Abstract. Insulin receptor substrate-1 (IRS-1) is reported to play a critical role in the development, progression, invasion and metastasis of several types of tumors and is abnormally expressed in nasopharyngeal carcinoma (NPC). Although IRS-1 is predicted to be targeted by microRNA (miR)-144, the biological roles and potential mechanisms of miR-144 in NPC remain unclear. In the present study, the expression levels of miR-144 and IRS-1 in several NPC cell lines were first examined, and found that they were negatively correlated. Following the introduction of the miR-144 mimic, IRS-1 was downregulated at the protein level without affecting the mRNA level. The Cell Counting Kit-8 assay showed that the miR-144 mimic and siRNA targeting IRS-1 mRNA significantly decreased cell proliferation by arresting the cell cycle at the G1/G0 phase. The malignant behaviours of NPC cell lines, including migration, invasion and tumour formation in soft agar, were then analyzed after regulating miR-144 levels; as expected, the results showed that both the miR-144 mimic and siIRS-1 decreased these malignant behaviours. Furthermore, the downregulation of IRS-1 by miR-144 decreased the expression level of dishevelled 2 (Dvl2) protein without affecting its mRNA level, and Dvl2 overexpression abolished the inhibitory effect of the miR-144 mimic in NPC, indicating that miR-144 potentially regulates NPC by indirectly regulating Dvl2. Taken together, the present study results suggest that miR-144 acts as a tumour suppressor in NPC cell lines by regulating IRS-1 and Dvl2, which indicates that it is a potential therapeutic target for NPC treatment.

Introduction

Nasopharyngeal carcinoma (NPC) is a head and neck malignant tumour derived from nasopharyngeal epithelium and has a high incidence rate, with >20 cases per 100,000 individuals in southern China (1). Several factors contribute to NPC occurrence and development, including Epstein-Barr virus (EBV) infection, chemical carcinogens, genetic variation and spontaneous mutation (2). NPC is characterized by metastases via both lymph and blood vessels at the early stage of the disease (3), and subsequently induces the development of distant metastases to the bone, lung and liver, which are major causes of treatment failure after different treatments (4). Although much effort has been devoted, the mechanisms that regulate NPC malignant behaviours, including proliferation, migration, invasion and colony formation, remain poorly understood.

Small non-coding microRNAs (miRNAs/miRs) are a group of small, non-coding RNA molecules that play critical roles in regulating tumorigenesis processes. Moreover, accumulating evidence has demonstrated that abnormalities in the expression profiles of miRNAs are a hallmark of tumorigenesis and development (5). By acting as tumour promoters or inhibitors, miRNAs tightly regulate the occurrence, development and progression of cancer (6). miR-144 is an miRNA identified as a tumour regulator in several types of cancer, including lung cancer, nasopharyngeal carcinoma, hepatocellular carcinoma and clear cell renal cell carcinoma (7-10). However, miR-144 has been reported to act as either an oncogene or tumour suppressor in different types of cells, which has raised an interesting study topic on its regulatory role in NPCs.

Insulin receptor substrate (IRS) proteins are a group of signalling intermediates downstream of cytoplasmic molecules that play critical roles in several diseases, including cancer (11). One member of IRS, termed insulin receptor substrate-1 (IRS-1), was reported to be associated with tumour initiation and progression. IRS-1, activated by insulin/insulin-like growth factor I receptors, induces the transduction of intracellular cascades, including activating PI3K-AKT and Ras-MAPK pathways (12). As IRS-1 regulates several basal processes, including inhibiting autophagy and decreasing oxidative stress-induced apoptosis, the
overexpression of IRS-1 promotes malignant behaviours in several cancer cells (13,14). A study reported that IRS-1 is downregulated by miR-145 and leads to the inhibition of proliferation in colon cancer cells (15). Wu et al (16) reported that, in laryngeal squamous cell carcinoma, miR-144 suppresses the growth and metastasis by targeting IRS1, indicating that miRNAs, including miR-144, may regulate malignant behaviours in cancer by regulating IRS-1.

Dishevelled (Dvl2) is a cytoplasm-nucleus shuttling protein and thus tightly regulates Wnt signalling (17), which is regulated by a variety of factors, including ubiquitin-proteasome and autophagy-lysosomal pathways (18,19). Zhang et al (18) reported that Dvl2 is bound by GABARAPL1, a member of the ATG8 family, and results in degradation through autophagy. Further research also revealed that IRS-1 interacts directly with Dvl2, and overexpression of IRS-1 increased the protein level of Dvl2 by inhibiting ubiquitination and subsequent degradation (20). Subsequently, Dvl2 stabilized by IRS-1 promotes Wnt/β-catenin signalling and thus promotes epithelial-mesenchymal transition (EMT) and cell proliferation in response to Wnt stimulation (20). These results indicate that miRNAs may regulate Dvl2 signalling by post-transcriptional regulation of IRS-1 and modifying physiological processes.

