A FOUR-VERTEX, QUADRATIC, SPANNING FOREST POLYNOMIAL
IDENTITY

ALEKSANDAR VLASEV AND KAREN YEATS

Abstract. The classical Dodgson identity can be interpreted as a quadratic identity of
spanning forest polynomials, where the spanning forests used in each polynomial are de-
defined by how three marked vertices are divided among the component trees. We prove an
analogous result with four marked vertices.

1. Introduction

Let $G$ be a graph with $m$ vertices, $n$ edges and let the $i$th edge be assigned a variable $\alpha_i$. Then we define the graph polynomial of $G$ as

$$
\Psi_G = \sum_{T \subseteq G} \prod_{e \in T} \alpha_e
$$

where the sum runs over the spanning trees $T$ of $G$. The reason why we pick edges not in
the trees is that this form arises naturally in quantum field theory, see for example [3, 5, 10].

We can also obtain this polynomial via the matrix-tree theorem. Let $A$ be the $n \times n$ diagonal
matrix with the variables $\alpha_i$. Orient the edges in the graph and let $E$ be the signed $m \times n$
incidence matrix for this orientation. Let $\hat{E}$ be the matrix $E$ with any row removed. Define
the $m+n$ by $m+n$ block matrix

$$
M_G = \begin{bmatrix}
A & \hat{E}^T \\
-\hat{E} & 0
\end{bmatrix}.
$$

Then the matrix-tree theorem states that

$$
\Psi_G = \det(M_G).
$$

To put this in the usual form of the matrix-tree theorem, note that $A$ is invertible, so we
can calculate the determinant using the Schur complement; in this case,

$$
\det(M) = \alpha_1 \cdots \alpha_n \det(0 - (-\hat{E}A^{-1}\hat{E}^T))
= \alpha_1 \cdots \alpha_n \det(\hat{E}A^{-1}\hat{E}^T)
$$

where $\hat{E}A^{-1}\hat{E}^T$ is the graph Laplacian with a row and column removed and with inverted
variables. See also Proposition 21 of [4].

There are two important ways to generalize $\Psi_G$ – one via the polynomials and one via the
matrix determinant. Let $P = P_1 \cup \cdots \cup P_k$ be a set partition of a set of vertices in $G$. Then
define the spanning forest polynomial for $G$ and $P$ as
\[
\Phi_P^G = \sum_{F \subseteq G} \prod_{e \in F} \alpha_e
\]
where the sum runs over spanning forests $F$ of $G$ composed of tree components $T_1, \ldots, T_k$ where the vertices $P_i$ are in tree $T_i$. Alternatively, let $I, J, K$ be sets of indices with $|I| = |J|$. Define the Dodgson polynomial $\Psi_{G,K}^{I,J}$ as
\[
\Psi_{G,K}^{I,J} = \det(M_G(I,J))_K
\]
where $M_G(I,J)$ is the submatrix obtained by removing the rows indexed by $I$ and the columns indexed by $J$ from $M_G$, and the subscript $K$ indicates that we are setting the variables $\alpha$ indexed by $K$ to 0. These two generalizations are related – every Dodgson polynomial can be expressed as a sum of signed spanning forest polynomials (see [7]). Thus we can use determinant identities to derive identities for spanning forest polynomials. For any square matrix $M$, we have the classical Dodgson identity
\[
\det(M(12,12)) \det(M) = \det(M(1,1)) \det(M(2,2)) - \det(M(1,2)) \det(M(2,1))
\]
which was popularized by Dodgson through his condensation algorithm [9]. Let $G$ be a graph of the form

with two edges labelled 1 and 2, connecting three vertices $v_1, v_2$ and $v_3$ from top to bottom. The Dodgson identity gives the spanning forest polynomial identity (see section 3)

\[(1)
\begin{array}{c}
\{1\} \\
\{2\} \\
\{3\}
\end{array}
= \begin{array}{c}
\{1\} \\
\{2\} \\
\{1\}
\end{array} + \begin{array}{c}
\{1\} \\
\{2\} \\
\{2\}
\end{array} + \begin{array}{c}
\{1\} \\
\{1\} \\
\{2\}
\end{array} + \begin{array}{c}
\{1\} \\
\{1\} \\
\{2\}
\end{array} + \begin{array}{c}
\{1\} \\
\{1\} \\
\{2\}
\end{array} + \begin{array}{c}
\{1\} \\
\{1\} \\
\{2\}
\end{array}
\end{array}
\]

where for example, the graph with labels 1, 1, 2 on the vertices $v_1, v_2, v_3$ represents $\Phi_P^G$ with $P = \{v_1, v_2\} \cup \{v_3\}$.

This result can be interpreted as saying that if we transfer an extra edge from the left hand factor of the left hand side to the right hand factor of the left hand side, thus cutting a spanning tree into two in the left hand factor and joining two of the three trees together in the right hand factor, then we get all pairs of spanning forests with exactly two trees. However, it is subtle to see that the counting matches on both sides, and seems to require chains of edges to be transferred, along the lines of the the combinatorial proof of the Dodgson identity due to Zeilberger [12].

