \( z_1, z_2 \in \mathbb{R} \) such that \( z_1, z_2 \) have the same sign. Then, \( f = O_c(|p_2|^{z_1} + |p_3|^{z_2}) \).

**Proof.** We apply Young’s inequality in the form \( xy \leq x^a + y^b \) with \( a = \frac{z_1 + z_2}{z_1} > 0, b = \frac{z_1 + z_2}{z_2} > 0 \), and \( x = |p_2|^{z_1}, y = |p_3|^{z_2} \). We obtain \( |p_2|^{z_1} |p_3|^{z_2} \leq |p_2|^{z_1 + z_2} + |p_3|^{z_1 + z_2} \). This, and the definition of \( O_c \), complete the proof.

As a consequence of Proposition 3.2 we have:

**Proposition 3.5.** Let \( 0 < \theta < \min(1/T_1, 1/T_4) \) and define

\[
V_c = \tilde{H}_c e^{\theta \tilde{H}_c} \left( 1 + \frac{F_2(q_2 - q_1)}{p_2^2} + \frac{F_3(q_3 - q_4)}{p_3^3} \right),
\]

with the \( \tilde{H}_c \) of Proposition 3.2 and \( F_2, F_3 \) as in Proposition 2.4. Let \( \ell > 1 \) be a fixed integer. Then, there are constants \( C_4, C_5, C_6 > 0 \) such that for all large enough \( m \) and \( R \), the following inequalities hold on \( \Omega_c(\ell, m, R) \):

\[
C_4(p_2^2 + p_3^2)e^{\frac{3}{2}(p_2^2 + p_3^2)} < V_c < C_5(p_2^2 + p_3^2)e^{\frac{3}{2}(p_2^2 + p_3^2)},
\]

(3.8)

\[
LV_c < C_6 e^{\frac{3}{2}(p_2^2 + p_3^2)}.
\]

(3.9)
Proof. We first prove (3.8). By (3.2), the boundedness of the potentials, and Lemma 3.3, we have for $m, R$ large enough that on $\Omega_c$, 
\[ \left| \tilde{H}_c - \frac{p_2^2}{2} - \frac{p_3^2}{2} \right| < 2 \quad \text{and} \quad \left| \frac{F_2(q_2 - q_1)}{p_2^2} + \frac{F_3(q_3 - q_4)}{p_3^3} \right| < \frac{1}{2}. \]  
(3.10)

In addition, if $m, R$ are large enough, $p_2^2 + p_3^2$ is large on $\Omega_c$, so that the first part of (3.10) implies that $c(p_2^2 + p_3^2) < \tilde{H}_c < c(p_2^2 + p_3^2)$. This and (3.10) imply (3.8).

We next prove (3.9). Define $f(s) = se^{\theta s}$. By Proposition 3.2,
\[ L(\tilde{H}_c e^{\theta \tilde{H}_c}) = f'(\tilde{H}_c) L\tilde{H}_c + f''(\tilde{H}_c) \sum_{b=1,4} \gamma_b T_b (\partial_{p_b} \tilde{H}_c)^2 \]
\[ = e^{\theta \tilde{H}_c} \left( \theta \tilde{H}_c + 1 \right) \left( -\frac{\alpha_2}{p_2^2} + \frac{\alpha_3}{p_3^3} + O_c(|p_2|^{-5/2} + |p_3|^{-5/2}) \right) \]
\[ + e^{\theta \tilde{H}_c} \left( \theta^2 \tilde{H}_c + 2\theta \right) \left( \gamma_1 T_1 \frac{W_{L}^2}{p_2^2} + \gamma_4 T_4 \frac{W_{R}^2}{p_3^3} + O_c(|p_2|^{-3} + |p_3|^{-3}) \right). \]
(3.11)

Now observe that for any $C \in \mathbb{R}$, we have
\[ \tilde{H}_c + C = \frac{p_2^2 + p_3^2}{2} + O_c(1) = \frac{p_2^2 + p_3^2}{2} \left( 1 + O_c(p_2^{-2} + p_3^{-2}) \right), \]

since trivially $(p_2^2 + p_3^2)^{-1} \leq p_2^{-2} + p_3^{-2}$. But then, by (3.11) and Lemma 3.4, we find that
\[ L(\tilde{H}_c e^{\theta \tilde{H}_c}) \leq e^{\theta \tilde{H}_c} \frac{p_2^2 + p_3^2}{2} \left( \frac{\theta^2 \gamma_1 T_1 W_{L}^2}{p_2^2} - \theta \alpha_2 + O_c(|p_2|^{-1/2}) \right) + O_c, \]

where we have used that $O_c(|p_2|^{-5/2} + |p_3|^{-5/2}) \leq O_c(|p_2|^{-5/2}) + O_c(|p_3|^{-5/2})$. As in the proof of Proposition 2.4, the corrections involving $F_2$ and $F_3$ replace the oscillatory terms $W_{L}^2$ and $W_{R}^2$ with their averages:
\[ LV_c = L \left( \tilde{H}_c e^{\theta \tilde{H}_c} \right) \left( 1 + \frac{F_2}{p_2^2} + \frac{F_3}{p_3^3} \right) + \tilde{H}_c e^{\theta \tilde{H}_c} L \left( \frac{F_2}{p_2^2} + \frac{F_3}{p_3^3} \right) \]
\[ \leq e^{\theta \tilde{H}_c} \frac{p_2^2 + p_3^2}{2} \left( \frac{\theta^2 \gamma_1 T_1 \langle W_{L}^2 \rangle}{p_2^2} - \theta \alpha_2 + O_c(|p_2|^{-1/2}) \right) + O_c, \]

where $\langle W_{L}^2 \rangle$ is the average of the $W_{L}^2$ terms. Therefore, by the definition (1.14) of $\alpha_j$ and the condition on $\theta$, we have
\[ LV_c \leq e^{\theta \tilde{H}_c} \frac{p_2^2 + p_3^2}{2} \left( -c + O_c(|p_2|^{-1/2}) \right) \frac{1}{p_2^2} + \frac{c + O_c(|p_3|^{-1/2})}{p_3^3} \]

Finally, by Lemma 3.3, and using that $(p_2^2 + p_3^2)(p_2^{-2} + p_3^{-2}) > 2$, we indeed obtain (3.9). \hfill \Box

We now return to the proof of Proposition 3.2. We need to find some counterterms to eliminate the mixed terms in (3.7). For this, we use a subdivision of $A_* = \{ x \in \Omega : p_2 \neq 0, p_3 \neq 0 \}$ into 3 disjoint pieces, as shown in Figure 7:

\[ A_1 = \{ x \in A_* : |p_2 + p_3| \geq (p_2 - p_3)^2 \}, \]
\[ A_2 = \{ x \in A_* : (p_2 - p_3)^2 > |p_2 + p_3| > (p_2 - p_3)^2/2 \}, \]
\[ A_3 = \{ x \in A_* : (p_2 - p_3)^2 \geq 2|p_2 + p_3| \}. \]

By construction, $A_1$ is close to the diagonal $p_2 = p_3$, $A_3$ is far from it, and $A_2$ is some transition region.

By the proof of Proposition 3.2, we have
\[ \left| \tilde{H}_c - \left( \frac{p_2^2}{2} + \frac{p_3^2}{2} \right) \right| < 2 \quad \text{and} \quad \left| \frac{F_2(q_2 - q_1)}{p_2^2} + \frac{F_3(q_3 - q_4)}{p_3^3} \right| < \frac{1}{2}. \]
(3.10)
Lemma 3.6. The following holds:

(i) On $A_1 \cup A_2$, the quantity $|p_2 - p_3|$ is both $O_c(\sqrt{|p_2|})$ and $O_c(\sqrt{|p_3|})$.