The present study focused on the biological functions and underlying molecular mechanisms of miR-144 via its regulation of IRS-1 and subsequent regulation of malignant behaviors of NPCs.

Materials and methods

Cell culture. Nasopharyngeal carcinoma cell lines NPC-TW01 and SUNE1 were bought from The Cell Bank of Type Culture Collection of The Chinese Academy of Sciences. All cells were maintained in RPMI-1640 medium (Thermo Fisher Scientific, Inc.) supplemented with 10% fetal bovine serum (FBS; Thermo Fisher Scientific, Inc.) and 1% penicillin-streptomycin in a humidified atmosphere containing 5% CO₂ at 37°C. Cells were passaged every three days.

Reverse transcription-quantitative (RT-q)PCR. Total RNA was isolated using TRIzol® according to manufacturer's instruction and was reverse transcribed into complementary DNA using Bio-Rad iScript cDNA Synthesis System (Bio-Rad Laboratories, Inc.) at 42°C for 60 min and denatured at 80°C for 10 min. SYBR-Green PCR Master mix (Thermo Fisher Scientific, Inc.) was employed for qPCR according to manufacturer's instruction. The primers used were as follows: IRS-1 forward, 5’-CAAGATGACCAAGCTCACCAGTTCTGTA-3’; IRS-1 reverse, 5’-AGA GTGATTCCACCTCCTC-3’; Dvl2 forward, 5’-GGCTATCCA GGTGCCCTCCTC-3’; Dvl2 reverse, 5’-AGAGCGGTGCAACC ACATTC-3’; β-actin forward, 5’-CATGTTACGTGTGCTATCCA GGC-3’; and β-actin reverse, 5’-CTCTGTTAATGTCAGGCAC GAT-3’. For quantitative detection of miRNAs, total RNA was revere transcribed using All-in-One™ miRNA qRT-PCR Detection System (Guangzhou RiboBio Co., Ltd.) following the manufacturer's instructions. Primer for miR-144 (cat. no. HmiRQP09010) and RNU6-2 (cat. no. HmiRQP09001) were bought from Guangzhou RiboBio Co., Ltd. Relative quantification of mRNA and miRNA expression were calculated by using the 2−ΔΔCq method (21). All RT-qPCR reactions were performed in triplicates.

Western blotting. The cells were lysed using RIPA buffer (Sigma-Aldrich; Merck KGaA) and total protein concentration was quantified using the BCA protein assay kit (Sigma-Aldrich; Merck KGaA) following the manufacturer's instructions. Total protein (20 µg) was separated by 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis, transferred to PVDF membrane and blocked with TBS-Tween (0.1%) containing 5% bovine serum albumin (Sigma-Aldrich; Merck KGaA) at room temperature for 30 min, and probed with the specific primary antibodies at room temperature for 60 min. Anti-IRS-1 antibody (cat. no. ab52167), anti-Dvl2 antibody (cat. no. ab22616) and anti-β-actin antibody (cat. no. ab8226) were all bought from Abcam, and diluted in 1:2,000 before use. Then, the blot was incubated with specific horseradish peroxidase (HRP)-conjugated secondary antibodies (cat. nos. ab7090 or ab97040; Abcam) at dilution of 1:1,000, and the immunoreactive bands were imaged using enhanced chemiluminescence (Thermo Fisher Scientific, Inc.). The blots were analyzed using ImageJ software (version 2.0; National Institutes of Health).

Cell Counting Kit-8 (CCK-8) assay. For cell proliferation assay, 5x10^4 cells were seeded into 96-well plates and were analyzed at the indicated time points (24, 48, 72, 96 and 120 h). Then, 10 µl CCK-8 reagent (Sigma-Aldrich; Merck KGaA) was added into each well at 37°C for another 2-h incubation. The OD470 nm value was determined by a microplate reader (Synergy 2 Multi-Mode Microplate Reader; BioTek Instruments, Inc.).