Equation (1) and its combinatorial interpretation prompted us to investigate spanning forest polynomial identities of the form

\[
\begin{array}{c}
\{1\} \\
\{2\} \\
\{3\}
\end{array} = \begin{array}{c}
a_1 \\
a_2 \\
a_3
\end{array} \begin{array}{c}
b_1 \\
b_2 \\
b_3
\end{array} + \begin{array}{c}
c_1 \\
c_2 \\
c_3
\end{array} \begin{array}{c}
d_1 \\
d_2 \\
d_3
\end{array} + \cdots + \begin{array}{c}
e_1 \\
e_2 \\
e_3
\end{array} \begin{array}{c}
f_1 \\
f_2 \\
f_3
\end{array}
\end{array}
\]
Our work resulted in such an identity (Theorem 7) which is proved in this paper. For this result we cannot simply interpret a classical determinantal identity; the Jacobi identity on $M$ (see Corollary 9) naturally gives a cubic identity for such spanning forest polynomials, while the usual Dodgson identities on submatrices of $M$ can only relate spanning forest polynomials whose degrees differ by at most 2. Rather, we need to combine classical identities in nontrivial ways.

The paper is organized as follows: In section 2 we will set up our definitions. In section 3 we will define spanning forest polynomials and give their relation to the minors of $M$. The main result itself is presented and proved in section 4. Finally, in section 5 we conclude with a discussion of the main result, its combinatorial interpretations, and possible extensions.

2. Graph polynomials

Definition 1. Let $G$ be a graph and let $M_G$ be a matrix built as in the previous section. Then we define

$$\Psi_G = \det(M_G)$$

By the matrix-tree theorem, $\Psi_G$ is independent of the choice of $M_G$. We will call $\Psi_G$ the graph polynomial or Kirchhoff polynomial of $G$. We fix a choice of $M = M_G$ for $G$.

Definition 2. Let $I$, $J$, and $K$ be subsets of the edges of $G$ with $|I| = |J|$. Let $M(I, J)_K$ be the matrix obtained from $M$ by removing the rows indexed by edges of $I$, the columns indexed by edges of $J$, and setting $\alpha_i = 0$ for all $i \in K$. Then we define the Dodgson polynomials

$$\Psi^{I, J}_{G, K} = \det M(I, J)_K$$

When $G$ is clear it will be suppressed from the notation. Also, if $K = \emptyset$ we may suppress it from the notation.

Up to sign these polynomials are independent of the choice of $M$ (see [4]). By definition it is evident that $\Psi^{\emptyset, \emptyset}_{G, \emptyset} = \Psi_G$. Note that if any element of $K$ appears in $I$ or $J$ then it does not appear in $M(I, J)$, so setting it to zero has no effect.

Contraction and deletion of edges is natural at the level of Dodgson polynomials.

Proposition 3. Let $G$ be a graph and let $e_i$ denote the $i$-th edge in $G$. Then

$$\Psi^{i, i}_{G} = \Psi_{G \setminus e_i}$$
$$\Psi_{G, i} = \Psi_{G/e_i}$$

Proof. The first identity follows immediately from the matrix definition of $\Psi$ and the second from the sum of spanning trees definition. □

The all-minors matrix-tree theorem [8] tells us that the monomials of any $\Psi^{I, J}_{G, K}$ result from spanning forests of $G$. For our purposes it is most useful to organize these spanning forests with the following spanning forest polynomials.

Definition 4. Let $P = P_1 \cup P_2 \cup \cdots \cup P_k$ be a set partition of a subset of the vertices of $G$. Then we define

$$\Phi^P_G = \sum_{F} \prod_{e \not\in F} \alpha_e$$
where the sum runs over spanning forests $F = T_1 \cup T_2 \cup \cdots \cup T_k$ with $k$ component trees so that the vertices of $P_i$ are in tree $T_i$. We note that we are allowing trees consisting of a single vertex.

The relation between Dodgson polynomials and spanning forest polynomials is given by the following proposition.

**Proposition 5.**

\[
\Psi_{G,K}^{I,J} = \sum_P \pm \Phi_{G\setminus(I\cup J\cup K)}^P
\]

where the sum runs over set partitions $P$ of the end points of edges of $I$, $J$, and $K$ with the property that the forests corresponding to each set partition become trees in both $G\setminus I/(J \cup K)$ and $G\setminus J/(I \cup K)$.

**Proof.** For the full details, see Proposition 12 of [7]. To sketch the argument, equation (2) is a direct consequence of two facts. Let $\hat{E}[S]$ be the submatrix of $\hat{E}$ consisting of columns indexed by $S$. First, the coefficient of a given monomial $m$ in $\Psi_{K}^{I,J}$ is

\[
\det \begin{bmatrix} 0 & \hat{E}[J \cup K \cup F]^T \\ -\hat{E}[I \cup K \cup F] & 0 \end{bmatrix}
\]

where $F$ is the forest corresponding to $m$ (that is the edges of $G\setminus(I \cup J \cup K)$ which do not contribute to $m$). This fact follows directly from the form of $M$. Second, a square matrix formed of columns of $\hat{E}$ has determinant $\pm 1$ if the edges corresponding to those columns are a spanning tree of $G$, and has determinant 0 otherwise. This fact is the matrix-tree theorem in its most stripped down form, see for example [3] Lemma 20. \hfill □

3. The classical Dodgson identity

In this section we interpret the classical Dodgson identity in terms of spanning forest polynomials. Consider the graph $G$

\[
\begin{array}{c}
1 \\
2
\end{array}
\]

