Outcomes of Stent Retriever versus Aspiration-First Thrombectomy in Ischemic Stroke: A Systematic Review and Meta-Analysis

C.O.A. Tsang, I.H.W. Cheung, K.K. Lau, W. Brinjikji, D.F. Kallmes, and T. Krings

ABSTRACT

BACKGROUND: There is ongoing debate regarding the optimal first-line thrombectomy technique for large-vessel occlusion.

PURPOSE: We performed a systematic review and meta-analysis of comparative studies on stent retriever–first and aspiration-first thrombectomy.

DATA SOURCES: We searched Ovid MEDLINE, PubMed, and EMBASE from 2009 to February 2018.

STUDY SELECTION: Two reviewers independently selected the studies. The primary end point was successful reperfusion (TICI 2b/3).

DATA ANALYSIS: Random-effects meta-analysis was used for analysis.

DATA SYNTHESIS: Eighteen studies including 2893 patients were included. There was no significant difference in the rate of final successful reperfusion (83.9% versus 83.3%; OR = 0.87; 95% CI, 0.62–1.27%) or good functional outcome (mRS 0–2) at 90 days (OR = 1.07; 95% CI, 0.80–1.44) between the stent-retriever thrombectomy and aspiration groups. The stent-retriever thrombectomy–first group achieved a statistically significant higher TICI 2b/3 rate after the first-line device than the aspiration-first group (74.9% versus 66.4%; OR = 1.53; 95% CI, 1.34–2.05%) and resulted in lower use of a rescue device (99.9% versus 32.5%; OR = 0.36; 95% CI, 0.14–0.90%). The aspiration-first approach resulted in a statistically shorter groin-to-reperfusion time (weighted mean difference, 7.15 minutes; 95% CI, 1.63–12.67 minutes). There was no difference in the number of passes, symptomatic intracerebral hemorrhage, vessel dissection or perforation, and mortality between groups.

LIMITATIONS: Most of the included studies were nonrandomized. There was significant heterogeneity in some of the outcome variables.

CONCLUSIONS: Stent-retriever thrombectomy–first and aspiration-first thrombectomy were associated with comparable final reperfusion rates and functional outcome. Stent-retriever thrombectomy was superior in achieving reperfusion as a stand-alone first-line technique, with lower use of rescue devices but a longer groin-to-reperfusion time.

ABBREVIATIONS: ADAPT = A Direct Aspiration, First Pass Technique for the Endovascular Treatment of Stroke; PRISMA = Preferred Reporting Items for Systematic Reviews and Meta-Analyses; RCT = randomized controlled trial; SRT = stent-retriever thrombectomy

Endovascular thrombectomy is recommended as a standard of care for anterior circulation acute ischemic stroke secondary to large-vessel occlusion.1 This treatment was established in 2015 when multiple randomized controlled trials (RCTs) established the clinical efficacy and safety of modern stent-retriever thrombectomy (SRT) in removing the obstructing thrombus in acute ischemia.2-6 A Direct Aspiration, First Pass Technique for the Endovascular Treatment of Stroke (ADAPT) is an alternative thrombectomy technique that has become the standard of care at many centers.7 This is performed by advancing a large-bore catheter (typically with an inner diameter of ≥0.060 inch) to the face of the thrombus, followed by its removal by aspiration alone or withdrawal of the catheter while aspirating. Previous observational studies focusing on ADAPT reported a higher rate of com-
plete revascularization and potentially a shorter time from groin puncture to reperfusion compared with stent-retriever thrombectomy. However, recent randomized trials comparing SRT with ADAPT have failed to demonstrate the superiority of ADAPT in technical or clinical outcomes. To address the ongoing debate of the optimal first-line thrombectomy technique, we performed a meta-analysis of comparative studies reporting outcomes on SRT versus ADAPT as a first-line approach.

