NONCOMMUTATIVE QUADRIC SURFACES AND NONCOMMUTATIVE CONIFOLDS

SHINNOSUKE OKAWA, KAZUSHI UEDA

To the memory of Kentaro Nagao

Abstract. We introduce a compact moduli of noncommutative quadrics, and show that it is the weighted projective space of weight (2,4,4,6). We also introduce a compact moduli of potentials for the conifold quiver, and show that it is the weighted projective space of weight (1,2,3,4). There is a natural morphism from the latter to the former, which is finite of degree 4.

1. Introduction

The conifold is an ordinary double point in dimension 3. It is a cone over \( \mathbb{P}^1 \times \mathbb{P}^1 \) from the complex point of view, and a cone over \( S^2 \times S^3 \) from the real point of view. It is the most basic singularity in dimension 3, which appears in various areas of geometry and physics, such as Reid’s fantasy [Fri86, Rei87], conifold transition [BCFKvS98], Sasaki-Einstein geometry [Tan79], knot theory [OV00], and AdS/CFT correspondence [KW99].

As a cone over \( \mathbb{P}^1 \times \mathbb{P}^1 \), the conifold \( X \) is obtained by contracting the zero-section of the total space \( \tilde{Y} = \text{Spec}_{\mathbb{P}^1 \times \mathbb{P}^1} \left( \bigoplus_{n=0}^{\infty} \mathcal{O}_{\mathbb{P}^1 \times \mathbb{P}^1}(1,1)^{\otimes n} \right) \) of a line bundle on \( \mathbb{P}^1 \times \mathbb{P}^1 \). The contractions along two rulings of \( \mathbb{P}^1 \times \mathbb{P}^1 \) give two crepant resolutions of the conifold;

\[
\begin{array}{ccc}
\tilde{Y} & \overset{\sim}{\longrightarrow} & Y^\dagger \\
\downarrow & & \downarrow \\
Y & & Y^\dagger \\
\downarrow & & \downarrow \\
X & & X
\end{array}
\]

Both \( Y \) and \( Y^\dagger \) are isomorphic to \( \text{Spec}_{\mathbb{P}^1} \left( \text{Sym}^* (\mathcal{O}_{\mathbb{P}^1}(1) \oplus \mathcal{O}_{\mathbb{P}^1}(1)) \right) \). The birational morphism \( Y \rightarrow Y^\dagger \) obtained from the above diagram, known as the Atiyah flop [Ati58], is responsible for the non-separatedness of the moduli space of K3 surfaces.

Besides two crepant resolutions, the conifold has a noncommutative crepant resolution [VdB04a, VdB04b]. It is an algebra \( A_0 \) of the form \( \text{End}_{R_0} M \), where \( R_0 = \mathbb{C}[x,y,z,w]/(xy - zw) \) is the coordinate ring of \( X \), and \( M = R_0 \oplus I, I = (x,z) \subset R_0 \), is a reflexive \( R_0 \)-module. All these crepant resolutions are derived-equivalent [BO, Bri02, VdB04b];

\[
D(\text{Qcoh} \, Y) \cong D(\text{Mod} \, A_0) \cong D(\text{Qcoh} \, Y^\dagger).
\]

The algebra \( A_0 \) can be described as the Jacobi algebra \( \mathbb{C}Q/(\partial \Phi_0) \) of the quiver in Figure 1.1 with the potential

\[
\Phi_0 = a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1.
\]
Szendrői [Sze08] introduced the notion of noncommutative Donaldson invariant, and conjectured that its generating function
\[ Z(q) = \sum_{v \in \mathbb{Z}^2} D(v)q^v, \quad D(v) = \sum_{n \in \mathbb{Z}} n\chi(n^{-1}(n)), \]
has an infinite product expansion
\[ Z(q) = Z_{DT}(Y; q_0 q_1, q_1^{-1}) \prod_{m=1}^{\infty} \left(1 + q_0^m (-q_1)^{m+1}ight)^m. \]

Here \( \nu : \mathcal{M}(v) \to \mathbb{Z} \) is the Behrend function [Beh09] on the moduli space \( \mathcal{M}(v) \) of cyclic \( \tilde{A} \)-modules of dimension vector \( (v_0, v_1, 1) \), and \( Z_{DT}(Y; q_0 q_1, q_1^{-1}) \) is the Donaldson-Thomas invariant [DT98, Tho00, MNOP06, MNOP06] of the resolved conifold \( Y \). Szendrői’s conjecture is proved by Young [You09] in a combinatorial way, and by Nagao and Nakajima [NN11] in an algebro-geometric way. This result is generalized to small toric Calabi-Yau 3-folds in [Nag12, You10], and to motivic invariants in [MMNS12, MN].