Apply the Dodgson determinant identity to the matrix $M$ for $G$

\[
\det(M(1,1)) \det(M(2,2)) - \det(M(1,2)) \det(M(2,1)) = \det(M) \det(M(12,12))
\]

Interpreting this in terms of Dodgson polynomials gives

\[
\Psi_G^{1,1} \Psi_G^{2,2} - \Psi_G^{1,2} \Psi_G^{1,2} = \Psi_G \Psi_G^{12,12}
\]

and after setting the variables for edges 1 and 2 to 0 we obtain

\[
\Psi_G^{1,1} \Psi_G^{2,2} - (\Psi_G^{1,2})^2 = \Psi_G \Psi_G^{12,12}.
\]

For a generalization, see Corollary [10]. Using the deletion-contraction relations we obtain

\[
\Psi_{G\setminus e_1/e_2} \Psi_{G\setminus e_2/e_1} - (\Psi_G^{1,2})^2 = \Psi_G \Psi_{G\setminus \{e_1,e_2\}}
\]
and converting to spanning forest polynomials we find that
\[
\left( \Phi_H^{\{a,c\},\{b\}} + \Phi_H^{\{a\},\{b,c\}} \right) \left( \Phi_H^{\{a,b\},\{c\}} + \Phi_H^{\{a,c\},\{b\}} \right) = \Phi_H^{\{a,b,c\},\{a\},\{b\},\{c\}}
\]
where \( H \) is the graph with edges 1 and 2 removed. Rearranging and cancelling the squared term we find that
\[
\Phi_H^{\{a,b,c\},\{a\},\{b\},\{c\}} = \Phi_H^{\{a,b\},\{c\}} \Phi_H^{\{a\},\{b,c\}} + \Phi_H^{\{a,b\},\{c\}} \Phi_H^{\{a\},\{b,c\}} + \Phi_H^{\{a,b\},\{c\}} \Phi_H^{\{a\},\{b,c\}}
\]
which is just equation (1) written in the spanning forest polynomial notation. See Proposition 22 in [7] for more details.

4. The main result

In section 3 we gave the spanning forest polynomial version of the Dodgson identity. The main result of this paper is an analogous spanning forest polynomial identity for 4 marked vertices. Let us specialize our notation to this situation.

**Definition 6.** Let \( v_1, v_2, v_3, \) and \( v_4 \) be four distinct vertices of a graph \( G \). We will write \( (c_1, c_2, c_3, c_4) \) with \( c_i \in \{1, 2, 3, 4, -\} \) to denote the spanning forest polynomial of the graph \( G \) defined by the partition of \( \{v_i : c_i \neq -\} \) with one part for each distinct integer \( \ell \) in \( (c_1, c_2, c_3, c_4) \) defined by \( \{v_i : c_i = \ell\} \), and no other parts. Particularly useful are the following special cases

\[
A_1 = (1, 1, 2, 3), \quad A_2 = (1, 2, 1, 3), \quad A_3 = (1, 2, 2, 3), \\
A_4 = (1, 2, 3, 1), \quad A_5 = (1, 2, 3, 2), \quad A_6 = (1, 2, 3, 3)
\]

of 3 marked vertices each, the following cases

\[
B_1 = (1, 1, 1, 2), \quad B_2 = (1, 1, 2, 1), \quad B_3 = (1, 2, 1, 1), \\
B_4 = (1, 2, 2, 2), \quad B_5 = (1, 1, 2, 2), \quad B_6 = (1, 2, 1, 2), \\
B_7 = (1, 2, 2, 1)
\]

of 3 marked vertices each, and finally let

\[
P = (1, 1, 1, 1)
\]

The \( A_i \) and \( B_i \) are the different ways in which we can partition four vertices in 3 and 2 sets respectively. \( P \) is just \( \Psi_G \) for this \( G \) with four marked vertices.
Theorem 7. Let $G$ be a graph with four marked vertices. Then
\[
(1, 1, 1, 1)(1, 2, 3, 4) = (1 - x_1 - x_2)A_4B_1 + x_7A_2B_4 + (1 - x_3 - x_2)A_5B_1 \\
+ (1 - x_1 - x_4)A_6B_1 + x_2A_2B_2 + (x_3 + x_2 - x_5)A_3B_2 \\
+ (1 - x_1 - x_6)A_6B_2 + x_1A_1B_3 + (x_1 - x_7 + x_4)A_4B_3 \\
+ (x_1 - x_8 + x_6)A_5B_3 + x_5A_1B_4 + (x_1 - x_5 + x_4)A_3B_5 \\
+ (x_1 - x_5 + x_6)A_5B_5 + x_3A_1B_6 + (x_3 + x_2 - x_7)A_3B_6 \\
+ (1 - x_1 - x_2 + x_8 - x_6)A_4B_6 + (x_2 + x_7 - x_4)A_2B_7 \\
+ (1 - x_1 - x_7 + x_8 - x_6)A_6B_6 + (x_1 + x_5 - x_3)A_1B_7 \\
+ (1 + x_5 - x_3 - x_2 - x_8)A_5B_7 \\
+ (1 - x_1 + x_7 - x_4 - x_8)A_6B_7 \\
+ x_8A_4B_4 + x_4A_2B_5 + x_6A_4B_5
\]
for any $x_1, \ldots, x_8$.

This is the generalization of the classical Dodgson identity phrased in terms of spanning forest polynomials. It is possible to give a graphical representation of this identity like in equation [1] but it would take too much space.