(ii) On $A_2 \cup A_3$, the quantity $|p_2 - p_3|^{-1}$ is both $O_c(|p_2|^{-1/2})$ and $O_c(|p_3|^{-1/2})$.

Proof. Trivially, (i) holds because on $A_1 \cup A_2$, we have the scaling $|p_1 - p_2| \lesssim \sqrt{|p_2 + p_1|} \sim \sqrt{|p_2|} \sim \sqrt{|p_1|}$. To obtain (ii), observe that either $p_2$ and $p_3$ have the same sign and by the definition of $A_2 \cup A_3$, $|p_2 - p_3| \gtrsim \sqrt{|p_2 + p_3|} = \sqrt{|p_2| + |p_3|} \geq \max(\sqrt{|p_2|}, \sqrt{|p_3|})$, or they have a different sign and $|p_2 - p_3| = |p_2| + |p_3| \geq \max(|p_2|, |p_3|) \gtrsim \max(\sqrt{|p_2|}, \sqrt{|p_3|})$. In both cases, we have the desired bound.

We first work on $A_1 \cup A_2$. In this region, $p_2$ and $p_3$ are close to each other, and are both large in absolute value. It is then easy to find a counterterm for $p_1 W_L w_C / p_2^2$ and $p_4 W_R w_C / p_3^2$. Indeed, $W_L$ and $W_R$ oscillate very rapidly (the respective frequencies are approximately $p_2/2\pi$ and $p_3/2\pi$), while $w_C$ oscillates only “moderately”, with frequency $(p_3 - p_2)/2\pi$. One can then simply average the rapidly oscillating part, and obtain

**Lemma 3.7.** Let $R_{12} = p_1 W_L^{[1]} w_C / p_2^3 - p_4 W_R^{[1]} w_C / p_3^3$. Then,

$$LR_{12} = \frac{p_1 W_L w_C}{p_2^2} - \frac{p_4 W_R w_C}{p_3^2} + O_c(|p_2|^{-5/2} + |p_3|^{-5/2}) \quad (on \ A_1 \cup A_2).$$

Proof. We have for the first term:

$$L \frac{p_1 W_L^{[1]} w_C}{p_2^3} = \frac{p_1 W_L w_C}{p_2^2} + \frac{p_1 W_L^{[1]} w_C \cdot (p_4 - p_2)}{p_3^2} + O_c(p_2^{-3}) = \frac{p_1 W_L w_C}{p_2^2} + O_c(|p_2|^{-5/2}),$$

where the last equality uses Lemma 3.6 (i). A similar computation for the second terms completes the proof.

The counterterm $R_{12}$ works well on $A_1 \cup A_2$ because $|p_3 - p_2|$ is small compared to $p_2$ and $p_3$. We now have to find a counterterm $R_{23}$ that works on $A_2 \cup A_3$ and then patch the two counterterms together on $A_2$. We state the properties of the counterterm $R_{23}$ in the following lemma, but postpone its construction to §3.3.
We set now
\[ R_{23} = \frac{p_1 W_L w_C}{p_2^2} - \frac{p_4 W_R w_C}{p_3^2} + O_c(|p_2|^{-5/2} + |p_3|^{-5/2}) \quad (\text{on } A_2 \cup A_3) \] (3.13)
and
\[ \partial_{p_1} R_{23} = O_c(p_2^{-2}) \quad \text{and} \quad \partial_{p_4} R_{23} = O_c(p_3^{-2}). \] (3.14)

Assuming that Lemma 3.8 is proved, we next join the two counterterms \( R_{12} \) and \( R_{23} \) by a smooth interpolation on \( A_2 \) in order to prove Proposition 3.2.

**Proof of Proposition 3.2.** We introduce a smooth function \( \rho : \mathbb{R} \cup \{-\infty, \infty\} \to [0, 1] \) such that \( \rho(x) = 1 \) when \( |x| \leq 1 \) and \( \rho(x) = 0 \) when \( |x| \geq 2 \). We then consider the function
\[ \rho \left( \frac{(p_3 - p_2)^2}{p_2 + p_3} \right), \] (3.15)
which is well-defined and smooth on the set \( A_* = A_1 \cup A_2 \cup A_3 = \{ x \in \Omega : p_2 \neq 0, p_3 \neq 0 \} \). Moreover, it is equal to 1 on \( A_1 \), and 0 on \( A_3 \). We now omit the arguments and simply write \( \rho \) instead of (3.15). Using Lemma 3.7 and Lemma 3.8, we obtain
\[ L (\rho R_{12} + (1 - \rho) R_{23}) = \rho L R_{12} + (1 - \rho) L R_{23} + (R_{12} - R_{23}) L \rho \]
\[ = \frac{p_1 W_L w_C}{p_2^2} - \frac{p_4 W_R w_C}{p_3^2} + O_c(|p_2|^{-5/2} + |p_3|^{-5/2}) + (R_{12} - R_{23}) L \rho. \] (3.16)
Observe next that
\[ L \rho = \rho' \left( 2 \frac{(p_3 - p_2)}{p_2 + p_3} (w_L - w_R - 2 w_C) + \frac{(p_3 - p_2)^2}{(p_2 + p_3)^2} (w_L + w_R) \right). \] (3.17)
Since \( \rho' \) has support in \( A_2 \), where \( |p_3 - p_2| \sim |p_2 + p_3|^1/2 \sim |p_2|^{1/2} \sim |p_3|^{1/2}, \) we see that \( L \rho \) is simultaneously \( O_c(|p_2 + p_3|^{-1/2}) \), \( O_c(|p_2|^{-1/2}) \) and \( O_c(|p_3|^{-1/2}) \). But then, by (3.16) and using that \( R_{12} - R_{23} = O_c(|p_2|^{-2} + |p_3|^{-2}) \), we find
\[ L (\rho R_{12} + (1 - \rho) R_{23}) = \frac{p_1 W_L w_C}{p_2^2} - \frac{p_4 W_R w_C}{p_3^2} + O_c(|p_2|^{-5/2} + |p_3|^{-5/2}). \] (3.18)
We set now
\[ \tilde{H}_e = H^{(3)}_e + \rho R_{12} + (1 - \rho) R_{23}. \]
From (3.18) and (3.7), we deduce immediately that (3.3) holds. Moreover, (3.4) follows from (3.14), the expressions for \( H^{(3)}_e \) and \( R_{12} \), and the fact that \( \rho \) does not depend on \( p_1 \) and \( p_4 \). This completes the proof of Proposition 3.2.

### 3.3 Fully decoupled dynamics approximation

We construct here the counterterm \( R_{23} \) of Lemma 3.8, which eliminates the two resonant terms \(-p_1 W_L w_C/p_2^2\) and \(p_4 W_R w_C/p_3^2\) on \( A_2 \cup A_3 \) when both \( |p_2| \) and \( |p_3| \) are large. In this regime, all three interaction forces \( w_L, w_C, w_R \) oscillate rapidly (since \( |p_2|, |p_3 - p_2|\) and \( |p_3| \) are all large) and we expect the dynamics to be well approximated by the following **decoupled dynamics**, where all the interaction forces are removed.