In this paper, we consider deformations of the algebra \( A_0 \) as a graded Calabi-Yau algebra of dimension 3. Since any graded Calabi-Yau algebra of dimension 3 comes from a quiver with potential [Boc08, Theorem 3.1], we study deformation of potentials instead of deformation of algebras. The potential of the conifold quiver in Figure 1.1 is an element of \( \text{Sym}^2(V_0 \otimes V_1) \), where \( V_0 \) and \( V_1 \) are two-dimensional vector spaces, and two potentials give isomorphic graded algebras if they are related by the action of \( GL(V_0) \times GL(V_1) \). This motivates us to define the moduli stack of potentials as
\[ \mathcal{M}_{\text{pot}} = \left[ \text{Sym}^2(V_0 \otimes V_1) / GL(V_0) \times GL(V_1) \right]. \]
The corresponding compact moduli scheme, obtained as the GIT quotient, will be denoted by
\[ \overline{\mathcal{M}}_{\text{pot}} = \text{Proj} \left( \mathbb{C} \left[ \text{Sym}^2(V_0 \otimes V_1) \right]^{SL(V_0) \times SL(V_1)} \right). \]

The double cover of the conifold quiver shown in Figure 1.2 inherits the potential from the conifold quiver. When the potential for the conifold quiver is the classical one in (1.2), then the
of two copies of certain elliptic surface over the modular curve; as for quadruples, we give a birational parametrization in terms of a quotient of the fiber product.

Theorem 1.1. The main result in this paper is the following:

(1.8) \[ \mathcal{M}_{\text{qui}} = \text{Proj} \left( \mathcal{C} \left[ V_0 \otimes V_1 \otimes V_2 \otimes V_3 \right]^{SL(V_0) \times SL(V_1) \times SL(V_2) \times SL(V_3)} \right). \]

As for quadruples, we give a birational parametrization in terms of a quotient of the fiber product of two copies of certain elliptic surface over the modular curve;

(1.9) \[ \mathcal{M}_{\text{quad}} = S(2) \times X(2) S(2)/ (SL_2(\mathbb{F}_2) \times (\mathbb{Z}/2\mathbb{Z})^4). \]

The main result in this paper is the following:

**Theorem 1.1.**

1. The moduli stack \( \mathcal{M}_{\text{qui}} \), after removing the generic stabilizer group \( G_m^4 \), is birational to the GIT quotient \( \overline{\mathcal{M}}_{\text{qui}} \). This in turn is isomorphic to the weighted projective space \( \mathbb{P}(2, 4, 4, 6) \).
2. The moduli spaces \( \mathcal{M}_{\text{qui}} \) and \( \overline{\mathcal{M}}_{\text{quad}} \) are birational.
3. The moduli stack \( \mathcal{M}_{\text{pot}} \), after removing the generic stabilizer group \( G_m \), is birational to the GIT quotient \( \overline{\mathcal{M}}_{\text{pot}} \). This in turn is isomorphic to the weighted projective space \( \mathbb{P}(1, 2, 3, 4) \).
4. There is a natural morphism \( \mathcal{M}_{\text{pot}} \to \mathcal{M}_{\text{qui}} \), which induces a finite morphism \( \overline{\mathcal{M}}_{\text{pot}} \to \overline{\mathcal{M}}_{\text{qui}} \) of degree 4.

The moduli space \( \mathcal{M}_{\text{qui}} \) also appears in [OU] as the moduli space of 4-qubit states. Theorem 1.1 (1) is a consequence of known results [LT03, Wal08], and has little claim in originality.

This paper is organized as follows: In Section 2 we summarize results from [VdB11] on noncommutative quadric surfaces. Theorem 1.1 (1) is proved in Section 3 and Theorem 1.1 (2) is proved in Section 4. The proofs of Theorems 1.1 (3) and 1.1 (4) are given in Section 5. In Section 6, we introduce the notion of noncommutative conifolds, and discuss their relation with potentials. In Section 7, we show that the motivic Donaldson-Thomas invariants depend on the potential.

Acknowledgment. S. O. is supported by JSPS Grant-in-Aid for Young Scientists No. 25800017. K. U. is supported by JSPS Grant-in-Aid for Young Scientists No. 24740043. A part of this work is done while K. U. is visiting Korea Institute for Advanced Study, whose hospitality and nice working environment is gratefully acknowledged.
2. Noncommutative quadric surfaces

See [VdB11, Section 2] for more details of the contents of this section. A \( \mathbb{Z} \)-algebra is an algebra with a direct sum decomposition

\[
A = \bigoplus_{i,j \in \mathbb{Z}} A_{ij}
\]

such that the product satisfies

\[
\begin{align*}
A_{ij}A_{kl} &= 0 \text{ for } j \neq k, \text{ and } \\
A_{ij}A_{jk} &\subset A_{ik}.
\end{align*}
\]

We assume that \( A_{ii} \) for any \( i \in \mathbb{Z} \) has an element \( e_i \), called the local unit, which satisfies

\[
\begin{align*}
fe_i &= f \text{ for any } f \in A_{ki}, \text{ and } \\
e_i g &= g \text{ for any } g \in A_{ij}.
\end{align*}
\]

A \( \mathbb{Z} \)-algebra \( A \) is positively graded if \( A_{ij} = 0 \) for \( i > j \).

A positively graded \( \mathbb{Z} \)-algebra \( A \) is connected if \( \dim A_{ij} < \infty \) and \( A_{ii} = \mathbb{C}e_i \) for any \( i, j \in \mathbb{Z} \).