MATERIALS AND METHODS

Search Strategy and Selection Criteria

A systematic literature review was performed following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The English literature was searched with Ovid MEDLINE, PubMed, and EMBASE from January 2009 to February 2018. The following terms and their combinations were used as keywords or Medical Subject Headings terms: “mechanical thrombectomy,” “endovascular,” “stroke,” “ADAPT,” “aspiration,” “stent retriever,” and “first-pass.” We also searched the references of relevant articles and contacted experts in the field to identify additional studies pertaining to the outcome of different thrombectomy techniques that were not included in the initial literature search.

Studies identified were then evaluated to meet the following inclusion criteria: 1) studies comparing the outcomes of the SRT-first and aspiration-first strategies; 2) studies reporting separately the clinical and technical outcomes of the SRT and aspiration groups; and 3) studies with at least 10 patients each in the SRT or aspiration group. The exclusion criteria were the following: 1) noncomparative studies reporting outcomes only on 1 group (SRT or aspiration); 2) studies that predominantly used the first generation of aspiration catheters (e.g., Penumbra Separator 0.041 [Penumbra, Alameda, California] or smaller catheters, with or without the Separator) in the aspiration arm; and 3) studies that did not separate outcomes by the first-line thrombectomy technique adopted. Both randomized and observational studies were included.

Data Items and Extraction

Patients were divided into 2 groups: SRT-first and aspiration-first. For this study, patients were considered to have SRT-first if any stent retriever was used in the first thrombectomy attempt, with or without balloon-guiding catheters or simultaneous distal aspiration (i.e., Solumbra technique). Those receiving only direct aspiration with large-bore distal-access catheters in the first thrombectomy attempt were considered aspiration-first.

The primary end point was the rate of successful reperfusion defined as the final Thrombolysis in Cerebral Infarction score of 2b/3. Other clinical outcomes included the following: good functional outcome defined as a modified Rankin Scale 0–2 at 90 days, 90-day mortality, symptomatic intracerebral hemorrhage, and complications of vessel dissection or perforation. Other technical outcomes studied included the following: the rate of complete reperfusion (TICI 3), the rate of TICI 2b/3 achieved with only the first device, the use of a rescue device, the number of thrombectomy passes, and the time from groin puncture to reperfusion.

Risk of Bias Assessment

The included studies were assessed for risk of bias by 2 independent readers (A.C.O.T. and I.H.W.C.) with the Newcastle Ottawa Scale. This is an 8-item tool for nonrandomized studies included in systematic reviews and meta-analyses, in which the selection, comparability, and ascertainment of outcomes of the study groups are assessed. The scale ranges from 0 to 9, with the higher score indicating lower risk of bias. Studies that used well-defined selection criteria, with comparable baseline stroke severity; patient demographics; onset-to-groin puncture time, with contemporaneous use of SRT; and aspiration thrombectomy and those that had an independent assessment of clinical and technical outcomes are considered to have a low risk of bias.

Statistical Analysis

We extracted from each study a 2 × 2 table for binary outcomes and the mean group sample size and a variability measure for continuous outcomes. The pooled outcomes were meta-analyzed using a random-effects model. Heterogeneity of the studies not attributable to chance was quantified with the I² statistic. The 95% confidence intervals of the odds ratios for binary outcomes and the weighted mean differences for continuous outcomes were reported. Some included studies reported continuous outcomes with median and interquartile range; these were converted to a mean and SD value based on the assumption of a log-normal distribution of the original measure. When the SD or the interquartile range for a specific outcome was not reported in the article, it was extrapolated from other studies when such data were available. If >10 studies were identified, a funnel plot was constructed to explore the impact of publication bias.

Only 3 of the 18 included studies were randomized by the first thrombectomy strategy. To address the potential heterogeneity between the 2 study groups, we conducted meta-regression to test the influence of moderators, including baseline stroke severity measured by the National Institutes of Health Stroke Scale and age. Sensitivity analyses were performed by studying the comparative outcomes, including only those studies that were RCTs, those that included predominantly (>90%) anterior circulation thrombectomy, and those that used balloon-guiding catheters with SRT consistently. Meta-analysis and meta-regression were performed with OpenMeta[Analyst] (http://www.cebm.brown.edu/openmeta/).