**Definition 3.9.** We call decoupled dynamics the SDE
\[ \begin{align*}
dq_i &= p_i \, dt, & i = 1, \ldots, 4, \\
dp_b &= -\gamma_b p_b \, dt + \sqrt{2\gamma_b \mathcal{I}_b} dB^b_t, & b = 1, 4, \\
dp_j &= 0 \, dt, & j = 2, 3,
\end{align*} \] (3.19)
with generator
\[
\bar{L} = \sum_{i=1}^{4} p_i \partial_{p_i} + \sum_{b=1,4} (-\gamma_b p_b \partial_{p_b} + \gamma_b T_b \partial_{p_b}^2),
\]
and denote by \( \bar{E}_x \) the corresponding expectation value with initial condition \( x \in \Omega \).

We will construct two functions \( U_1, U_4 \) such that \( \bar{L} U_1 = p_1 W_L w_C \) and \( \bar{L} U_4 = -p_4 W_R w_C \). Then, we will introduce a change of variable \( x \mapsto \bar{x}(x) \) such that \( \bar{x} \) approximately obeys the decoupled dynamics, so that \( L(U_1(\bar{x})) \approx p_1 W_L w_C \) and \( L(U_4(\bar{x})) \approx -p_4 W_R w_C \) in the regime of interest. Finally, we will show that the choice \( \bar{R}_{23}(x) = U_4(\bar{x})/p_4^2 + U_4(\bar{x})/p_4^2 \) satisfies the conclusions of Lemma 3.8.

The decoupled dynamics can be integrated explicitly for any initial condition \( x = (q_1, \ldots, q_4) \in \Omega \).

For the outer rotors \( b = 1, 4 \), we have
\[
p_b(t) = e^{-\gamma t} p_b + \sqrt{2 \gamma_b T_b} \int_0^t e^{-(t-s)\gamma_b} dB^b_s,
\]
\[
q_b(t) = q_b + \frac{1 - e^{-\gamma t}}{\gamma_b} p_b + \sqrt{2 \gamma_b T_b} \int_0^t \left( \int_0^s e^{-(s-s')\gamma_b} dB^b_{s'} \right) ds,
\]
and for the central ones \((j = 2, 3)\) we simply have
\[
p_j(t) = p_j, \quad q_j(t) = q_j + p_j t \mod 2\pi,
\]
which is deterministic. We decompose the variables between the central and external rotors as
\[
x = (x_c, x_e) \quad \text{with} \quad x_e = (q_1, p_1, q_4, p_4) \quad \text{and} \quad x_c = (q_2, p_2, q_3, p_3).
\]

Under the decoupled dynamics, the two processes \( x_e(t) \) and \( x_c(t) \) are independent and \( x_e(t) \) is deterministic. Moreover, under the decoupled dynamics, \( x_e(t) \) has the generator
\[
\bar{L}_e = \sum_{b=1,4} (p_b \partial_{p_b} - \gamma_b p_b \partial_{p_b} + \gamma_b T_b \partial_{p_b}^2),
\]
and admits the invariant probability measure \( \bar{\pi}_e \) on \((T \times \mathbb{R})^2\) given by
\[
d\bar{\pi}_e(x_e) = \frac{1}{Z} e^{-\frac{v_1^2}{2\sigma_1^2} - \frac{v_2^2}{2\sigma_2^2}} \, dp_1 \, dp_4 \, dq_1 \, dq_4,
\]
where \( Z \) is a normalization constant (recall that \( T_1, T_4 > 0 \) by assumption).

**Definition 3.10.** We denote by \( S \) the set of functions \( f \in C^\infty(\Omega, \mathbb{R}) \) for which the norm
\[
\|f\| = \sup_{x \in \Omega} \frac{|f(x)|}{1 + p_1^2 + p_4^2}
\]
is finite. We denote by \( S_0 \) the subspace of functions \( f \in S \) for which
\[
\int_{(T \times \mathbb{R})^2} f(x_e, x_c) \, d\bar{\pi}_e(x_c) = 0 \quad \text{for all} \quad x_c \in (T \times \mathbb{R})^2.
\]

We will later consider \( f = p_1 W_L w_C \) and \( f = -p_4 W_R w_C \), which are manifestly in \( S_0 \).

**Lemma 3.11.** There are constants \( C_*, c_* > 0 \) such that for all \( f \in S_0 \), all \( x \in \Omega \), and all \( t \geq 0 \),
\[
|\bar{E}_x f(x(t))| \leq C_* e^{-c_*t} \|f\| \, (1 + p_1^2 + p_4^2).
\]
Proof. As mentioned, $x_e(t)$ and $x_c(t)$ are independent under the decoupled dynamics. Introducing the expectation value $\tilde{E}_x$ with respect to the process $x_e(t)$ under the decoupled dynamics, we obtain that for any function $f$ on $\Omega$,
\[
\tilde{E}_x f(x(t)) = \tilde{E}_x^e f(x_e(t), x_c(t)) ,
\]
where $x_c(t)$ is (deterministically) given by (3.22).

The process $x_e(t)$ under the decoupled dynamics is exponentially ergodic, with the unique invariant measure $\pi_e$ defined above. Indeed, one can check explicitly that this measure is invariant, and introducing the Lyapunov function $V_e(x_e) = 1 + p_1^2 + p_2^2$, we easily obtain that $\tilde{L}_e V_e \leq c - c V_e$. It follows from [20, Theorem 6.1]\(^4\) that there are two constants $C_*, c_* > 0$ such that for any function $g : (\mathbb{T} \times \mathbb{R})^2 \to \mathbb{R}$ such that $g/\tilde{V}_e$ is bounded,
\[
\sup_{x_e} \frac{|\tilde{E}_x^e g(x_e(t)) - \pi_e(g)|}{1 + p_1^2 + p_2^2} \leq C_* e^{-c_*t} \sup_{x_e} \frac{|g(x_e) - \pi_e(g)|}{1 + p_1^2 + p_2^2} .
\]
(3.26)

Let now $f \in S_0$. For any fixed $v \in (\mathbb{T} \times \mathbb{R})^2$, we apply (3.26) to the function $g_v(x_e) = f(x_e, v)$. Since $f \in S_0$, we have $\pi_e(g_v) = 0$. Therefore, for any $t \geq 0$,
\[
\sup_{x_e} \frac{|\tilde{E}_x^e f(x_e(t), v)|}{1 + p_1^2 + p_2^4} \leq C_* e^{-c_*t} \sup_{x_e} \frac{|f(x_e, v)|}{1 + p_1^2 + p_2^4} \leq C_* e^{-c_*t} \|f\| .
\]
(3.27)

This holds for all $v$, and in particular for $v = x_e(t)$. Therefore, by (3.25), we have the desired result. \(\square\)

The next proposition constructs a right inverse to $\tilde{L}$ on $S_0$. We use here the notation
\[
x = (x_1, \ldots, x_8) = (q_1, \ldots, q_4, p_1, \ldots, p_4) .
\]
(3.28)

Proposition 3.12. Let $f \in S_0$ be a function such that for all multi-indices $\alpha$, we have $\partial^\alpha f \in S_0$, and let
\[
(\tilde{K} f)(x) = - \int_0^\infty \tilde{E}_x f(x(t)) \, dt .
\]
(3.29)

Then

(i) $\tilde{K} f$ and its derivatives of all orders are in $S$.