A graded \( A \)-module is a right \( A \)-module of the form \( M = \bigoplus_{i \in \mathbb{Z}} M_i \) such that

\[
\begin{align*}
M_iA_{kl} &= 0 \text{ for } i \neq k, \text{ and } \\
M_iA_{ij} &\subset M_j.
\end{align*}
\]

A connected \( \mathbb{Z} \)-algebra \( A \) is AS-regular if \( \dim A_{ij} \) is bounded by a polynomial in \( j - i \), and

\[
\sum_{j,k} \dim \text{Ext}^j_{\text{Gr } A}(S_k, P_i) = 1 \text{ for any } i \in \mathbb{Z},
\]

where \( P_i = e_iA \) is a projective \( A \)-module, and \( S_i = \mathbb{C}e_i \) is a simple \( A \)-module. An AS-regular \( \mathbb{Z} \)-algebra \( A \) is a 3-dimensional cubic AS-regular \( \mathbb{Z} \)-algebra if the minimal resolution of \( S_i \) is of the form

\[
0 \to P_{i+4} \to P_{i+3}^2 \to P_{i+1}^2 \to P_i \to S_i \to 0.
\]

A graded \( A \)-module \( M \) is positively bounded if \( M_i = 0 \) for sufficiently large \( i \). A graded \( A \)-module is a torsion module if it can be described as the colimit of a sequence of positively bounded \( A \)-modules. The quotient abelian category of the abelian category \( \text{Gr } A \) of graded \( A \)-modules by the Serre subcategory \( \text{Tor } A \) consisting of torsion modules will be denoted by

\[
\text{Qgr } A = \text{Gr } A / \text{Tor } A.
\]

A noncommutative quadric surface is an abelian category of the form \( \text{Qgr } A \) for a 3-dimensional cubic AS-regular \( \mathbb{Z} \)-algebra [VdB11, Definition 3.2].

A 3-dimensional cubic AS-regular \( \mathbb{Z} \)-algebra is linear if it is of the form

\[
A = \bigoplus_{i,j \in \mathbb{Z}} \text{Hom}(\mathcal{O}_{\mathbb{P}^1 \times \mathbb{P}^1}(-j), \mathcal{O}_{\mathbb{P}^1 \times \mathbb{P}^1}(-i))
\]
where

\begin{equation}
O_{\mathbb{P}^1 \times \mathbb{P}^1}(n) = \begin{cases} 
O_{\mathbb{P}^1}(k) \boxtimes O_{\mathbb{P}^1}(k) & n = 2k, \\
O_{\mathbb{P}^1}(k) \boxtimes O_{\mathbb{P}^1}(k+1) & n = 2k + 1.
\end{cases}
\end{equation}

All other 3-dimensional cubic AS-regular Z-algebra will be called elliptic.

A quintuple \((V_0, V_1, V_2, V_3, W)\) consists of

\begin{equation}
\text{(2.17)}
\end{equation}

two-dimensional vector spaces \(V_0, V_1, V_2, V_3\), and

\begin{equation}
\text{(2.18)}
a one-dimensional subspace \(W\) of \(V_0 \otimes V_1 \otimes V_2 \otimes V_3\).
\end{equation}

A quintuple is geometric if a basis \(w\) of \(W\) satisfies

\begin{equation}
\text{(2.19)}
\langle \phi_j \otimes \phi_{j+1}, w \rangle \neq 0 \in V_{j+2} \otimes V_{j+3}
\end{equation}

for any \(j = 0, 1, 2, 3\) and any non-zero \(\phi_j \in V_j^\vee\), \(\phi_{j+1} \in V_{j+1}^\vee\), where indices are taken modulo 4 [VdB11, Definition 4.7]. A geometric quintuple is linear if it can be written as

\begin{equation}
\text{(2.20)}
w = x_0 x_1 y_2 y_3 - y_0 x_1 x_2 y_3 - x_0 y_1 y_2 x_3 + y_0 y_1 x_2 x_3
\end{equation}

for a suitable choice of a basis \(\{x_i, y_i\}\) of \(V_i\) for \(i = 0, 1, 2, 3\) (see [VdB11, Lemma 4.6]). All other geometric quintuples are called elliptic. Two quintuples \((V_0, V_1, V_2, V_3, W)\) and \((V'_0, V'_1, V'_2, V'_3, W')\) are isomorphic if there are linear isomorphisms \(V_i \cong V'_i\) for \(i = 0, 1, 2, 3\) sending \(W \subset V_0 \otimes V_1 \otimes V_2 \otimes V_3\) to \(W' \subset V'_0 \otimes V'_1 \otimes V'_2 \otimes V'_3\).