RESULTS

Literature Search

The initial literature search yielded 862 articles. The titles and abstracts of these were read, and 818 articles were excluded for irrelevance. Of the remaining 44 articles, 14 were excluded because they were conference abstracts, and 7 were excluded because they were review articles or editorials. After review, 2 articles were excluded for overlapping patient populations, and 4 studies were excluded for predominantly using a previous generation of thrombectomy devices. One additional study was identified by contacting experts in the field, yielding a total of 18 studies eligible for analysis. The PRISMA flow diagram is provided in Fig 1.
Clinical Outcomes

There was no statistical difference in the rate of good functional outcome (mRS 0–2) at 90 days between groups (OR = 1.07; 95% CI, 0.80–1.44). There was also no significant difference in the mortality rate, the rate of symptomatic intracerebral hemorrhage, emboli to new territories, vessel dissection, or perforation between the 2 groups. These results are summarized in Tables 2 and 3.

Publication Bias and Study Heterogeneity

Funnel plot analysis did not suggest publication bias (Fig 3). There was low heterogeneity ($I^2 < 50\%$) for the following outcomes: the TICI 2b/3 rate after the first-line approach ($I^2 = 31\%$), mortality rate ($I^2 = 28\%$), risk of symptomatic intracerebral hemorrhage ($I^2 = 0\%$), emboli to new territories ($I^2 = 0\%$), and vessel dissection or perforation ($I^2 = 26\%$). There was moderate substantial heterogeneity ($I^2 >50\%$) for the following outcomes: final rate of TICI 2b/3 ($I^2 = 54\%$), final rate of TICI 3 ($I^2 = 79.5\%$), mRS 0–2 at 90 days ($I^2 = 62\%$), the need for a rescue device ($I^2 = 93\%$), groin-to-reperfusion time ($I^2 = 79\%$), and the number of passes required ($I^2 = 77\%$).

Meta-regression analyses performed on outcomes with high heterogeneity (final TICI 2b/3 and mRS 0–2 at 90 days) did not identify variables explaining differences between studies.

Sensitivity Analysis

We performed a subgroup analysis to determine whether the outcomes were different in anterior circulation stroke versus posterior circulation stroke. In the 9 studies that included predominantly (>90\%) anterior circulation stroke, there was no statistically significant difference in the final TICI 2b/3 rate between groups (OR = 0.892; 95% CI, 0.59–1.35). Four studies reporting posterior circulation stroke only were included. The use of the SRT-first approach in posterior circulation stroke was associated with a statistically significant lower successful reperfusion (OR = 0.47; 95% CI, 0.25–0.91).

When we included only the 3 randomized controlled trials, we found no difference in the final TICI 2b/3 rate (OR = 1.05; 95% CI, 0.58–1.90) and good functional outcome (OR = 1.04; 95% CI, 0.79–1.37). There was a non-statistically significant higher chance in the SRT-first group of achieving TICI 2b/3 after the first-line approach (OR = 1.26; 95% CI, 0.85–1.86).

When including only the 5 studies that consistently used balloon-guiding catheters with SRT, we again found no difference in the final TICI 2b/3 rate (OR = 0.95; 95% CI, 0.54–1.67) and good functional outcome (OR = 1.22; 95% CI, 0.91–1.64). There was a non-statistically significant higher chance in the SRT-first group of achieving TICI 2b/3 after the first-line approach (OR = 1.26; 95% CI, 0.92–1.73).