Transfection. PcdNA3.1-Dvl2 plasmid was synthesized by Invitrogen (Thermo Fisher Scientific, Inc.), and empty vector pcDNA3.1 was employed as negative control. Small interfering (si) RNA target to IRS-1 (5’-CAAUGAGUGUGCAUAACUUC-3’), miR-144 mimic (5’-UACAGUAGUGAAGGUACU-3’), miR-144 inhibitor (5’-UACAGUAGUGAAGGUACU-3’) and corresponding negative controls were bought from Guangzhou RiboBio Co., Ltd. Lipofectamine® 2000 (Thermo Fisher Scientific, Inc.) was employed for transfection. For plasmid transfection, 1.6 µg of plasmid was used. For mimic, inhibitor and siRNA transfection, 50 µM of sample was employed following the manufacturer's instruction. After transfection (4 h), the cells were employed for further analyses.

Cell cycle analysis. The cells of interest were trypsinized and suspended with PBS, and then pelleted. After discarding the supernatant, cells were resuspended and fixed with ice-cold 70% ethanol. After 4 h, cells were pelleted and washed with ice-cold PBS, and suspended with 5 µg/ml propidium iodide (PI; Sigma-Aldrich; Merck KGaA) for 10 min in darkness at room temperature. Then, stained cells were analyzed using 3 laser Navios flow cytometers (Beckman Coulter, Inc.) and results were analyzed using FlowJo software (FlowJo LLC; version 9.7.4).

Scratch assay. When the cells reached 95% confluence, cells were scratched with a sterile plastic micropipette tip. After wounding, plates were washed three times with ice-cold PBS, and RIPM-1640 without FBS was added for 24-h incubation. After culturing for 24 h, images were captured by an inverted
fluorescence microscope (Nikon Corporation; magnification, x40) and the wound healing ability of each cell line was analyzed. Distances between the edges of the scratch were measured using ImageJ software (version 2.0; National Institutes of Health) to quantitatively evaluate cell migration. Cell migration was calculated according to the following formula: Cell migration ratio = 100 x (0 h scratch width - 24 h scratch width)/0 h scratch width.

Transwell assay. In order to analyze invasion capacity, 1x10^4 cells were suspended and plated into the upper chamber of Transwell inserts (8-µm pore size; Corning Inc.), coated with 0.3% Matrigel (Sigma-Aldrich; Merck KGaA) in RPMI-1640 medium without FBS addition, and maintained in an incubator at 37°C. In the lower chamber, 500 µl RPMI-1640 medium supplemented with 10% FBS was added. After 24-h incubation, the invaded cells were fixed with 4% paraformaldehyde at room temperature for 10 min and stained with 0.25% crystal violet (Sigma-Aldrich; Merck KGaA) at room temperature for 10 min. Invaded cells were then imaged under a X71 (U-RFL-T) fluorescence microscope (Olympus Corporation; magnification, x40).

Colony formation in soft agar. Collected cells were counted and resuspended in 0.3% low-melting soft agar in RPMI-1640 containing 10% FBS, then plated onto 0.6% solidified agar in RPMI-1640 containing 10% FBS in 6-well plates (5x10^3 cells/well). The samples were maintained at 37°C for 3 weeks. Colonies containing 50 cells or more were counted under a X71 (U-RFL-T) fluorescence microscope (Olympus Corporation; magnification, x40).

Statistical analysis. In the present study, all data are presented as the mean ± SD. One-way analysis of variance (ANOVA) was performed to compare multiple groups with one variable followed by Tukey’s post-hoc test. Significance between two groups was calculated by Student’s t-test. P<0.05 was considered to indicate a statistically significant difference.

Results

Expression of miR-144 post-transcriptionally regulates IRS-1 in NPC cells. In order to determine the expression level of miR-144 in NPC cell lines, RT-qPCR was performed to detect miR-144 level normalized to U6 RNA. It was observed that miR-144 was detected in all tested NPC cell lines with different expression profiles (Fig. 1A). The protein levels of IRS-1 in the cell lines were then detected by semi-quantitative western blotting. As shown in Fig. 1B, IRS-1 was detected in all these cell lines. By considering that the expression levels of miR-144 and IRS-1 are negatively correlated in NPC cell lines (Fig. 1A), it was hypothesized that miR-144 may post-transcriptionally regulate IRS-1 expression in NPC cells. To test this hypothesis, miR-144 inhibition or upregulation was performed using miR-144 inhibitor or miR-144 mimic, respectively. The results showed that miR-144 inhibition significantly decreased IRS-1 expression, while miR-144 upregulation significantly increased IRS-1 expression (Fig. 1C).