A globally generated line bundle \(\mathcal{L}\) on a scheme \(C\) defines a morphism \(\phi_{\mathcal{L}} : C \to \mathbb{P}(H^0(\mathcal{L})^\vee)\), whose direct product will be denoted by

\begin{equation}
\phi_{\mathcal{L},\mathcal{L'} : C \to \mathbb{P}(H^0(\mathcal{L})^\vee) \times \mathbb{P}(H^0(\mathcal{L'})^\vee).
\end{equation}

An admissible quadruple \((C, \mathcal{L}_0, \mathcal{L}_1, \mathcal{L}_2)\) consists of a curve \(C\) and line bundles \(\mathcal{L}_0, \mathcal{L}_1, \mathcal{L}_2\) on \(C\) of degree 2 such that

\begin{equation}
\text{(2.22)}
h^0(\mathcal{L}_i) = 2 \text{ for } i = 0, 1, 2,
\end{equation}

\begin{equation}
\text{(2.23)}
C \text{ is embedded as a divisor of bidegree (2, 2) in } \mathbb{P}^1 \times \mathbb{P}^1 \text{ by both } \phi_{\mathcal{L}_0,\mathcal{L}_1} \text{ and } \phi_{\mathcal{L}_1,\mathcal{L}_2},
\end{equation}

\begin{equation}
\text{(2.24)}
\deg(\mathcal{L}_0|_E) = \deg(\mathcal{L}_2|_E) \text{ for every irreducible component } E \text{ of } C, \text{ and}
\end{equation}

\begin{equation}
\text{(2.25)}
\mathcal{L}_0 \neq \mathcal{L}_2.
\end{equation}

Two admissible quadruples \((C, \mathcal{L}_0, \mathcal{L}_1, \mathcal{L}_2)\) and \((C', \mathcal{L}'_0, \mathcal{L}'_1, \mathcal{L}'_2)\) are isomorphic if there is an isomorphism \(\varphi : C \to C'\) of curves such that \(\varphi^* \mathcal{L}'_i \cong \mathcal{L}_i\) for \(i = 0, 1, 2\).

There is a bijective correspondence among isomorphisms classes of

\begin{equation}
\text{(2.26)} \text{ elliptic 3-dimensional cubic AS-regular Z-algebras,}
\end{equation}

\begin{equation}
\text{(2.27)} \text{ elliptic quintuples, and}
\end{equation}

\begin{equation}
\text{(2.28)} \text{ admissible quadruples,}
\end{equation}

given as follows:

- [VdB11] §4.2 : For a 3-dimensional cubic AS-regular Z-algebra \(A = \bigoplus_{i \leq j} A_{ij}\), set \(V_i = A_{i,i+1}\) for \(i = 0, 1, 2, 3\) and \(R_i = \ker(V_i \otimes V_{i+1} \otimes V_{i+2} \to A_{i,i+3})\) for \(i = 0, 1, 2\). Then \(W_0 = R_0 \otimes V_3 \cap V_0 \otimes R_1\) is one-dimensional, and \((V_0, V_1, V_2, V_3, W_0)\) gives a geometric quintuple.

- [VdB11] §4.4 : For a geometric quintuple \(Q = (V_0, V_1, V_2, V_3, W_0 = k w)\), choose bases \(\{x_i, y_i\}\) of \(V_i\) and write \(w = fx_3 + gy_3\). Let \(C \subset \mathbb{P}(V_0) \times \mathbb{P}(V_1) \times \mathbb{P}(V_2)\) be the variety defined by the equations \(\{f, g\}\), and set \(\mathcal{L}_i = p_i^*(O(1))\) for \(i = 0, 1, 2\), where \(p_i : C \to \mathbb{P}(V_i)\) are the
projections. The geometricity of \( Q \) implies that \( \phi_{\mathcal{Z}_0, \mathcal{Z}_1} = (p_0, p_1) \) and \( \phi_{\mathcal{Z}_1, \mathcal{Z}_2} = (p_1, p_2) \) are closed embeddings, and one obtains a quadruple \((C, \mathcal{L}_0, \mathcal{L}_1, \mathcal{L}_2)\).

- \([\text{VdB11}, \S 4.5]\) : For an admissible quadruple \((C, \mathcal{L}_0, \mathcal{L}_1, \mathcal{L}_2)\), construct a helix \((\mathcal{L})_{i \in \mathbb{Z}}\) by

\[
\mathcal{L}_i \otimes \mathcal{L}_{i+1} \otimes \mathcal{L}_{i+2} \otimes \mathcal{L}_{i+3} = 0_C.
\]

Then the \( \mathbb{Z} \)-algebra generated by \( A_{i,i+1} = V_i = H^0(C, \mathcal{L}_i) \) with the relations \( R_i = \ker(V_i \otimes V_{i+1} \otimes V_{i+2} \to A_{i,i+3}) \) is an elliptic 3-dimensional cubic AS-regular \( \mathbb{Z} \)-algebra.

3. Moduli of Quintuples

The invariant ring of \( \mathbb{C}[V_0 \otimes V_1 \otimes V_2 \otimes V_3] \) with respect to the action of \( SL(V_0) \times SL(V_1) \times SL(V_2) \times SL(V_3) \) is given in [LT03]. In this section, we give a description of this invariant ring along the lines of [VDDMV02, Wal08] and prove Theorem [\text{VdB11}].