(ii) The operator $\tilde{K}$ is a right inverse of $\tilde{L}$ (on $S_0$):
\[
\tilde{L} \tilde{K} f = f .
\]

Proof. By Lemma 3.11, the integral (3.29) converges absolutely for all $x$ and we have $\tilde{K} f \in S$. We now prove the result about the derivatives. By (3.21) and (3.22), we can write
\[
\frac{\partial x_i(t)}{\partial x_j} = h_{ij}(t) ,
\]
where the $h_{ij}$ are deterministic functions of $t$ only that grow at most linearly (namely $0, 1, e^{-\gamma t}$, $(1 - e^{-\gamma t})/\gamma_0$, and $t$). This is a consequence of the affine nature of the decoupled solutions (3.21) and (3.22). We then have
\[
\frac{\partial}{\partial x_j} (\tilde{E}_x f(x(t))) = \sum_{i=1}^8 h_{ij}(t) \tilde{E}_x [(\partial_i f)(x(t))] .
\]

\(^4\)One should also check that there is a skeleton with respect to which every compact set is petite. This is obvious, but can be proved with methods similar to those of §5 in [5].
Assume that for all \( j \) we have by Lemma 3.11 that
\[
\sum_{i_1, \ldots, i_n} \left( \prod_{k=1}^n h_{i_k,j_k}(t) \right) \mathbb{E}_x[ \partial_{i_1, \ldots, i_n} f](x(t)) ,
\]
where the sum is taken over all \((i_1, \ldots, i_n) \in \{1, 2, \ldots, 8\}^n\). Since by assumption \( \partial_{i_1, \ldots, i_n} f \in \mathcal{S}_0 \), we have by Lemma 3.14 that \( |\mathbb{E}_x[ \partial_{i_1, \ldots, i_n} f](x(t))| \leq c e^{-ct} (1 + p_1^2 + p_4^2) \). But then, by (3.30), we have
\[
|\partial_{i_1, \ldots, i_n} \bar{K} f(x)| = \left| \int_0^\infty \partial_{i_1, \ldots, i_n} (\mathbb{E}_x f(x(t))) \, dt \right|
\leq c \left( 1 + p_1^2 + p_4^2 \right) \sum_{i_1, \ldots, i_n} \left| \int_0^\infty \left( \prod_{k=1}^n h_{i_k,j_k}(t) \right) e^{-ct} \, dt \right| .
\]
Since the \( h_{ij} \) grow at most linearly, the time-integrals in the right-hand side converge. Therefore, \( \bar{K} f \) is \( C^\infty \) and (i) holds.

For the second statement, we observe that
\[
\bar{L} \bar{K} f = -\int_0^\infty \mathbb{E}_x f(x(t)) \, dt = -\int_0^\infty \frac{d}{dt} \mathbb{E}_x f(x(t)) \, dt = \mathbb{E}_x f(x(0)) = f(x) ,
\]
where we have used that \( \lim_{t \to \infty} \mathbb{E}_x f(x(t)) = 0 \) by (3.27).

**Remark 3.13.** We believe that this result (or some modification of it) is true under more general assumptions. The proof presented here fails to work if we add pinning potentials, since then the decoupled dynamics cannot be solved explicitly. Also, adding a constant force to either end of the chain (as is allowed in [5]) would lead to a different invariant measure \( \bar{\pi}_a \) for the external rotors (in the presence of both an external force and some pinning, the expression of \( \bar{\pi}_a \) is not known explicitly [12]). These difficulties explain why, contrary to [5], we do not allow for the presence of pinning potentials and constant forces at the ends of the chain.

We now have an inverse of \( \bar{L} \) on a given class of functions. We next use it to find an approximate inverse of \( L \). The key is to introduce a change of variables \( \bar{x} = (\bar{q}_1, p_1, \ldots, \bar{q}_4, \bar{p}_4) \) such that for nice enough functions \( f \), it holds that \( L(f(\bar{x})) \approx (\bar{L} f)(\bar{x}) \) in the regime of interest. Here and in the sequel, it is always understood that \( \bar{x} \) is viewed as a function of \( x \). We compare the actions of \( L \) and \( \bar{L} \) in Lemma 3.14. We state this lemma with the notation (3.28), and write generically
\[
L = \sum_i \left( f_i(x) \partial_t + \sigma_i \partial_t^2 \right) \quad \text{and} \quad \bar{L} = \sum_i \left( \bar{f}_i(x) \partial_t + \sigma_i \partial_t^2 \right) .
\]
In our case, only \( \sigma_5 \) and \( \sigma_8 \), which correspond to the variables \( p_1 \) and \( p_4 \), are non-zero.

**Lemma 3.14.** Consider a change of coordinates \( x \mapsto \bar{x}(x) = x + s(x) \), defined on some set \( \Omega_0 \subset \Omega \). Assume that for all \( j \),
\[
L(\bar{x}_j) = \bar{f}_j(\bar{x}) + \varepsilon_j(x)
\]
for some \( \varepsilon_j \). Then, for any smooth function \( h \), we have for all \( x \in \Omega_0 \) that
\[
L(h(\bar{x})) = (\bar{L} h)(\bar{x}) + \zeta(x) ,
\]
where
\[
\zeta(x) = \sum_j (\partial_j h)(\bar{x}) \varepsilon_j(x) + 2 \sum_{i,j} \sigma_i (\partial_{i,j} h)(\bar{x}) \partial_t s_i(x) + \sum_{i,j,k} \sigma_i (\partial_{i,j,k} h)(\bar{x}) \partial_t s_j \partial_t s_k .
\]

\( \square \)
Proof. We do the computation for the case of just one variable \( x \in \mathbb{R} \). Let \( g(x) = \bar{x}(x) = x + s(x) \).
From the definition of \( L \) and \( \bar{L} \), and since by assumption \( Lg = \bar{f} \circ g + \varepsilon \), we find
\[
L(h \circ g) = (h' \circ g) \cdot Lg + \sigma \cdot (h'' \circ g) \cdot g^2
= (h' \circ g) \cdot (\bar{f} \circ g + \varepsilon) + \sigma \cdot (h'' \circ g) \cdot g^2
= (\bar{L}h) \circ g + (h' \circ g) \cdot \varepsilon + \sigma \cdot (h'' \circ g) \cdot (g^2 - 1)
= (\bar{L}h) \circ g + (h' \circ g) \cdot \varepsilon + \sigma \cdot (h'' \circ g) \cdot (2s^2 + s^2).
\]
The desired result follows from generalizing to the multivariate case. \( \square \)

We consider now the following change of variables defined on \( A_2 \cup A_3 \):
\[
\bar{q}_1 = q_1, \quad \bar{p}_1 = p_1 - \frac{W_L(q_2 - q_1)}{p_2} = p_1 + O_c(p_2^{-1}),
\]
\[
\bar{q}_2 = q_2, \quad \bar{p}_2 = p_2 + \frac{W_L(q_2 - q_1)}{p_2} - \frac{W_C(q_3 - q_2)}{p_3 - p_2} = p_2 + O_c(|p_2|^{-1/2}),
\]
with analogous expressions for the indices 3, 4. Here, we have used Lemma 3.6 (ii) to replace \( W_L/(p_3 - p_2) \) with \( O_c(|p_2|^{-1/2}) \). Straightforward computations show that, on \( A_2 \cup A_3 \),
\[
L(\bar{q}_1) = -\gamma_1 p_1 + O_c(p_2^{-1}) = -\gamma_1 \bar{p}_1 + O_c(p_2^{-1}),
\]
\[
L(\bar{q}_2) = O_c(|p_2|^{-1} + (p_2 - p_3)^{-2}) = O_c(p_2^{-1}),
\]
\[
L(\bar{p}_2) = p_2 + O_c(|p_2|^{-1/2}),
\]
with similar expressions for the indices 3, 4 (we have again used Lemma 3.6 (ii)).

