Received: April 08, 2013; Revised: January 16, 2013; Accepted: August 04, 2013

Background: The importance of sialic acid binding adhesin (sabA) as a new outer membrane protein in gastroduodenal diseases has been recognized. The prevalence rate of sabA gene varies in different geographic areas.

Objectives: The aim of this study was to determine the frequency of sabA gene in Helicobacter pylori (H. pylori) strains isolated from different clinical outcomes in Tehran, Iran.

Patients and Methods: The study included 120 patients with dyspeptic symptoms admitted to the endoscopy suite of gastroenterology section of Firouzgar University Hospital, Tehran, Iran from March to August 2011. Gastric biopsy specimens were evaluated for the presence of H. pylori using standard microbiological method and polymerase chain reaction (PCR) assay. The sabA genopositive was determined by PCR in H. pylori strains.

Results: H. pylori isolates were recovered from 82 patients with duodenal ulcer (DU; n = 17), gastric ulcer (GU; n = 15), gastric cancer (GC; n = 13), and gastritis (G; n = 37). The frequency of sabA gene in H. pylori strains was 100% in gastric cancer, 86.7% in gastric ulcer, and 83.3% in both gastritis and duodenal ulcer.

Conclusions: This is a report on the prevalence of sabA gene in H. pylori isolated from different gastric patients in Iran. The results showed a high prevalence of sabA in our clinical H. pylori isolates.

Keywords: SabA protein, Helicobacter pylori; Gene Frequency; Gastric Ulcer

1. Background

Helicobacter pylori as a gram negative, curved, microaerophilic and motile organism with multiple polar flagella is the most common cause of gastric diseases including gastritis, duodenal and gastric ulcer, gastric atrophy, adenocarcinoma, and mucosa associated lymphoid tissue (MALT) (1). H. pylori infection is a major health problem in many parts of the world, occurring in 40 - 50% and 80 - 90% of the population in developed and developing countries respectively (2).

Several studies have shown that host and bacterial factors can play essential role in the appearance of clinical and pathologic complications. Among the bacterial factors, the ability of bacteria to bind to gastric epithelial cells is a crucial step for a successful infection, because it protects the bacteria from cleaning mechanisms such as fluid flow or pouring the mucous layers (3-7).

H. pylori has a wide range of adhesion components to bind to different carbohydrates. Sialic acid binding adhesion (sabA) plays a critical role in the initial colonization of H. pylori, and this molecule has an important role in the establishment of persistent infection and chronic inflammation, which causes tissue damage (8, 9).

sabA, a 70-kDa (651-aa protein) outer membrane protein, is essential for attachment and activation of human cells via sialyl-Lewis x/a antigens (sLex and sLea) (10).

2. Objectives

The clinical prevalence of the H. pylorisabA genotype has not yet been determined in clinical isolates in Iran. In this study, we investigated the presence of sabA gene in Iranian clinical H. pylori isolates with different clinical outcomes.

3. Patients and Methods

3.1. Study Population

One hundred twenty patients with dyspeptic symptoms...
were enrolled in the endoscopy suite of gastroenterology section of Firouzgar University Hospital, Tehran, Iran from March to August 2011. All patients were given informed consent for gastroscopic biopsy samples, which were obtained from the antrum.

3.2. Detection of H. pylori and the Presence of sabA Gene

Two gastric biopsy specimens were recovered from patients with gastrointestinal disease. One biopsy was evaluated for rapid urease test (RUT), and the other was sent to laboratory for DNA extraction. DNA was extracted using the DNeasy blood & tissue kit (Qiagen Germany). The sample was considered H. pylori positive when a 411bp fragment of urease A gene (ureA) was amplified and RUT made positive. For the H. pylori-positive samples, the presence of sabA in H. pylori clinical isolates was analyzed by PCR using two primer pairs. PCR primers are listed in Table 1. Amplification was performed as previously described (11-13). The PCR products were analyzed by 1% agarose gel electrophoresis with ethidium bromide staining.