Let

\[
\omega(x_1e_1 + x_2e_2, y_1e_1 + y_2e_2) = x_1y_2 - x_2y_1
\]

be a skew-symmetric bilinear form on \( \mathbb{C}^2 \). The action of \( SL_2(\mathbb{C}) \times SL_2(\mathbb{C}) \) on \( \mathbb{C}^2 \otimes \mathbb{C}^2 \) defined by

\[
(g, h) \cdot u \otimes v = (gu) \otimes (hv).
\]

preserves the non-degenerate symmetric bilinear form

\[
(v \otimes w, x \otimes y) = \omega(v, x)\omega(w, y),
\]

whose Gram matrix with respect to the basis \( \{e_1 \otimes e_1, e_1 \otimes e_2, e_2 \otimes e_1, e_2 \otimes e_2\} \) is given by

\[
J = \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0 \\
0 & -1 & 0 & 0 \\
1 & 0 & 0 & 0
\end{pmatrix}.
\]

An orthonormal basis with respect to \( J \) is given by

\[
T := \frac{1}{\sqrt{2}} \begin{pmatrix}
1 & 0 & 0 & 1 \\
0 & \sqrt{-1} & 0 & \sqrt{-1} \\
0 & -1 & 1 & 0 \\
\sqrt{-1} & 0 & 0 & -\sqrt{-1}
\end{pmatrix},
\]

so that one obtains a homomorphism

\[
\varphi : SL_2(\mathbb{C}) \times SL_2(\mathbb{C}) \rightarrow SO_4(\mathbb{C})
\]

\(\Psi\)

\[ (g_1, g_2) \mapsto T^T(g_1 \otimes g_2)T \]

of algebraic groups. The induced morphism

\[
(d\varphi)_e : sl_2(\mathbb{C}) \oplus sl_2(\mathbb{C}) \rightarrow so(\mathbb{C})
\]

of Lie algebras is an isomorphism called the accidental isomorphism. Hence the morphism \( \varphi \) is étale surjective, and one can easily see that

\[
\text{Ker } \varphi = \{ \pm (I, I) \} \in SL_2(\mathbb{C}) \times SL_2(\mathbb{C}).
\]

One can identify the ring \( \mathbb{C}[V_0 \otimes V_1 \otimes V_2 \otimes V_3] \) with the ring \( \mathbb{C}[U \otimes U'] \) equipped with the action of \( SO(U) \times SO(U') \) through the homomorphisms \( SL(V_0) \times SL(V_1) \rightarrow SO(U) \) and \( SL(V_2) \times SL(V_3) \rightarrow SO(U') \), in such a way that the invariant rings are isomorphic;

\[
\mathbb{C}[V_0 \otimes V_1 \otimes V_2 \otimes V_3]^{SL(V_0) \times SL(V_1)\times SL(V_2)\times SL(V_3)} \cong \mathbb{C}[U \otimes U']^{SO(U)\times SO(U')}.\]
The action of $SO(U) \times SO(U')$ on $U \otimes U'$ can be identified with the action of $SO(U) \times SO(U)$ on $\text{End} U$ given by
\[(g, h) \cdot X = gXh^T.\]

Singular value decomposition allows us to turn any $n \times n$ matrix into a diagonal matrix under this action. The entries $x_1, \ldots, x_n$ of the resulting diagonal matrix is unique up to
- permutations of $x_1, \ldots, x_n$, and
- sign changes $x_i \mapsto \epsilon_i x_i$, where $\epsilon_i = \pm 1$ and $\epsilon_1 \cdots \epsilon_n = 1$.

As a consequence, one has an isomorphism
\[(3.11) \quad \mathbb{C}[\text{End} U]^{SO(U) \times SO(U)} \cong \mathbb{C}[x_1, x_2, x_3, x_4]^W \]
\[(3.12) \quad = \mathbb{C}[f_2, f_4, g_4, f_6],\]
where $W = S_4 \rtimes (\mathbb{Z}/2\mathbb{Z})^3$ acts on $\mathbb{C}^4$ by permutations and sign changes, and
\[(3.13) \quad f_{2d} = \sum_{i=1}^{4} x_i^{2d},\]
\[(3.14) \quad g_4 = x_1 x_2 x_3 x_4.\]

The corresponding elements of $\mathbb{C}[\text{End} U]^{SO(U) \times SO(U)}$ are
\[(3.15) \quad f_{2d}(X) = \text{Tr} ((X^TX)^d),\]
\[(3.16) \quad g_4 = \text{det}(X).\]

It follows that
\[(3.17) \quad \text{an element } X \in \text{End} U \text{ is stable if and only if } g_4(X) \neq 0,\]
\[(3.18) \quad \text{an element } X \in \text{End} U \text{ is unstable if and only if } X^TX \text{ is nilpotent, and}\]
\[(3.19) \quad \text{the GIT quotient is given by } \text{Proj} \mathbb{C}[f_2, f_4, g_4, f_6] = \mathbb{P}(2, 4, 4, 6).\]

4. Elliptic quadruples

The principal congruence subgroup
\[(4.1) \quad \Gamma(2) = \text{Ker}(SL_2(\mathbb{Z}) \rightarrow SL_2(\mathbb{F}_2))\]
of the modular group $SL_2(\mathbb{Z})$ acts on the upper half plane $\mathbb{H}$ by
\[(4.2) \quad \left(\begin{array}{cc} a & b \\ c & d \end{array}\right), \tau \mapsto a\tau + b/c\tau + d.\]

The generic stabilizer of this action is $\langle \pm I_2 \rangle$, and the induced action of $\Gamma(2)/\langle \pm I_2 \rangle$ is free. The quotient $X'(2) = \mathbb{H}/\Gamma(2)$ can be compactified to the modular curve by adding three cusps. The modular curve $X(2) \cong \text{Proj} \mathbb{C}[\lambda_0, \lambda_1]$ is known as the $\lambda$-line, which parameterizes the family
\[(4.3) \quad E_\lambda = \{[X : Y : Z] \in \mathbb{P}(1, 1, 2) \mid Z^2 = XY (X - Y)(\lambda_1 X - \lambda_0 Y)\}\]
of elliptic curves equipped with level-2 structures.