Outline of proof. Here we will describe the structure of the proof and the necessary calculations will be carried out in the results which follow this outline.

Let $E(x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8)$ be the right hand side of (3). We first check that $E$ does not depend on the values of the $x_i$ by checking that the coefficient of each $x_i$ in $E$ is zero (Proposition 14). Now we are free to use any choice of $x_i$ which is algebraically convenient.

Next, using the classical Jacobi identity on an auxiliary graph with three extra edges we obtain an expression for
\[
(1, 2, 3, 4)^2(1, 1, 1, 1)
\]
which is a linear combination of products of the form $A_iA_j$ (Lemma 15).

Then we calculate each $PA_i$ as a linear combination of products of the form $A_jB_k$ (Lemma 16). Using this calculation we obtain an expression for \((1, 2, 3, 4)(1, 1, 1, 1)\)^2, which we can then check is the same as $E(0, 0, 0, 0, 0, 0, 0, 0)E(0, 1, 0, 1, 1, 1, 1, 1)$ (Lemma 17).

The proof of the theorem concludes by checking the sign. □

Let us pause here for a brief word on the role of the $x_i$. The Dodgson identities give a number of quadratic identities between the $A_i$ and $B_i$. Consequently there cannot be a unique way to write $(1, 1, 1, 1)(1, 2, 3, 4)$ as a linear combination of products $A_iB_k$. The $x_i$’s describe this nonuniqueness. We can specialize to get more manageable equations, for example setting all $x_i = 0$ and collecting terms gives
\[
(1, 2, 3, 4)(1, 1, 1, 1) = (1, 2, 3, 1)(1, -1, 1, 2) + (1, 2, 3, 2)(-1, 1, 1, 2) + (1, 2, 3, 3)(-1, -1, 1, 2)
\]
but no such specialization is canonical, so we gave the general equation in Theorem 7.

4.1. Preliminary results. Now we can proceed with the lemmas. We will need a particular form of the Jacobi determinantal identity and some further Dodgson identities which follow from it.
Let $M$ be an $n \times n$ matrix. Let $I$ and $J$ be subsets of $\{1, 2, \ldots, n\}$. Let $M(I, J)$ be the matrix obtained from $M$ by removing rows $I$ and columns $J$. Similarly let $M[I, J]$ be the matrix where we only keep rows $I$ and columns $J$. Finally we let
\[ s(I, J) = \sum_{x \in I} x + \sum_{x \in J} x. \]

**Theorem 8.** Let $M$ be a nonsingular $n \times n$ matrix and let $I$ and $J$ be two sets in $\{1, 2, \ldots, n\}$ with $|I| = |J| = t$. Let $A = \text{adj } M$ and define the matrix $B$ by $b_{ij} = \det(M(i, j))$. Then
\[ \det(B[I, J]) = (\det M)^{t-1} \det(M(I, J)). \]

**Proof.** To remain self contained we will give a proof following the idea of the proof of Lemma 28 of [4]. Let $I_n$ be the $n \times n$ identity matrix. Then $AM = I_n (\det M)$

Take determinants to get
\[ \det(A) = \det M^{n-1}. \]

Now if the $k$-th element of $I$ is $i_k$ and the $k$-th element of $J$ is $j_k$ let $C$ be $M$ with the $j_k$ column replaced by $e_{i_k}$, where $e_i$ is the $i$-th standard basis element of $\mathbb{R}^n$. Then multiplying out column by column we get that $AC$ is the matrix $D$ whose $j_k$-th column is
\[ \begin{cases} (\det M)e_j & \text{if } j \text{ is not in } J \\ Ae_{i_k} & \text{if } j = j_k \text{ in } J \end{cases} \]

Now notice that
\[ \det C = (-1)^{s(I, J)} \det(M(I, J)) \]
and
\[ \det D = (\det M)^{n-t} \det(A[J, I]) = (\det M)^{n-t} \det(B[I, J]) (-1)^{s(I, J)}. \]

The second equality holds since $A[J, I]$ can be converted to $B[I, J]$ by multiplying each row and each column which had an odd index in $M$ by $-1$ and then taking a transpose; on determinants this changes the sign $s(I, J)$ times.

Finally, taking the determinant of $AC = D$, using the above calculations and dividing by $(\det M)^{n-t}$ gives us the result. \qed

This formula can readily be translated into the Dodgson polynomials language.

**Corollary 9.** Let $G$ be a graph and $M$ be its associated matrix. Let $I$, $J$ and $E$ be subsets of the edges, such that $|I| = |J| = k$. Then the $k$-level Dodgson identity is
\[ \det \left( \Psi_{G,E}^{I,J} \right)_{1 \leq i, j \leq k} = \Psi_{G,E}^{I,J} (\Psi_{G,E})^{k-1} \]
where $I = \{I_1, \ldots, I_k\}$ and $J = \{J_1, \ldots, J_k\}$.