| Target gene | Primer Sequence (5’–3’) | Size of PCR product | Reference |
|-------------|------------------------|--------------------|-----------|
| ureA | F-CCCAATGGTAAATTAGTT | 411bp | (11) |
| | R-CTCCTTAATGGTTTTTAC | | |
| sabA(Pair 1) | F-CTTTAAGGACATTTATGAAA | 785bp | (12,13) |
| | R-CACCGGCTATTGGTTGGGA | | |
| sabA(Pair 2) | F-CCGCTAGTGTCCAGGGTAAC | 1330bp | (12) |
| | R-CGGCCGTTAAGGTTTATGAAC | | |

3.3. Data analysis

Fisher’s exact test was used for analyzing categorical data. A P-value < 0.05 was considered statistically significant.

4. Results

From 120 patients, H. pylori isolates were recovered from 82 patients with duodenal ulcer (DU; n = 17), gastric ulcer (GU; n = 15), gastric cancer (GC; n = 13), and gastritis (G; n = 37). The mean age of the patients (50 male and 32 female) was 46 years. The presence of sabA gene was examined in all 82 of the H. pylori-infected patients with gastrointestinal diseases. The strains were considered sabA positive if they had one or two fragments of the gene. Two PCR assays yielded different positive rates for the sabA gene in 82 H. pylori isolates as shown in Table 2.

| Primer pair 1 | Primer pair 2 | Number |
|---------------|---------------|--------|
| +             | +             | 60     |
| -             | +             | 7      |
| +             | -             | 4      |
| -             | -             | 11     |

Seventy one strains (86.6%) had positive results for sabA. Table 3 shows the frequency of sabA gene among different clinical outcomes. The sabA genotype was detected in all patients with gastric cancer (100%), in 86.7% of patients with gastric ulcer, and in 83.3% of patients with gastritis and duodenal ulcer.

| Gene        | Clinical outcomes |
|-------------|-------------------|
| DU | GU | GC | G |
| PositivesabA | 15 | 13 | 13 | 30 |
| SabANegative | 3 | 2 | 0 | 6 |
| Total | 18 | 15 | 13 | 36 |

Figure 1 and 2 show the results of sabA gene amplification in some strains of H. pylori using primers pair 1 and 2 respectively.

5. Discussion

The adherence of H. pylori to gastric epithelial cells has a crucial role in the specific tropism and pathogenicity of the organism in the human gastric epithelium and is a key step in creating a successful infection in gastric mucosa (3,14-16). sabA is an important adhesion molecule in H. pylori which adheres to the host gastric epithelium (17). In a previous study performed on 200 H. pylori-infected patients, including 120 from Colombia and 80 from the United States, the prevalence rates of sabA-positive isolates were 44% in duodenal ulcer, 66% in gastritis, and 70% in gastric cancer (18). In a study in Taiwan, 80% (116 of 145) of H. pylori strains had positive results for sabA (19). In two other studies the frequency of sabA-positive isolates was reported 86% (37 of 43) and 93% (89/96) in French and Dutch respectively (20, 21). Moreover, the prevalence of sabA gene was 23.6% in Iran (22).
When compared to previous studies, our results showed that the sabA gene has high frequency in Iranian clinical isolates (86.6% (71 of 82)). The frequency of sabA in different clinical outcomes was 100% in gastric cancer, 86.7% in duodenal ulcer, and 83.3% in both gastritis and duodenal ulcer. However, no significant association was seen between the prevalence of sabA genotype and clinical outcomes (P > 0.05).

Two PCR assays produced different positive rates for the sabA gene in H. pylori isolates, with the 81.7% and 78% using primer pairs 1 and 2 respectively; indicating the possibility of sequence diversity in the sabA gene (12).

In conclusion, this is a report on the prevalence of sabA gene in H. pylori isolated from different gastric patients in Iran. More studies in other parts of country with a higher sample size are necessary to be performed to obtain a complete evaluation on the prevalence of sabA gene in Iran. Further tests should be performed to determine the exact role of sabA in H. pylori infection.