Consider the action of the group $\Gamma(2) \ltimes \mathbb{Z}^2$ on $\mathbb{H} \times \mathbb{C}$ defined by
\[(4.4) \quad (\gamma, m, n) : (\tau, z) \mapsto \left(\frac{a\tau + b}{c\tau + d}, \frac{z + m\tau + n}{c\tau + d}\right).\]

The action of the subgroup $\mathbb{Z}^2$ is free, and the action of the quotient group $\Gamma(2)$ on $\mathbb{H} \times \mathbb{C}/\mathbb{Z}^2$ is free outside of the four sections corresponding to the four 2-division points. Let $S'(2)$ be the
branched double cover of the quotient $\mathbb{H} \times \mathbb{C}/\Gamma(2) \times \mathbb{Z}^2$ along the images of those four sections. The natural projection

\begin{equation}
(4.5) \quad S'(2) \to X'(2), \quad (\tau, z) \mapsto \tau
\end{equation}

is an elliptic fibration, which can be identified with the family

\begin{equation}
(4.6) \quad V(Z^2 - XY(X - Y)(\lambda_1 X - \lambda_0 Y)) \subset \mathbb{P}(1, 1, 2)_{X:Y:Z} \times A^1_{\lambda} \to A^1_{\lambda}.
\end{equation}

The origin of the elliptic curve is given by $[1 : 0 : 0]$, and other 2-torsion points are given by $[1 : 1 : 0]$, $[\lambda_0 : \lambda_1 : 0]$, and $[0 : 1 : 0]$.

Let $\overline{S}(2)$ be the natural compactification

\begin{equation}
(4.7) \quad V(Z^2 - XY(X - Y)(\lambda_1 X - \lambda_0 Y)) \subset \mathbb{P}(1, 1, 2)_{X:Y:Z} \times \mathbb{P}^1
\end{equation}

of $S'(2)$. The natural morphism to $\mathbb{P}^1 \cong X(2)$ has three singular fibers of type $I_1$ at the cusps $\lambda = 0, 1, \infty$. The surface $\overline{S}(2)$ itself has three $A_1$-singularities at the singular points of the singular fibers, and we write its minimal resolution as $S(2)$.

**Proposition 4.1.** The elliptic fibration $S(2) \to X(2)$ has three singular fibers of type $I_2$ at $\lambda = 0, 1, \infty$, and the natural action of $SL(2, \mathbb{F}_2) \ltimes (\mathbb{Z}/2\mathbb{Z})^2$ on $S'(2)$ extends to $S(2)$.

**Proof.** In the coordinates of $\overline{S}(2)$, the three translations by the points $(1 : 1 : 0), (\lambda_0 : \lambda_1 : 0), (0 : 1 : 0)$ of order two can be written respectively as follows:

\begin{align}
(4.8) & \quad (X : Y : Z) \mapsto (\lambda(X - Y) : X - \lambda Y : \lambda(\lambda - 1)Z) \\
(4.9) & \quad (X : Y : Z) \mapsto (-X + \lambda Y : Y - X : (\lambda - 1)Z) \\
(4.10) & \quad (X : Y : Z) \mapsto (\lambda Y : X : \lambda Z)
\end{align}

By direct calculations, we can check that these are merely birational maps on $\overline{S}(2)$ but are genuine automorphisms on $S(2)$.

Consider the three-fold $S(2) \times X(2) S(2)$, which is a compactification of the $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$-covering of the quotient $\mathbb{H} \times \mathbb{C} \times \mathbb{C}/\Gamma(2) \times \mathbb{Z}^4$ by the action

\begin{equation}
(4.11) \quad (\gamma, m_1, n_1, m_2, n_2) : (\tau, z_1, z_2) \mapsto \left(\gamma(\tau), \frac{z_1 + m_1 \tau + n_1}{\epsilon \tau + d}, \frac{z_2 + m_2 \tau + n_2}{\epsilon \tau + d}\right).
\end{equation}

To a point $p = (\tau, z_1, z_2) \in S'(2) \times X'(2) S'(2)$, one can associate the quadruple

\begin{equation}
(4.12) \quad (E_\tau, \mathcal{O}(2o), \mathcal{O}(2z_1), \mathcal{O}(2z_2)),
\end{equation}

where $o = [0] \in E_\tau = \mathbb{C}/\mathbb{Z} \oplus \mathbb{Z}\tau$ is the origin. The quadruple $(4.12)$ is admissible if $2z_2 \not\sim 2o$. Two elliptic quadruples $(E_\tau, \mathcal{O}(2o), \mathcal{O}(2z_1), \mathcal{O}(2z_2))$ and $(E_\tau', \mathcal{O}(2o), \mathcal{O}(2z'_1), \mathcal{O}(2z'_2))$ are isomorphic if

1. the elliptic curves $E_\tau$ and $E_\tau'$ are isomorphic, i.e., $\tau' = \gamma(\tau)$ for some $\gamma \in SL_2(\mathbb{Z})$, and
2. $2z_i \sim 2z_i'$ for $i = 1, 2$, i.e., $z_i$ and $z_i'$ are related by 2-torsion translation.