**Proof.** Use Theorem 8. By definition $\det M = \Psi_G$ and $\det M(I, J) = \Psi_{G}^{I,J}$. Now $B[I, J]_{ij} = \det(M(I_i, J_j)) = \Psi_{G}^{I_i,J_j}$. Finally we set $\alpha_e = 0$ for $e \in E$. \qed

Careful book-keeping and application of the above identity yield the following corollary.
Corollary 10. Let $M$ be an associated matrix for the graph $G$. Let $E$, $I$, $J$, $A$ and $B$ be ordered sets indexing edges in $G$, such that $|A \cap I| = |B \cap J| = 0$, $|I| = |J| = k$ and $|A| = |B| = l$. Then the modified $k$-level Dodgson identity is

$$
(4) \quad \det \left( \Psi_{G,E}^{A \cup I, B \cup J} \right)_{1 \leq i,j \leq k} = \Psi_{G,E}^{A \cup I, B \cup J} \left( \Psi_{G,E}^{A,B} \right)^{k-1}
$$

where $I = \{I_1, \ldots, I_k\}$ and $J = \{J_1, \ldots, J_k\}$.

Note that when $k = 2$ this gives the classical Dodgson identity.

We will use the following rearrangement of the $k = 2$ case.

**Proposition 11** (Brown, [4]). Let $I$ and $J$ be subsets of edges of $G$ with $|J| = |I| + 1$. Let $a, b, x$ be edges indices with $a \notin I$, $b, x \notin I \cup J$, and $x < a < b$. Let $S = I \cup J \cup \{a, b, x\}$. Then

$$
(5) \quad \Psi_S^{Ia,J} \Psi_S^{Ib,Jx} - \Psi_S^{Iax,Jx} \Psi_S^{Ib,J} = \Psi_S^{Ia,J} \Psi_S^{Iab,Jx}
$$

**Proof.** This is equation 23 from [4]; the proof proceeds by applying the $k = 2$ case of (4) three times and rearranging.

We only need the signs relating Dodgson polynomials to spanning forest polynomials in two cases, given in the next lemma. The general formula is found in Proposition 16 of [7], but we give here a self contained proof of the cases we need.

**Lemma 12.** Fix an order and orientation of the edges of a graph $G$. Suppose edges 1, 2, and 3 have a common vertex $v$. Let $w_1$, $w_2$, and $w_3$ be distinct and be the other end points of 1, 2, and 3, and let

$$
\epsilon(i,j) = \begin{cases} 
1 & \text{if } i \text{ and } j \text{ are both oriented into } v \text{ or both oriented out of } v \\
-1 & \text{otherwise}
\end{cases}
$$

for $i \neq j \in \{1, 2, 3\}$. Then

$$
\Psi^{1,2} = \epsilon(1, 2) \Phi^{\{v\},\{w_1, w_2\}}
$$

and

$$
\Psi^{i,j}_k = \epsilon(i,j)(-1)^{i-j+1} \Phi^{\{v\},\{w_i, w_j\},\{w_k\}}
$$

where $\{i, j, k\} = \{1, 2, 3\}$ in some order.

**Proof.** The first statement of the lemma follows from the second with $k = 3$ applied to the graph $G$ with a new vertex $w_3$ added and a new edge 3 from $v$ to $w_3$. Consider the second statement. Let $x$ be the vertex which was removed when forming $M$. We choose it to be disjoint from $\{v, w_i, w_j\}$.

Note that $\{v\},\{w_i, w_j\},\{w_k\}$ is the only set partition compatible with $\Psi^{i,j}_k$. From the observations preceding this lemma, if $\Psi^{i,j}_k = 0$ then there are no common spanning trees of $G\backslash i/\{j, k\}$ and $G\backslash j/\{i, k\}$ and so in particular there are no terms in $\Phi^{\{v\},\{w_i, w_j\},\{w_k\}}$. Thus

$$
\Psi^{i,j}_k = 0 \iff \Phi^{\{v\},\{w_i, w_j\},\{w_k\}} = 0.
$$

By [2] we know that $\Psi^{i,j} = f \Phi^{\{v\},\{w_i, w_j\},\{w_k\}}$ for some $f \in \{-1, 1\}$, so it suffices to consider one term of $\Psi^{i,j}$. Pick a term $t$ where the tree out of $w_i$ and $w_j$ intersects $x$. Let $F$ be the
forest corresponding to \( t \). The sign of \( t \) in \( \Psi^{i,j} \) is \( \det N \) where

\[
N = \begin{bmatrix}
0 & \hat{E}[[i,k] \cup F]^T \\
-\hat{E}[[j,k] \cup F] & 0
\end{bmatrix}
\]

Let \( B = \hat{E}[[k] \cup F] \). Then \( \hat{E}[[i,k] \cup F] \) and \( \hat{E}[[j,k] \cup F] \) are formed by inserting the \( i \)th and \( j \)th columns respectively of \( \hat{E} \) into \( B \). If \( \{i,j\} = \{1,2\} \) the insertions are both made in the first column. Let \( i' \) be the index of the inserted column \( i \) and \( j' \) the index of the inserted column in \( j \). Thus if \( \{i,j\} = \{1,2\} \) then \( i' = j' = 1 \); if \( \{i,j\} = \{1,3\} \) then \( \{i',j'\} = \{1,2\} \); and if \( \{i,j\} = \{2,3\} \) then \( i' = j' = 2 \).

Consider \( B \) with the row corresponding to \( v \) removed. This is the same as the columns corresponding to edges of \( \{k\} \cup F \) in the incidence matrix of the graph with \( v \) and \( x \) identified. This has determinant \( \pm 1 \) since \( \{k\} \cup F \) was chosen to be a tree in this graph. Likewise, removing the row corresponding to \( w_1 \) or \( w_2 \) we get a zero determinant since \( \{k\} \cup F \) is not a tree in the graph with \( w_1 \) or \( w_2 \) identified with \( x \).