While one could choose a more refined change of variables by going to higher orders, the change (3.33) is good enough for our purpose.

Lemma 3.15. Let \( f \in S \). Then \( f \) is \( O_c(1) \). Moreover, given any function \( \xi : \Omega \to [0, 1] \), we have that \( f(x + \xi(x)(\bar{x} - x)) = O_c(1) \) on \( A_2 \cup A_3 \). In particular, \( f(\bar{x}) = O_c(1) \) on \( A_2 \cup A_3 \).

Proof. By assumption, \( |f(x)| \leq \|f\|(1 + p_1^2 + p_2^2) \) on \( \Omega \), so that immediately \( f = O_c(1) \). Moreover, \( f(x + \xi(x)(\bar{x} - x)) \) is well-defined on \( A_2 \cup A_3 \), and
\[
\left| f(x + \xi(x)(\bar{x} - x)) \right| \leq \|f\| \left( 1 + \left( p_1 - \xi(x) \frac{W_L}{p_2} \right)^2 + \left( p_4 - \xi(x) \frac{W_R}{p_3} \right)^2 \right),
\]
which is indeed a \( O_c(1) \) on this set. The claim about \( f(\bar{x}) \) follows from the choice \( \xi \equiv 1 \). \( \square \)

Proposition 3.16. Let \( f \) satisfy the assumptions of Proposition 3.12, and consider the change of coordinates (3.33). Let \( h = \bar{K} f \). Then, on the set \( A_2 \cup A_3 \) (meaning that we take \( x \in A_2 \cup A_3 \), and not necessarily \( \bar{x} \in A_2 \cup A_3 \)), we have \( h(\bar{x}) = O_c(1) \) and
\[
L(h(\bar{x})) = f(x) + \mathcal{O}_c(|p_2|^{-1/2} + |p_3|^{-1/2}).
\]

Proof. We use again the notations \( x = (x_1, \ldots, x_8) = (q_1, \ldots, q_4, p_1, \ldots, p_4) \) and (3.31). We apply Lemma 3.14 with the coordinate change \( \bar{x} = x + s(x) \) defined by (3.33). Then, the \( s_j \) are given by (3.33), and the \( \varepsilon_j \) are given by (3.34). Observe then that on \( A_2 \cup A_3 \), all the \( s_j \) and \( \varepsilon_j \) are at most \( O_c(|p_2|^{-1/2}) \) or \( \mathcal{O}_c(|p_3|^{-1/2}) \). The only non-zero \( \sigma_i \) are \( \sigma_5 = \gamma_1 T_1 \) and \( \sigma_8 = \gamma_4 T_4 \). Moreover, \( \partial_{x_5} s_j = \partial_{p_1} s_j = 0 \) for all \( j \in \{1, 2, \ldots, 8\} \), and similarly \( \partial_{x_8} s_j = \partial_{p_4} s_j = 0 \). Therefore, from
(3.32) we are left with $\zeta(x) = \sum_j (\partial_j h)(\bar{x})\varepsilon_j(x)$. We now apply this to the function $h = \bar{K}f$. By Proposition 3.12, we have $Lh = f$, so that

$$L(h(\bar{x})) = f(\bar{x}) + \sum_j (\partial_j h)(\bar{x})\varepsilon_j(x). \quad (3.35)$$

To obtain the desired results, it remains to make the following two observations. First, by the mean value theorem, there is for each $x$ some $\xi(x) \in [0, 1]$ such that on $A_2 \cup A_3$, 

$$f(\bar{x}) - f(x) = \sum_j s_j(x)(\partial_j f)(x + \xi(x)s(x)) = \mathcal{O}_c(|p_2|^{-1/2} + |p_3|^{-1/2}), \quad (3.36)$$

where we have applied Lemma 3.15 to $\partial_j f$, which is in $S$ by assumption. Secondly, using Lemma 3.15 and the fact that $\partial_j h \in S$ by Proposition 3.12, we find

$$\sum_j (\partial_j h)(\bar{x})\varepsilon_j(x) = \mathcal{O}_c(|p_2|^{-1/2} + |p_3|^{-1/2}),$$

which, together with (3.35) and (3.36), completes the proof. \qed

We are now ready for the

**Proof of Lemma 3.8.** Let

$$U_1(q_1, \ldots, q_3, p_1, \ldots, p_3) = \bar{K}(p_1 W_L(q_2 - q_1)w_C(q_3 - q_2)),$$

$$U_4(q_2, \ldots, q_4, p_2, \ldots, p_4) = \bar{K}(-p_4 W_R(q_3 - q_4)w_C(q_3 - q_2)),$$

and

$$R_{23}(x) = \frac{U_1(\bar{x})}{p_2^2} + \frac{U_4(\bar{x})}{p_3^2}.$$

That $U_1$ depends only on $(q_1, \ldots, q_3, p_1, \ldots, p_3)$ follows from the independence of the four rotors under the decoupled dynamics. Similarly for $U_4$. It is easy to check that $f = p_1 W_L w_C$ satisfies the assumptions of Proposition 3.12: Since $\langle f \rangle_1 = 0$, we also have $\langle \partial^2 f \rangle_1 = 0$ for each multi-index $\alpha$. From this it follows that $\bar{\pi}_c(f) = 0$ and that $\bar{\pi}_c(\partial f) = 0$, since $\bar{\pi}_c$ is uniform with respect to $q_1$. Since no powers of $p_1$ or $p_4$ appear upon differentiation, we indeed obtain that $f$ and all its derivatives are in $S_0$. A similar argument applies to $f = -p_4 W_R w_C$. Therefore, applying Proposition 3.16, we find that on the set $A_2 \cup A_3$, the functions $U_1(\bar{x})$ and $U_4(\bar{x})$ are $\mathcal{O}_c(1)$, and that

$$L(U_1(\bar{x})) = p_1 W_L w_C + \mathcal{O}_c(|p_2|^{-1/2} + |p_3|^{-1/2}),$$

$$L(U_4(\bar{x})) = -p_4 W_R w_C + \mathcal{O}_c(|p_2|^{-1/2} + |p_3|^{-1/2}). \quad (3.37)$$

In (3.37), the arguments of $W_L$, $W_R$ and $W_C$ are indeed $x$ and not $\bar{x}$. Finally, we have

$$LR_{23} = \frac{L(U_1(\bar{x}))}{p_2^2} + \frac{L(U_4(\bar{x}))}{p_3^2} + \mathcal{O}_c(p_2^{-3}) + \mathcal{O}_c(p_3^{-3}). \quad (3.38)$$

The assertion (3.13) then follows from this, (3.37), and Lemma 3.4. The assertion (3.14) follows from the definition of $R_{23}$ and the following observation: using the explicit expression for $\bar{x}$, Proposition 3.12 (i) and Lemma 3.15, we find $\partial_{p_1}(U_1(\bar{x})) = (\partial_{p_1} U_1)(\bar{x}) = \mathcal{O}_c(1)$, and $\partial_{p_4}(U_1(\bar{x})) = (\partial_{p_4} U_1)(\bar{x}) = 0$ (and similarly for $U_4$). \qed

**Remark 3.17.** The construction above relies on the strict positivity of the temperatures. Nonetheless, it can be adapted to the case $T_1 = T_4 = 0$. In this case, the external rotors are not ergodic under the decoupled dynamics: they deterministically slow down and asymptotically reach a given position that depends on the initial condition. Therefore, the conclusion of Lemma 3.11 does not hold. However, the
Then, there is a smooth function $\psi$ we constructed here the Lyapunov function of Theorem 1.4. We start by fixing the parameters defining which will be crucial. As a consequence, \(x(t)\) is the deterministic solution given in (3.21) and (3.22) with initial condition \(x\) and \(T_1 = T_4 = 0\). Since \(p_1(t)\) decreases exponentially fast and \(W_Lw_c\) is bounded, this integral still converges. A similar argument applies to \(U_4\).