Together, they form the group

\begin{equation}
(4.13) \quad G = SL_2(\mathbb{F}_2) \ltimes (\mathbb{Z}/2\mathbb{Z})^4
\end{equation}

acting on $S'(2) \times X'(2) S'(2)$, and one obtains the following:

**Proposition 4.2.** Two points $p, q \in S'(2) \times X'(2) S'(2)$ belong to the same orbit of the action of $G$ if and only if the associated quadruples are isomorphic.

Theorem 1.1 (2) follows from Proposition 4.2 and the equivalence between (2.27) and (2.28).
5. Potentials

One can use the homomorphism (3.6) to identify the two rings \( \mathbb{C} \left[ \text{Sym}^2(V_0 \otimes V_1) \right] \) and \( \mathbb{C} \left[ \text{Sym}^2(U) \right] \) in such a way that the invariant subrings are isomorphic;

\[
\mathbb{C} \left[ \text{Sym}^2(V_0 \otimes V_1) \right]_{\text{SL}(V_0) \times \text{SL}(V_1)} \cong \mathbb{C} \left[ \text{Sym}^2(U) \right]_{\text{SO}(U)}.
\]

Any symmetric matrix \( X \in \text{Sym}^2(U) \) can be diagonalized by the conjugate action

\[
g \cdot X = gXg^T
\]
of \( \text{SO}(U) \). The entries \( x_1, \ldots, x_4 \) of the resulting diagonal matrix is unique up to permutations. As a consequence, one has an isomorphism

\[
\mathbb{C} \left[ \text{Sym}^2(U) \right]_{\text{SO}(U)} \cong \mathbb{C}[x_1, x_3, x_4]_{\mathfrak{s}^4} = \mathbb{C}[f_1, f_2, f_3, f_4],
\]

where

\[
f_d = \sum_{i=1}^{4} x_i^d.
\]

The corresponding elements of \( \mathbb{C} \left[ \text{End} U \right]_{\text{SO}(U)} \) are

\[
f_d(X) = \text{tr} \left( X^d \right).
\]

It follows that

\[
\text{an element } X \in \text{Sym}^2(U) \text{ is unstable if and only if } X \text{ is nilpotent, and}
\]

\[
\text{the GIT quotient is given by } \text{Proj} \mathbb{C}[f_1, f_2, f_3, f_4] = \mathbb{P}(1, 2, 3, 4).
\]

With a potential \( \Phi \in \text{Sym}^2(V_0 \otimes V_1) \subset (V_0 \otimes V_1) \otimes (V_0 \otimes V_1) \), one can associate the quintuple \( (V_0, V_1, \Phi) \). This gives a morphism

\[
F: \mathcal{M}_{\text{pot}} \to \mathcal{M}_{\text{qui}}
\]
of stacks, which induces a rational map of the corresponding GIT quotients. This rational map can be identified with the natural projection from \( \overline{\mathcal{M}}_{\text{pot}} \cong \mathbb{P}^3/\mathfrak{S}_3 \) to \( \overline{\mathcal{M}}_{\text{pot}} \cong \mathbb{P}^3/(\mathfrak{S}_3 \ltimes (\mathbb{Z}/2\mathbb{Z})^3) \), and hence a posteriori is a morphism. Since the action \([x_1 : x_2 : x_3 : x_4] \mapsto [-x_1 : -x_2 : -x_3 : -x_4] \) is trivial on \( \mathbb{P}^3 \), the degree of this morphism coincides with the cardinality of the group \((\mathbb{Z}/2\mathbb{Z})^3/(\mathbb{Z}/2\mathbb{Z}) \cong (\mathbb{Z}/2\mathbb{Z})^2 \), which is four. The invariants \( g_4 \) and \( f_6 \) can be described in \( \mathbb{C}[f_1, f_2, f_3, f_4] \) as

\[
g_4 = \frac{f_1^4}{24} - \frac{f_1^2 f_2}{4} + \frac{f_1 f_3}{3} + \frac{f_2^2}{8} - \frac{f_4}{4},
\]

\[
f_6 = -\frac{f_1^6}{24} + \frac{3 f_1^4 f_2}{8} - \frac{2 f_1^2 f_3}{3} - \frac{3 f_2^2 f_3}{8} + \frac{3 f_2^4}{4} - \frac{f_3^2}{8} + \frac{3 f_2 f_4}{4} + \frac{f_4^2}{3}.
\]