Thus if we expand \( \det \hat{E}[[i,k] \cup F] \) down the inserted column, only the cofactor coming from row \( v \) is retained, and likewise for \( \hat{E}[[j,k] \cup F] \). Thus

\[
\det N = \det(\hat{E}[[i,k] \cup F]) \det(\hat{E}[[j,k] \cup F])
= e_{i,\ell}e_{j,\ell}(-1)^{i'+j'+2\ell} \det(\hat{B})^2
= \epsilon(i,j)(-1)^{i-j+1}
\]

where \( \ell \) is the index of row \( v \), \( \hat{B} \) is \( B \) with row \( v \) removed and \( e_{r,s} \) is the \((r,s)\) entry of \( \hat{E} \). \( \square \)

4.2. Results for the main argument. Here is a catalogue of the instances of the Dodgson identity which we will need in the main argument, written in terms of the \( A_i \) and \( B_i \) from Definition 6.

Lemma 13.

\[
\begin{align*}
(6) & \quad A_1(B_3 + B_7) + A_2(B_7 - B_5) - A_4(B_1 + B_5) = 0 \\
(7) & \quad A_1(B_4 + B_7) + A_5(B_7 - B_5) - A_3(B_2 + B_5) = 0 \\
(8) & \quad A_2(B_2 + B_7) + A_1(B_7 - B_6) - A_4(B_1 + B_6) = 0 \\
(9) & \quad A_2(B_4 + B_7) + A_6(B_7 - B_6) - A_3(B_3 + B_6) = 0 \\
(10) & \quad A_3(B_2 + B_6) + A_1(B_6 - B_7) - A_5(B_1 + B_7) = 0 \\
(11) & \quad A_3(B_3 + B_5) + A_2(B_5 - B_7) - A_6(B_1 + B_7) = 0 \\
(12) & \quad A_4(B_4 + B_5) + A_5(B_5 - B_7) - A_6(B_2 + B_7) = 0 \\
(13) & \quad A_4(B_4 + B_6) + A_6(B_6 - B_7) - A_5(B_3 + B_7) = 0 \\
(14) & \quad A_5(B_3 + B_5) + A_4(B_5 - B_6) - A_6(B_2 + B_6) = 0 
\end{align*}
\]
Proof. The equations differ only by permuting the four marked vertices, so it suffices to prove (7). Consider the graph

We use identity (5) with $x = 1, a = 2, b = 3, I = \emptyset$ and $J = \{2\}$, and by Lemma 12 we obtain

$$
(1, -, 2, 3)(1, 2, 2, -) - (1, -, 2, -)(1, 2, 2, 3) = (1, 2, 3, 2)(1, -, 2, 2).
$$

For the sign of $(1, -, 2, 2)$ note that the cutting happens first so that edges 1 and 3 become adjacent columns in the cut matrix. Expanding, $(1, -, 2, 2) = A_1 + A_3 + A_5$, $(1, 2, 2, -) = B_4 + B_7$, $(1, -, 2, -) = B_2 + B_4 + B_5 + B_7$, and $(1, -, 2, 2) = B_4 + B_5$. We substitute these in and rearranging gives us equation (7). 

Proposition 14. All the free variables in (3) are explained by Dodgson identities.

Proof. The coefficient of $x_3$ in equation (3) is the right hand side of equation (10), and thus is 0. Similarly the coefficients of $x_4, x_5, x_6, x_7, x_8$ are zero by (11), (7), (14), (9), and (13) respectively. The coefficient of $x_2$ is in a different form, but is also zero as it is the sum of the right hand sides of (8) and (10). Finally, the coefficient of $x_1$ is the sum of the right hand sides of (14), (11), and (6) and so is zero.

Lemma 15. 

$$(1, 1, 1, 1)(1, 2, 3, 4)^2 = \det \begin{pmatrix} A_1 + A_3 + A_5 & -A_3 & -A_5 \\ -A_3 & A_2 + A_3 + A_6 & -A_6 \\ -A_5 & -A_6 & A_4 + A_5 + A_6 \end{pmatrix}$$

Proof. Let $H$ be $G$ with three new edges 1, 2 and 3 connecting vertex $v_1$ with the other 3 marked vertices. By Corollary 9 with $k = 3$ and $I = J = E = \{1, 2, 3\}$ we have

$$(\Psi_{H,123})^2 \Psi_{H,123}^{123} = \det \begin{pmatrix} \Psi_{H,23}^{1,1} & \Psi_{H,3}^{1,2} & \Psi_{H,2}^{1,3} \\ \Psi_{H,3}^{1,2} & \Psi_{H,13}^{2,2} & \Psi_{H,1}^{2,3} \\ \Psi_{H,2}^{1,3} & \Psi_{H,1}^{2,3} & \Psi_{H,12}^{3,3} \end{pmatrix}$$

where $\Psi_{H,123}^{123}$ is the graph polynomial of $G$ with the edges 1,2 and 3 removed, namely $\Psi_{H,123} = P = (1,1,1,1)$; $\Psi_{H,123}$ is the spanning forest polynomial of $G$ where each of the four vertices is in a separate tree, namely $\Psi_{H,123} = (1,2,3,4)$.