4 Constructing a global Lyapunov function

We construct here the Lyapunov function of Theorem 1.4. We start by fixing the parameters defining the sets \(\Omega_2, \Omega_3, \Omega_c\) and the functions \(V_2, V_3, V_c\).

We assume throughout this section that \(\theta\) is fixed and satisfies

\[
0 < \theta < \min\left(\frac{1}{T_1}, \frac{1}{T_4}\right). \tag{4.1}
\]

This condition is necessary to apply Proposition 2.4 and Proposition 3.5. In addition, it guarantees that when \(p_1^2 + p_2^2\) is large, \(\exp(\theta H)\) decreases very fast:

**Lemma 4.1.** There are constants \(C_7, C_8 > 0\) such that

\[
Le^{\theta H} \leq (C_7 - C_8(p_1^2 + p_2^2))e^{\theta H}.
\]

**Proof.** Since \(Le^{\theta H} = \sum_{b=1,4} (-\gamma_b(1-\theta T_b)p_b^2 + \gamma_b(1-\theta T_b)e^{\theta H}\), the result follows from the condition on \(\theta\). \(\square\)

We next choose the constants \(k, \ell, a, m\), and finally \(R\). First, we fix \(k\) large enough, and require a lower bound \(R_0\) on \(R\) so that the conclusions of Proposition 2.4 hold on \(\Omega_j(k, R), j = 2, 3\). We then fix the parameters \(a\) (appearing in \(V_2, V_3\)) and \(\ell\) such that

\[
\frac{2}{\ell} < a < \frac{2}{k}. \tag{4.2}
\]

As a consequence, \(\Omega_c(\ell, m, R)\) now depends only on \(m \) and \(R\), which we fix large enough so that Proposition 3.5 applies, and so that \(m > \ell\) and \(R \geq R_0\).

This choice satisfies the condition \(1 \leq k < \ell < m\) imposed in (1.8). This ensures that the sets \(\Omega_j (j = 2, 3)\) and \(\Omega_c\) have “large” intersections, and that they indeed look as shown in Figure 4 and Figure 5. Moreover, condition (4.2) ensures that for large \(|p_j|, j = 2, 3,\)

\[
|p_j|^{2/\ell} \ll |p_j|^a \ll |p_j|^{2/k},
\]

which will be crucial.

We next introduce smooth cutoff functions for the sets \(\Omega_2, \Omega_3, \Omega_c\). For this, we consider for each set a thin “boundary layer” included in the set itself.

**Definition 4.2.** Let \(X \subset \Omega\). We define \(B(X) = \{x \in X : \text{dist}(x, X^c) > 1\}\).

**Lemma 4.3.** Consider a set \(P \subset \mathbb{R}^4\), viewed as a subset of momentum space and let \(X = T^4 \times P \subset \Omega\). Then, there is a smooth function \(\psi : \mathbb{R}^4 \to [0, 1]\) with the following properties. First, \(\psi(p) = 1\) on \(X \setminus B(X)\) and \(\psi(p) = 0\) on \(X^c\), with some interpolation on \(B(X)\). Secondly, \(\partial^\alpha \psi\) is bounded on \(\mathbb{R}^4\) for each multi-index \(\alpha\).
We prove these bounds one by one.

The sets $Ω_2, Ω_3$ and $Ω_c$ are the product of $T^4$ and a set $P \subset \mathbb{R}^4$, so that Lemma 4.3 applies. We denote by $ψ_2, ψ_3$, and $ψ_c$ the cutoff functions obtained.

Proof of Theorem 1.4. We show that the Lyapunov function

$$V = 1 + e^{θH} + \sum_{j=2,3} ψ_j(p) V_j + Mψ_c(p) V_c$$

has the necessary properties, provided that the constant $M$ is large enough. We start by proving (1.5).

From (2.15) and (3.8), we immediately obtain the bound

$$1 + e^{θH} \leq V \leq c(ψ_2 e^{∥ψ∥} + ψ_3 e^{∥ψ∥} + ψ_c \cdot (p_2^2 + p_3^2)) e^{θH}, \quad (4.3)$$

which is slightly sharper than (1.5). We next turn to the bound on $LV$. We introduce the set

$$G = \{ x \in Ω : p_1^2 + p_4^2 < (1 + C_7)/C_8 \} \quad , \quad (4.4)$$

with $C_7, C_8$ as in Lemma 4.4, so that

$$Le^{θH} \leq -e^{θH} + (1 + C_7) e^{θH} \leq -e^{θH} + C_6 \quad (4.5)$$

for some $C_6 > 0$, where we have used that $H ≤ c + p_2^2 + p_3^2$ on $G$. Moreover, observe that for $j = 2, 3$, there is a polynomial $z_j(p)$ such that

$$L(ψ_j V_j) = ψ_j LV_j + V_j Lψ_j + 2 \sum_{b=1,4} γ_b T_b(∂_p ψ_j)(∂_p V_j)$$

$$≤ -C_3 p_j^2 e^{∥ψ∥^2 + 2p_2^2} + V_j Lψ_j + 2 \sum_{b=1,4} γ_b T_b(∂_p ψ_j)(∂_p V_j) \quad (4.6)$$

where the first inequality follows from (2.16) and the second inequality holds because the derivatives of $ψ_j(p)$ have support on $B(Ω_j)$, because $|ψ_j - 1_{Ω_j}| ≤ 1_{B(Ω_j)}$, and because of (2.15). Similarly, using Proposition 3.5, we obtain a polynomial $z_c(p)$ such that on $Ω$

$$L(ψ_c(p) V_c) \leq -1_{Ω_c} C_6 + 1_{B(Ω_c)} z_c(p) e^{θH} \quad (4.7)$$

Combining (4.5), (4.6) and (4.7), we find

$$LV \leq -e^{θH} - \sum_{j=2,3} 1_{Ω_j} C_3 p_j^2 e^{∥ψ∥^2 + 2p_2^2} - 1_{Ω_c} M C_6 e^{θH} \quad (4.8)$$

The first line contains the “good” terms. We next show that the terms in the second line are dominated by the good ones. Let $ε > 0$. We claim that there is a (large) compact set $K$ (which depends on $ε$) such that

$$1_{B(Ω_j)} z_j(p) e^{∥ψ∥^2 + 2p_2^2} ≤ εe^{θH} + c1_K, \quad j = 2, 3 \quad , \quad (4.9)$$

$$1_{B(Ω_c)} z_c(p) e^{θH} + ε \sum_{j=2,3} 1_{Ω_j} p_j^{-2} e^{∥ψ∥^2 + 2p_2^2} + c1_K \quad , \quad (4.10)$$

$$1_{G} e^{θH} \leq 1_{Ω_c} e^{θH} + ε \sum_{j=2,3} 1_{Ω_j} p_j^{-2} e^{∥ψ∥^2 + 2p_2^2} + c1_K \quad . \quad (4.11)$$

We prove these bounds one by one.
• \textbf{Proof of (4.9).} We prove the bound for \( j = 2 \). First observe that
\[
|z_2(p) e^{\frac{\|p\|^2}{2} - \theta H}| < c z_2(p) e^{\|p\|^2 - \frac{\theta}{2} (p_2^4 + p_3^4)}.
\]
By the definition of \( \Omega_2 \), when \( \|p\| \to \infty \) in \( B(\Omega_2) \), we find \( p_1^2 + p_3^2 + p_4^2 \sim \|p_2\|^{2/k} \gg \|p_2\|^a \) (recalling that \( 2/k > a \)). Thus, the right-hand side of (4.12) vanishes in this limit, since \( z_2 \) is only a polynomial. This implies (4.9) if \( K \) is large enough.