When we excluded the study that used the Penumbra 3D Separator device, which was different in design from other conventional stent retrievers, there were no differences in the final TICI 2b/3 rate (OR = 0.88; 95% CI, 0.62–1.25). When we included only the 3 studies that reported TICI 2c/3 outcomes, there were no differences in the final TICI 2c/3 rate (OR = 1.10; 95% CI, 0.61–1.89) between groups.
DISCUSSION

Our meta-analysis of 2893 patients from 18 studies found no significant difference in terms of the final revascularization rate and functional outcome between aspiration-first and SRT-first thrombectomy for large-vessel occlusion stroke. Notably, stent retriever use was superior in achieving successful reperfusion as a stand-alone technique, compared with aspiration. The need for a rescue device was also significantly less when SRT was adopted as a first approach instead of aspiration. The comparable final reperfusion rate in the aspiration group was achieved with the use of a rescue device after the initial failed attempts with contact aspiration, which was necessary in 32.5% of patients. These findings are important because they suggest that despite SRT and aspiration-first strategies being able to achieve similar final revascularization rates and functional outcomes, SRT appears to be more effective than aspiration as a primary treatment technique for achieving TICI 2b/3 revascularization.

Endovascular thrombectomy with stent retrievers for large-vessel occlusion stroke has been established as the standard of care since 2015. The use of direct-contact aspiration thrombectomy

Note:—NOS indicates Newcastle-Ottawa Scale; NA, not available; Asp, aspiration.

FIG 2. Forest plot of meta-analysis results. A, Final successful reperfusion was TICI 2b/3. B, Good functional outcome mRS 0–2 at 90 days. Successful reperfusion TICI 2b/3 after the first-line approach (C) and the use of a rescue device (D).

Table 2: Summary of meta-analysis outcomes

| Outcome                          | Odds Ratio 95% CI | I² |
|----------------------------------|------------------|----|
| Final TICI 2b/3                   | 0.87 (0.62–1.27) | 53.6% |
| Final TICI 3                      | 0.82 (0.49–1.37) | 79.5% |
| First-line approach, TICI 2b/3   | 1.53 (1.14–2.05) | 31.1% |
| mRS 0–2 at 90 days               | 1.07 (0.80–1.44) | 61.8% |
| Mortality                        | 0.91 (0.69–1.20) | 28.1% |
| Rescue device                    | 0.36 (0.14–0.90) | 93.0% |
| Dissection or perforation        | 1.26 (0.52–3.18) | 26.3% |
| ENT                              | 1.11 (0.70–1.74) | 0%   |
| sICH                             | 1.20 (0.78–1.84) | 0%   |

Note:—ENT indicates emboli to new territories; sICH, symptomatic intracranial hemorrhage.

Table 3: Summary of meta-analysis outcomes

| Weighted Mean Difference 95% CI | I² |
|----------------------------------|----|
| Groin to perfusion (min)         | 7.15 (6.21–8.10) | 79.0% |
| No. of passes                    | 0.06 (−0.40–0.52) | 77.0% |
is another common technique but was not supported by class I evidence. Nevertheless, aspiration thrombectomy as a first-line approach is widely practiced in the United States, Hong Kong, and Italy despite the availability of the proved and efficacious stent-retriever thrombectomy.33–35 The THERAPY (The Randomized, Concurrent Controlled Trial to Assess the Penumbra System’s Safety and Effectiveness in the Treatment of Acute Stroke; NCT01429350) trial, which compared aspiration thrombectomy with best medical therapy, was halted early and did not demonstrate efficacy.36 While recent meta-analyses of uncontrolled observational studies focusing solely on the aspiration technique reported higher complete reperfusion rates and shorter procedure times than SRT,37–38 these conclusions were confounded by the different patient-selection criteria and baseline stroke severity in the included single-arm studies. The published RCTs on this subject demonstrated noninferiority of aspiration thrombectomy compared with SRT in the final reperfusion rate but were underpowered to compare other clinical outcomes such as functional status and complication rates.39,40 To address these limitations, the present review included only studies that compared both SRT-first and aspiration-first approaches in the same patient cohort, as well as the 3 recently published/presented RCTs investigating these 2 groups.