The Dodgson polynomials on the main diagonal are just spanning forest polynomials of $G$ where one of the edges is removed and the other two contracted. By inspection, these are precisely the terms in the diagonal of the matrix in the result. The Dodgson polynomials on the off-diagonals require more care. We orient the edges like this: edge 2 goes towards vertex 1 and the other two away from it.
This ensures all the off-diagonal signs are negative (by Lemma 12) and that each Dodgson polynomial gives the desired spanning forest polynomial. The result follows. □

Note that the matrix in Lemma 15 is the Laplacian matrix with row and column 1 removed for the following graph

where the edge labels are the $A$’s. This is not a coincidence and there is a general identity which we leave out for brevity. However, the statement is analogous.

To complete the calculation we need to multiply the whole expression by $P$ and use the following

**Lemma 16.**

\[
PA_1 = B_1B_2 + B_1B_5 + B_2B_5 + B_5B_6 + B_5B_7 - B_6B_7 \\
PA_2 = B_1B_3 + B_1B_6 + B_3B_6 + B_5B_6 - B_5B_7 + B_6B_7 \\
PA_3 = B_1B_4 + B_1B_7 + B_4B_7 - B_5B_6 + B_5B_7 + B_6B_7 \\
PA_4 = B_2B_3 + B_2B_7 + B_3B_7 - B_5B_6 + B_5B_7 + B_6B_7 \\
PA_5 = B_2B_4 + B_2B_6 + B_4B_6 + B_5B_6 - B_5B_7 + B_6B_7 \\
PA_6 = B_3B_4 + B_3B_5 + B_4B_5 + B_5B_6 + B_5B_7 - B_6B_7
\]
Proof. By symmetry of the four vertices it suffices to prove the formula for \(PA_1\). Consider the graph

Then

\[
PA_1 = -\Psi_{123,123}^{13,13} \text{ by Lemma 12}
\]

\[
= \Psi_{12,32}^{13,13} - \Psi_{12,31}^{13,23} \text{ by (4) with } A = \{1\}, B = \{3\}, I = \{2, 3\}, J = \{1, 2\}, \text{ and } E = \{1, 2, 3\}
\]

\[
= (1, 1, 2, -)(-,-,1,2) - (1,-,2,1)(-1,2,1) \text{ by Lemma 12}
\]

\[
= (B_2 + B_5)(B_1 + B_2 + B_6 + B_7) - (B_2 + B_7)(B_2 + B_6)
\]

\[
= B_1B_2 + B_1B_5 + B_2B_5 + B_3B_6 + B_3B_7 - B_6B_7
\]

\[\square\]

Now we find out what happens when we multiply the equation in Lemma 15 by \(P\).

Lemma 17.

\[((1,1,1,1)(1,2,3,4))^2 = E(0,0,0,0,0,0,0,0)E(0,1,0,1,1,1,1,1)\]

where \(E(x_1,x_2,x_3,x_4,x_5,x_6,x_7,x_8)\) is the right hand side of (3).

Proof. By definition

(16) \[E(0,0,0,0,0,0,0,0) = (A_5 + A_6)(B_1 + B_7) + A_6(B_2 + B_6) + A_4(B_1 + B_6)\]

and

(17) \[E(0,1,0,1,1,1,1) = (A_1 + A_2)(B_4 + B_7) + A_2(B_2 + B_5) + A_4(B_4 + B_5)\]

Use Lemma 15 and 16 to calculate \(((1,1,1,1)(1,2,3,4))^2\). With some trial and error we chose which lines of Lemma 16 to use so that the final result would look as much as possible like the product of (16) and (17). The term \(((1,1,1,1)(1,2,3,4))^2\) equals

\[
(A_1 + A_2)(PA_3)(A_5 + A_6) + A_2(PA_1)(A_5 + A_6) + (A_1 + A_2)(PA_5)A_6
\]

\[
+ A_4(A_1 + A_2 + A_5 + A_6)(PA_3) + A_4(A_2 + A_6)(PA_1 + PA_5)
\]

\[
= (A_1 + A_2)(A_5 + A_6)(B_1B_7 + B_4B_7 + B_1B_4)
\]

\[
+ A_2(A_5 + A_6)(B_1B_2 + B_2B_5 + B_1B_5 + B_5B_7)
\]

\[
+ (A_1 + A_2)A_6(B_2B_6 + B_4B_6 + B_2B_3 + B_6B_7)
\]

\[
+ A_4(A_1 + A_2 + A_5 + A_6)(B_1B_7 + B_4B_7 + B_1B_4 + B_5B_7 + B_6B_7)
\]