• \textbf{Proof of (4.10).} By inspection of the definition (1.10) of \( \Omega_c \), there are three regions \( B(\Omega_c)_i \), \( i = 1, 2, 3 \), such that if the compact set \( K \) is large enough,
\[
B(\Omega_c) \subset K \cup B(\Omega_c)_1 \cup B(\Omega_c)_2 \cup B(\Omega_c)_3,
\]
where \( B(\Omega_c)_1 \) is such that \( p_2^2 + p_3^2 \sim (p_1^2 + p_4^2)^m \), where \( B(\Omega_c)_2 \subset \Omega_2 \) is such that \( p_3^2 \sim p_2^2 \), and where \( B(\Omega_c)_3 \subset \Omega_3 \) is such that \( p_2^2 \sim p_3^2 \) (see Figure 4 and Figure 5).

Since \( z_c(p) e^{\frac{\theta}{2} (p_2^2 + p_3^2)} \) is bounded on compact sets, (4.10) trivially holds on \( K \). We next turn to \( B(\Omega_c)_1 \). We have
\[
z_c(p) e^{\frac{\theta}{2} (p_2^2 + p_3^2)} - \theta H < c z_c(p) e^{\frac{\theta}{2} (p_2^2 + p_3^2)}.
\]
The right-hand side vanishes when \( \|p\| \to \infty \) in \( B(\Omega_c)_1 \), and thus by enlarging \( K \) if necessary, we find \( z_c(p) e^{\frac{\theta}{2} (p_2^2 + p_3^2)} \leq c e^{\theta H} + c1_K \) on \( B(\Omega_c)_1 \), which implies (4.10).

Now, consider \( B(\Omega_c)_2 \). We have
\[
z_c(p) e^{\frac{\theta}{2} (p_2^2 + p_3^2)} p_2^{-2} e^{\|p_2\|^2} = z_c(p) p_2^{-2} e^{\frac{\theta}{2} (p_2^2 - \|p_2\|^2)}.
\]
As \( \|p\| \to \infty \) in \( B(\Omega_c)_2 \), the right-hand side vanishes, since \( p_3^2 \sim \|p_2\|^{2/\ell} \) and \( a > 2/\ell \). Therefore, \( z_c(p) e^{\frac{\theta}{2} (p_2^2 + p_3^2)} \leq c e^{\frac{\theta}{2} (p_2^2 - \|p_2\|^2)} + c1_K \) on \( B(\Omega_c)_2 \) for large enough \( K \), and thus (4.10) holds on \( B(\Omega_c)_2 \) since \( B(\Omega_c)_2 \subset \Omega_2 \).

A similar argument applies for \( B(\Omega_c)_3 \), which completes the proof of (4.10).

• \textbf{Proof of (4.11).} Observe that for \( K \) large enough, the set \( G \) defined in (4.4) verifies
\[
G \subset K \cup \Omega_2 \cup \Omega_c \cup \Omega_3.
\]
On \( \Omega_c \), (4.11) holds trivially. On \( G \cap \Omega_2 \setminus \Omega_c \), and for large enough \( \|p\| \), we have \( p_3^2 \leq \|p_2\|^{2/\ell} \) (otherwise we would have \( x \in \Omega_c \)), and therefore
\[
e^{\frac{\theta}{2} (p_2^2 + p_3^2)} p_2^{-2} e^{\|p_2\|^2} = p_2^{-2} e^{\|p_2\|^2} \leq p_2^{-2} e^{\frac{\theta}{2} (p_2^2 - \|p_2\|^2)}.
\]
Since \( a > 2/\ell \), we have, by enlarging \( K \) if necessary, that \( c e^{\frac{\theta}{2} (p_2^2 + p_3^2)} \leq c e^{\frac{\theta}{2} (p_2^2 - \|p_2\|^2)} + c1_K \) on \( G \cap \Omega_2 \setminus \Omega_c \), so that (4.11) holds on this set. Since a similar argument applies in \( G \cap \Omega_3 \setminus \Omega_c \), the proof of (4.11) is complete.

Substituting (4.9), (4.10), and (4.11) into (4.8), we find
\[
LV \leq -(1 - 2\varepsilon - M\varepsilon) e^{\theta H} - \sum_{j=2,3} \Omega_j (C_3 - C_9\varepsilon - M\varepsilon) p_j^{-2} e^{\|p_j\|^2 + \frac{\theta}{2} p_j^2}
\]
\[
- \Omega_c (MC_6 - C_9) e^{\frac{\theta}{2} (p_2^2 + p_3^2)} + c1_K.
\]
Since the constants $C_i$ do not depend on $\varepsilon$ and $M$, we can make the three parentheses $(1 - 2\varepsilon - M\varepsilon)$, $(C_3 - C_1\varepsilon - M\varepsilon)$ and $(MC_0 - C_3)$ positive by choosing $M$ large enough and then $\varepsilon$ small enough. Using again (2.15) and (3.8), we finally obtain

$$LV \leq -ce^{tH} - c\sum_{j=2,3} 1_{\Omega_j} \frac{V_j}{p_j^2} - c1_{\Omega_e} \frac{V_e}{p_e^2 + p_3^2} + c1_K .$$

(4.13)

We now show that this implies (1.6). Observe that since $V$ which, by the definition (1.7) of $\varphi$ (in the language of 7): Douc-Fort-Guillin (2009)

This is a combination of [7, Theorems 3.2 and 3.4] for the following “inverse Young’s functions”

**Proof.**

(i) follows from Hörmander’s condition. The proof that Hörmander’s condition holds, which relies on Assumption 1.2, is very similar to that of Lemma 5.3 of [5] and is left to the reader. The proof of (ii) is exactly as in Lemma 5.6 of [5], and (iii) follows from (i), (ii), and Proposition 6.2.8 of [19].

We can now finally give the

5 Proof of Theorem 1.3

Now that we have a Lyapunov function (Theorem 1.4), we can prove Theorem 1.3 in the spirit of [5]. In addition to Theorem 1.4, we need a few other ingredients.

We first use the result of [7] about subgeometric ergodicity. We state it here in a simplified form. For a definition of “irreducible skeleton” and “petite set”, see the introduction of [7] or [5, Section 2].