Colony formation in soft agar. Collected cells were counted and resuspended in 0.3% low-melting soft agar in RPMI-1640 containing 10% FBS, then plated onto 0.6% solidified agar in RPMI-1640 containing 10% FBS in 6-well plates (5x10^3 cells/well). The samples were maintained at 37°C for 3 weeks. Colonies containing 50 cells or more were counted under a X71 (U-RFL-T) fluorescence microscope (Olympus Corporation; magnification, x40).

Statistical analysis. In the present study, all data are presented as the mean ± SD. One-way analysis of variance (ANOVA) was performed to compare multiple groups with one variable followed by Tukey’s post-hoc test. Significance between two groups was calculated by Student’s t-test. P<0.05 was considered to indicate a statistically significant difference.
levels of miR-144 and IRS-1 were contrasting in NPC-TW01 and SUNE1 cells, these two cells were selected for further analysis. To confirm whether miR-144 post-transcriptionally regulates IRS-1, miR-144 inhibitor, miR-144 mimic, siIRS-1 or IRS-1 were efficiently transfected, confirmed by RT-qPCR (Fig. 1C), and IRS-1 protein was measured 48 h later. As shown in Fig. 1D, without affecting IRS-1 mRNA, the introduction of miR-144 inhibitor increased IRS-1 protein, whereas the miR-144 mimic downregulated the expression level of IRS-1 protein, which was similar to the observation following siIRS-1 transfection. Briefly, miR-144 post-transcriptionally regulates IRS-1.

**miR-144 inhibits cell proliferation by targeting IRS-1 in NPC cells.** In order to evaluate the effect of miR-144 on proliferation, the expression level of miR-144 in NPC-TW01 or SUNE1 was modified by introducing miR-144 inhibitor or miR-144 mimic. CCK-8 cell viability assay results presented that, in NPC-TW01 cells, both the inhibition of miR-144 and overexpression of IRS-1 significantly promoted cell proliferation, and in SUNE1 cells, both the introduction of miR-144 mimic and knockdown of IRS-1 significantly inhibited cell proliferation (Fig. 2A). The opposite effect of miR-144 and IRS-1 on cell proliferation indicated that miR-144 potentially regulates cell proliferation via regulating IRS-1. To further confirm the regulation of proliferation by miR-144, cell cycle was then assessed by flow cytometry. As shown in Fig. 2B, miR-144 expression significantly blocked the cell cycle at the G1/G0 phase, which is in contrast to the observation in the presence of IRS-1.

**miR-144 decreases malignant behaviors in NPC cells.** In order to further assess whether miR-144 is relevant in other malignant behaviors of NPC cells, cell migration, invasion and tumor formation in soft agar were examined after modification of miR-144 or IRS-1. As shown in Fig. 3A-C, in NPC-TW01 cells, inhibition of miR-144 and overexpression of IRS-1 promoted migration, invasion and colony formation in soft agar, and in SUNE1, the introduction of miR-144 mimic and knockdown of IRS-1 obviously inhibited migration, invasion and colony formation in soft agar. All these observations are consistent with the effect of miR-144 on proliferation, indicating that miR-144 exerted inhibitory effects not only on proliferation.

**miR-144 acts as a tumor suppressor potentially via down-regulating Dvl2 indirectly.** Accordingly, IRS-1 stabilizes Dvl2 and thus promotes malignant behaviors in cancer cells (20). Thus, whether miR-144 regulates Dvl2 protein level was further confirmed. As shown in Fig. 4A, miR-144 negatively regulated IRS-1 and Dvl2 without disturbing Dvl2 mRNA, indicating that miR-144 may regulate the proliferation of NPC cells via indirectly regulating Dvl2. Thus, Dvl2 was modified in NPC-TW01 and SUNE1 cells by efficiently introducing

After introducing miR-144 inhibitor, miR-144 mimic, siIRS-1 or IRS-1, (A) cell migration, (B) invasion and (C) tumor formation in soft agar were assessed. *P<0.05 vs. vector group. miR, microRNA; IRS-1, insulin receptor substrate 1; si, small interfering RNA; NC, negative control.