\[
+ A_4(A_2 + A_6)(B_1B_5 + B_2B_5 + B_1B_2 + B_2B_6 + B_4B_6 + B_2B_4 + B_5B_6)
\]
Now we consider the difference between this expression and \([16]\) times \([17]\)
\[
A_1 A_5(-B_7^2 - B_5 B_6 + B_5 B_7 + B_6 B_7) + A_1 A_6(-B_7^2 + B_5 B_6 - B_2 B_7 + B_6 B_7)
+ A_2 A_5(-B_7^2 + B_2 B_5 - B_5 B_7 + B_6 B_7) + A_2 A_6(-B_7^2 - 2B_2 B_7 - B_5^2)
\]
\[
+ A_4 A_5(B_1 B_7 + B_6 B_7 - B_1 B_5 - B_5 B_6) + A_4 A_6(B_1 B_7 + B_6 B_7 + B_1 B_2 + B_2 B_6)
+ A_1 A_4(B_4 B_7 + B_5 B_7 - B_6 B_4 - B_5 B_6) + A_2 A_4(B_4 B_7 + B_5 B_7 + B_2 B_5 + B_2 B_4)
\]
\[
- A_1^2(B_1 + B_6)(B_4 + B_5)
= -(A_6(B_2 + B_7) - A_5(B_5 - B_7))(A_2(B_2 + B_7) - A_1(B_6 - B_7))
\]
\[
- A_4 A_5(B_1 + B_6)(B_5 - B_7) + A_4 A_6(B_1 + B_6)(B_2 + B_7)
- A_1 A_4(B_4 + B_5)(B_6 - B_7) + A_2 A_4(B_2 + B_7)(B_5 + B_4) - A_4^2(B_1 + B_6)(B_4 + B_5)
= -A_4 B_4 + B_5)(A_2(B_2 + B_7) - A_1(B_6 - B_7)) \quad \text{by } [12]
\]
\[
- A_4 A_5(B_1 + B_6)(B_5 - B_7) + A_4 A_6(B_1 + B_6)(B_2 + B_7)
- A_1 A_4(B_4 + B_5)(B_6 - B_7) + A_2 A_4(B_2 + B_7)(B_5 + B_4) - A_4^2(B_1 + B_6)(B_4 + B_5)
\]
\[
= A_4 B_1 + B_6)(A_6(B_2 + B_7) + A_5(B_7 - B_5) - A_4(B_4 + B_5))
= 0 \quad \text{by } [12]
\]
\]

We are now ready to finish the proof of the main theorem.

Proof of Theorem 7. By Lemma 17 we know that
\[
E(0, 0, 0, 0, 0, 0, 0, 0) E(0, 1, 0, 1, 1, 1, 1, 1) = ((1, 2, 3, 4)(1, 1, 1, 1))^2
\]
and by Proposition 14 we know that \(E\) does not depend on the \(x_i\). Thus we have
\[
E(x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8) = \pm(1, 2, 3, 4)(1, 1, 1, 1)
\]
It remains to check the sign. Note that \((1, 1, 1, 1) = P = \Psi_G\) and \((1, 2, 3, 4)\) is \(\Psi\) for \(G\) with \(v_1, v_2, v_3,\) and \(v_4\) identified. Since both \((1, 1, 1, 1)\) and \((1, 2, 3, 4)\) are Kirchhoff polynomials of graphs all monomials appear with nonnegative coefficients. Looking at [16] we see that the sign is 1 and the proof is complete.

5. Conclusions

Theorem 7 gives a nice generalization of [1]. Equation [1] itself is crucial to the combinatorial and algebro-geometric approach to understanding the periods of Feynman integrals [11, 2, 7, 6, 11]. In such work, having a good intuition of how to massage the polynomials which occur is crucial, and it is the second author’s experience that spanning forest polynomials and their identities are very useful in this regard.

We can ask for an edge-transferring interpretation of Theorem 7 comparable to what we discussed for [1] in the introduction. Consider [16], which is the result of setting the free variables to 0 in our main theorem. Collecting terms this gives
\[
(1, 2, 3, 4)(1, 1, 1, 1) = (1, 2, 3, 1)(1, -1, 1, 2) + (1, 2, 3, 2)(-1, 1, 1, 2) + (1, 2, 3, 3)(-1, -1, 1, 2)
\]
which says that we can choose to transfer an edge from any spanning forests contributing to \((1,1,1,1)\) to one of those contributing to \((1,2,3,4)\), so that we always merge the tree of the last vertex from \((1,2,3,4)\) into one of the other trees, and always split the last and second last vertices of \((1,1,1,1)\) into separate trees. Furthermore, the identity describes precisely how the split trees will interact with the remaining vertices. We know of no direct combinatorial proof which follows this interpretation.

We initially obtained \([3]\) by a numerical calculation. We first picked a graph on which to perform the calculations – we picked \(K_4\), \(K_5\) and \(K_6\). Then we calculated each \(A_i\) and \(B_i\) on this graph and then formed all possible products of \(A\)'s and \(B\)'s and formed the sum \(\sum_{s,t} x_{st} A_s B_t\), where \(x_{st}\) is a constant, \(1 \leq s \leq 6\) and \(1 \leq t \leq 7\) for a total of 42 constants, and solved the linear system. The initial numerical calculation could, a priori, have had spurious degrees of freedom, but it could not miss any true identity of the desired form. Consequently, \([3]\) is the most general quadratic formula involving 4 marked vertices.

A natural question is what do formulae for more marked vertices look like. Numerical calculations show that for 5 and 6 marked vertices the formulae have 15 and 24 free variables. For the classical Dodgson identity, the \(A\)'s and \(B\)'s are the same. If we treat the \(A\)'s and the \(B\)'s as different, we have a formula with 3 free variables. Trivially, a formula for 2 marked vertices has no free variables. For \(n = 2, 3, 4, 5\) and 6 the identities so far point to expressions having 0, 3, 8, 15 and 24 variables in formulae for \(n\) marked vertices. These numbers are generated by \(n(n-2)\) for \(n = 2, 3, 4, 5\) and 6.