**Theorem 5.1** (Douc-Fort-Guillin (2009)). Assume that a skeleton of the process (1.2) is irreducible and let $V : \Omega \to [1, \infty)$ be a smooth function such that $\lim_{\|p\| \to \infty} V(q, p) = +\infty$. If there are a petite set $K$ and a constant $C$ such that $LV \leq C1_K - \varphi(V)$ for some differentiable, concave and increasing function $\varphi : [1, \infty) \to (0, \infty)$, then the process admits a unique invariant measure $\pi$, and for any $z \in [0, 1]$, there exists a constant $C'$ such that for all $t \geq 0$ and all $x \in \Omega$,

$$\|P^t(x, \cdot) - \pi\|_{(\varphi \circ \pi)'} \leq g(t)C'V(x),$$

(5.1)

where $g(t) = (\varphi \circ H_\varphi^{-1}(t))^{-1}$, with $H_\varphi(u) = \int_1^u \frac{ds}{\varphi(s)}$.

**Proof.** This is a combination of [7, Theorems 3.2 and 3.4] for the following “inverse Young’s functions” (in the language of [7]): $\Psi_1(s) \propto s^{-1}$ and $\Psi_2(s) \propto s^2$.

Theorem 1.4 provides most of the input to Theorem 5.1, but we still need to check that there is an irreducible skeleton, and that the set $K$ of Theorem 1.4 is petite. To this end, we introduce, as in [5],

**Proposition 5.2.** The following holds.

(i) The transition probabilities $P^t(x, dy)$ have a $C^\infty([0, \infty) \times \Omega \times \Omega)$ density $p_t(x, y)$ and the process is strong Feller.

(ii) The time-1 skeleton chain $(x_n)_{n=0,\ldots}$ admits the Lebesgue measure on $(\Omega, \mathcal{B})$ as a maximal irreducibility measure.

(iii) All compact subsets of $\Omega$ are petite.

**Proof.** (i) follows from Hörmander’s condition. The proof that Hörmander’s condition holds, which relies on Assumption 1.2, is very similar to that of Lemma 5.3 of [5] and is left to the reader. The proof of (ii) is exactly as in Lemma 5.6 of [5], and (iii) follows from (i), (ii), and Proposition 6.2.8 of [19].

We can now finally give the
Proof of Theorem 1.3. Let $0 \leq \theta_1 < \min(1/T_1, 1/T_2)$ and $\theta_2 > \theta_1$. Choose now $\theta \in (\theta_1, \theta_2)$ such that $\theta < \min(1/T_1, 1/T_2)$. By Theorem 1.4, we have a Lyapunov function $1 + e^{\theta H} \leq V \leq e^{(e^{p_1 n} + e^{p_2 n})e^{\theta H}}$ with $\alpha \in (0, 1)$ such that $LV \leq cLK - \psi(V)$, where $\psi(s) = c_3 s/(2 + \log(s))$, and where $K$ is a compact (and therefore petite) set. Let now $z \in (0, 1)$ be such that $z\theta > \theta_1$. By Theorem 5.1, we obtain the existence of a unique invariant measure $\pi$ such that

$$\|P^t(x, \cdot) - \pi\|_{(\varphi \circ V)^z} \leq ce^{-\lambda t/2}V(x),$$

where we have used that with the notation of Theorem 5.1,

$$g(t) = (\varphi \circ H^{-1}(t))z^{-1} \leq ce^{-\lambda t/2}$$

for some $\lambda > 0$. Indeed, it is straightforward that $H_\varphi(u) = \frac{1}{c_3} \int_1^u \frac{2 + \log s}{s} ds = \frac{1}{c_3} (\log u)^2 + \frac{2}{c_3} \log u$, so that $H^{-1}(t) = \exp((2c_3 t + 4)^{1/2} - 2)$ and $(\varphi \circ H^{-1}(t)) = (2c_3 t + 4)^{-1/2} \exp((2c_3 t + 4)^{1/2} - 2) \geq ce^{t/2}$, which implies (5.3).

Then, (1.4) follows from (5.2) and the following two observations. First, we have $V \leq ce^{\theta_2 H}$ since $\theta < \theta_2$. Secondly, by our choice of $z$, we have $e^{\theta_1 H} \leq c(\varphi \circ V)^z$, so that $\|P^t(x, \cdot) - \pi\|_{(\varphi \circ V)^z} \leq c \|P^t(x, \cdot) - \pi\|_{(\varphi \circ V)^z}$.

Thus, we have proved (iii). Since (i) and the smoothness assertion in (ii) follow from Proposition 5.2, the proof is complete. 

A Resonances in the deterministic case

In §2, two resonant terms appeared, namely $p_1 W_L w_C/p_2^2$ and $-p_4 W_R w_C/p_3^2$. These terms have a physical meaning. We start with the case where $W_1(s) = -\cos(s), I = L, C, R$. Then,

$$W_L w_C = -\cos(q_2 - q_1) \sin(q_3 - q_2) = \frac{\sin(q_1 - q_3)}{2} + \frac{\sin(2q_2 - q_3 - q_1)}{2}.$$  

(A.1)

Consider now the regime where most of the energy is concentrated at sites 2 and 3. In the approximate dynamics (3.1), we see that $\sin(q_1 - q_3)$ oscillates with frequency $p_3/2\pi$ and mean zero, while $\sin(2q_2 - q_3 - q_1)$ oscillates with frequency $(2p_2 - p_3)/2\pi$. When $p_3 = 2p_2$, the second term does not oscillate.

In Figure 8, we represent some trajectories projected onto the $p_2p_3$-plane in the deterministic case (i.e., $T_1 = T_4 = 0$). We observe that some trajectories are “trapped” by the line $p_3/p_2 = 2$, while some others just cross it. By symmetry, the same happens when $p_3/p_2 = 1/2$ because of the term $-p_4 W_R w_C/p_3^2$. This phenomenon does not occur when the same conditions are used with positive temperatures (see Figure 3). A finer analysis (not detailed here) shows that in the resonant regime $p_3/p_2 = 2$, a net momentum flux from $p_3$ to $p_2$ appears, and similarly for $p_3/p_2 = 1/2$ with a flux from $p_2$ to $p_3$. These fluxes stabilize the resonant regimes.

If we take $W_1(s) = -\cos(n_1 s)$ for some $n_1 \in \mathbb{Z}, I = L, C, R$, we find by a decomposition similar to (A.1) some resonances at

$$\frac{p_3}{p_2} \in \left\{ \frac{n_C + n_L}{n_C}, \frac{n_C - n_L}{n_C}, \frac{n_C}{n_C + n_R}, \frac{n_C}{n_C - n_R} \right\}.$$  

(If some of these values are 0 or $\infty$, we exclude them since our approximation is reasonable when both $|p_2|$ and $|p_3|$ are very large.) For example, if we choose $(n_L, n_C, n_R) = (3, 1, 3)$, we obtain the ratios $p_3/p_2 = 4, 1/4, -2, -1/2$, which we indeed observe in Figure 9.

Of course, a similar analysis applies to more general interaction potentials by taking their Fourier series and treating the (products of) modes separately.
Figure 8 – Projection of a few orbits on the $p_2p_3$-plane, with $W_L = W_C = W_R = -\cos$, $\gamma_1 = \gamma_4 = 1$, $T_1 = T_4 = 0$. The resonances are depicted as dashed lines.

Figure 9 – Projection of a few orbits on the $p_2p_3$-plane, with $\gamma_1 = \gamma_4 = 1$, $T_1 = T_4 = 0$, and $(n_L, n_C, n_R) = (3, 1, 3)$. The resonances are depicted as dashed lines.