Figure 4. miR-144 inhibits cell proliferation via indirectly regulating Dvl2. (A) miR-144 regulates Dvl2 protein level without disturbing its mRNA level. (B) After transfecting the Dvl2-coding vector, reverse transcription-quantitative PCR was performed to detect Dvl1 mRNA level. *P<0.05 vs. vector group. (C) The knockdown efficacy of siRNA target to Dvl2 is confirmed by semi-quantitative western blotting. (D) The cell proliferation was measured after introducing miR-144 mimic, siDvl2, Dvl2 together or individually in nasopharyngeal carcinoma cells. *P<0.05 vs. control group. miR, microRNA; Dvl2, dishevelled 2; IRS-1, insulin receptor substrate 1; si/siRNA, small interfering RNA; NC, negative control.
a Dvl2-coding vector (Fig. 4B). As shown in Fig. 4C, Dvl2 protein expression was successfully modified despite the level of IRS-1. Then, cell proliferation was analyzed. In Fig. 4D, it was observed that the inhibitory effect of miR-144 on proliferation was significantly reversed by overexpression of Dvl2, demonstrating that the inhibitory effect of miR-144 on proliferation depends on the decrease in Dvl2.

Discussion

Accumulating evidence indicates that miRNAs exert roles in the pathogenesis of NPC by regulating tumour cell proliferation, metastasis, invasion and chemosensitivity (22). For example, Qiu et al (23) reported that in NPC cells, miR-29a/b targeted the COL3A1 and SPARC genes and thus enhanced cell migration, invasion and proliferation. Verhoeven et al (24) reported that miRNA and long non-coding RNA are regulated by high levels of EBV, and overexpressed miRNAs then promote malignant behaviors in NPC cells. It has also been reported that miR-24 promotes DNA methylation and then acts as a radiosensitizer in NPC cells. Further analysis revealed that miR-24 is downregulated in NPC tissues compared with adjacent tissues (25). The present study found that miR-144 expression is differentially expressed in different NPC cell lines, and its expression is negatively correlated with the IRS-1 level, which was reported to be a target that is downregulated post-transcriptionally. Overexpression of the miR-144 mimic remarkably decreased the malignant behaviors of NPCs, including proliferation, migration, invasion and tumour formation in soft agar. Conversely, the downregulation of miR-144, by introducing a specific inhibitor, promoted the aforementioned malignant behaviors. Zhang et al (8) reported that miR-144 promoted NPC malignancy by inhibiting PTEN expression, which is in contradiction with the present study results. The difference may be due to the different expression patterns of PTEN in different NPC cell lines, and it is worth investigating the roles of PTEN in additional NPC cell lines.

Dvl2 is mainly involved in the regulation of Wnt/β-catenin signaling (17). In recent research, Dvl2 was found to directly bind to the IRS-1 protein (20). IRS-1 binds to Dvl2 with or without insulin stimulation, and its overexpression increases the protein level of Dvl2, thus promoting canonical Wnt signaling and increasing the expression of CYCLIN D1 and C-MYC, which are recognized as oncogenes (20). Further research showed that the binding of IRS-1 to Dvl2 decreased ubiquitination and induced the stabilization of Dvl2. According to the present study results and consistent with previous findings, downregulation of IRS-1 by miR-144 introduction decreased the protein level of Dvl2. Although the binding of IRS-1 and Dvl2 was not investigated further, the presented results also demonstrated that the regulation of IRS-1 by miR-144 negatively regulated Dvl2. Moreover, the inhibitory effect of the miR-144 mimic on proliferation was significantly abolished by the exogenous expression of Dvl2, indicating that the regulatory effects of miR-144 are potentially, at least in part, dependent on the regulation of Dvl2.

IRS has been identified as a key player in the regulation of cell proliferation and epithelial mesenchymal transition (EMT), which is characterized by the expression levels of E-cadherin and N-cadherin. It has been reported that the overexpression of IRS-1 regulates the expression of E-cadherin during EMT (26,27) and cyclinD1 during cell proliferation (28). Although the hallmarks of EMT or the effects of miR-144 on EMT were not detected, by performing scratch and transwell assays, it was confirmed that miR-144 inhibited the migration and invasion of NPC cells, which was similar to the effect of IRS-1 knockdown being reversed by the introduction of a miR-144 inhibitor, indicating that miR-144 potentially regulates EMT. By considering that miR-144 post-transcriptionally regulates IRS-1 by direct binding (29), dual-luciferase reporter gene assay was not performed to prove that miR-144 post-transcriptionally regulates IRS-1, which is a limitation of the present study.

In conclusion, the present study findings show that miR-144 regulates IRS-1 and Dvl2. miR-144 inhibited the malignant behavior of NPC cells, including proliferation, migration, invasion and tumour formation, mainly via indirect regulation of Dvl2. The findings improve the understanding of the molecular mechanisms of miR-144 in the physiological processes of NPC cells. In future research, it is worth confirming whether miR-144 regulates EMT and the Wnt/β-catenin signaling pathway.