One of the notable findings from our study is that SRT could achieve higher rates of TICI 2b/3 reperfusion without the help of rescue therapy than aspiration thrombectomy alone. This is important because the literature has focused more on the first-pass effect during thrombectomy for acute ischemic stroke, defined as achieving complete recanalization with a single pass. In a recently published post hoc analysis of the North American Solitaire Acute Stroke Registry, Zaidat et al.38 found that patients who achieved TICI 2b/3 on a first pass had significantly better clinical outcomes than those who did not. Independent predictors of a first-pass effect included the use of a balloon-guiding catheter and nonin-ternal carotid artery terminus occlusion. While we were not able to examine first-pass recanalization rates between SRT and aspiration in this meta-analysis, SRT alone achieved higher recanalization rates than aspiration alone. Ultimately, the fact that SRT aspiration over SRT is the shorter procedural time. The aspiration-first approach was associated with a 7-minute advantage in groin-to-reperfusion time in the meta-analysis. In the 3 randomized studies comparing the 2 approaches, the aspiration-first approach also resulted in a shorter procedural time of 10–13 minutes.9,27,28 Nevertheless, this advantage in rapidity did not translate to improved patient outcome in any of those trials.

While the overall final reperfusion rate is comparable, there remain uncertainties about whether SRT or aspiration is superior in selected vessel locations or the etiology of stroke. Subgroup analysis of the 4 posterior circulation stroke studies including 264 patients showed that SRT was inferior to aspiration in terms of reperfusion rates. However, the sample size was too small to draw any definitive conclusions. None of the included studies reported the comparative efficacy of aspiration and SRT stratified by the specific occluded vessel to allow subgroup analysis. The etiology of large-vessel occlusion may also affect the efficacy of thrombec- tomy. In large-vessel occlusion secondary to intracranial artery stenosis, early experience with stent retrievers in this group of patients resulted in a lower reperfusion rate and poorer outcome. In addition, rescue therapy with balloon angioplasty or intra-arterial thrombolytic infusion was frequently required.40 The shearing force exerted over the atherosclerotic plaque during stent retrieval may be the culprit, and the optimal first-line thrombec- tomy strategy in this group of patients needs further investigation. Techniques combining SRT and aspiration have been increasingly used, but their superiority over SRT or aspiration alone remains to be defined in randomized studies.17,41,42 Future studies on the optimal thrombectomy technique should also adopt more robust outcome variables, including TICI 2c/3 angiographic outcome and the first-pass success rate,38,43 and should consider other aspects such as delayed effects on the vessel wall and the relative cost-effectiveness of different techniques.

Limitations
Our study has limitations. Apart from the 3 RCTs, most of the included studies were nonrandomized, thus introducing selection
bias. When performing subgroup analysis on only the 3 recent RCTs, we found results similar to those in our meta-analysis. We limited the review to comparative studies with control groups to compare the relative efficacy of SRT and aspiration and excluded those studies that used predominantly previous generations of thrombectomy catheters or devices. There was significant statistical heterogeneity in some of the outcome variables that can impact the validity of our results. Another limitation is that in some cases SRT was performed with simultaneous aspiration (ie, Solumbra technique) and we could not perform subgroup analyses of Solumbra versus SRT-alone versus aspiration. While TICI 2c/3 is increasingly recognized as a better angiographic outcome measure and correlates better with clinical outcome, only 3 of the included studies reported TICI 2c/3 rates and the subgroup analysis on these studies showed similar results.

CONCLUSIONS
This systematic review and meta-analysis of 18 studies and 2893 patients found that SRT-first and aspiration-first thrombectomy were associated with comparable final reperfusion rates and functional outcomes. SRT was superior in achieving reperfusion as a stand-alone first-line technique, with lower use of rescue devices but a longer groin-to-reperfusion time. There were no significant differences in complication rates and mortality. The optimal first-line thrombectomy approach for specific location or stroke etiology remains unclear.