6. Noncommutative conifolds

A quiver \((Q_0, Q_1, s, t)\) consists of a set \(Q_0\) of vertices, a set \(Q_1\) of arrows, and two maps \(s, t: Q_1 \to Q_0\) from \(Q_1\) to \(Q_0\). The vertices \(s(a)\) and \(t(a)\) are called the source and the target of the arrow \(a\). A path on a quiver is an ordered set of arrows \((a_n, a_{n-1}, \ldots, a_1)\) such that \(s(a_{k+1}) = t(a_k)\) for \(k = 1, \ldots, n - 1\). We also allow for a path \(e_i\) of length zero, starting and ending at the same
vertex \(i \in Q_0\). The path algebra \(\mathbb{C}Q\) of a quiver \(Q\) is the algebra spanned by the set of paths as a vector space, and the multiplication is defined by the concatenation of paths;

\[
(b_n, \ldots, b_1) \cdot (a_n, \ldots, a_1) = \begin{cases} 
(b_n, \ldots, b_1, a_n, \ldots, a_1) & s(b_1) = t(a_n), \\
0 & \text{otherwise}.
\end{cases}
\]

A cyclic path is a path \((a_n, \ldots, a_1)\) such that \(s(a_1) = t(a_n)\). There is a cyclic group action \((a_n, \ldots, a_1) \mapsto (a_{n-1}, \ldots, a_1, a_n)\) on the set of cyclic paths. A potential is an element \(\Phi\) of the invariant subspace \((\mathbb{C}Q)^{\text{cyclic}}\) of the subspace of \(\mathbb{C}Q\) spanned by cyclic paths. The partial derivative of a path by an arrow \(a\) is defined by

\[
\frac{\partial (a_n, \ldots, a_1)}{\partial b} = \begin{cases} 
(a_{n-1}, \ldots, a_1) & a_n = b, \\
0 & \text{otherwise}.
\end{cases}
\]

The Jacobi algebra of a quiver \((Q, \Phi)\) with potential is the quotient \(\mathbb{C}Q/(\partial \Phi)\) of the path algebra \(\mathbb{C}Q\) by the two-sided ideal generated by the partial derivatives. The path algebra of a quiver has a natural grading coming from the length of paths. The Jacobi algebra of a quiver has a natural grading coming from the length of paths. The Jacobi algebra \(\mathbb{C}Q/(\partial \Phi)\) inherits this grading if the potential \(\Phi\) is homogeneous.

An algebra \(A\) is homologically smooth if \(A\) has finite projective dimension as an \(A\)-bimodule (i.e. as a module over \(A^e = A \otimes_{\mathbb{C}} A^{\text{op}}\)). A homologically smooth algebra is a Calabi-Yau algebra of dimension 3 if there is an isomorphism \(f: A \xrightarrow{\sim} A^{[3]}\) such that \(f = f^!\) where \(A^{[3]} = \mathbb{R}\text{Hom}_{\mathbb{A}^e}(A, A^e)\) is the inverse of the rigid dualizing complex \([Gin06, \text{Definition 3.2.3}]\).

Let \(\mathcal{A}\) be a flat deformation of the noncommutative crepant resolution \(A_0 = \mathbb{C}Q/(\partial \Phi_0)\) of the conifold, where \(Q\) is the quiver in Figure 1.1 and \(\Phi_0\) is the potential in (1.2). We assume that \(A\) is a graded Calabi-Yau algebra of dimension 3, so that it can be described as the Jacobi algebra \(\mathbb{C}Q/(\partial \Phi)\) of a quiver \((Q, \Phi)\) with potential by \([Boc08, \text{Theorem 3.1}]\). The flatness of the deformation implies the invariance of the Hilbert series of the graded ring. It follows that the degree of the potential \(\Phi\) must be preserved under deformation.

Let \(\tilde{Q}\) be the quiver in Figure 1.4 obtained as the the double cover of the quiver \(Q\). The pullback of the potential \(\Phi\) by the natural homomorphism \(\mathbb{C}\tilde{Q} \to \mathbb{C}Q\) gives a potential \(\tilde{\Phi}\) of the quiver \(\tilde{Q}\). The quotient of the Jacobi algebra \(\mathbb{C}Q/(\partial \tilde{\Phi})\) by the two-sided ideal generated by \(b'_1\) and \(b'_2\) gives the path algebra of the quiver in Figure 1.3 with two relations among eight paths from \(v_{0,0}\) to \(v_{1,1}\). These two relations can be regarded either as a two-dimensional subspace of \(V_0 \otimes V_1 \otimes V_0\) or a one-dimensional subspace of \(V_0 \otimes V_1 \otimes V_1 \otimes V_1\). The latter coincides with the \(V_0 \otimes V_1 \otimes V_0 \otimes V_1\) component of the potential \(\tilde{\Phi}\), which we write as \(\Phi\) by abuse of notation. In this way, one obtains a quintuple \((V_0, V_1, V_0, V_1, \mathbb{C}Q)\) from a potential \(\Phi\). The potential \(\Phi\) is said to be geometric if the associated quintuple is geometric.

It follows from the construction of the \(\mathbb{Z}\)-algebra \(A = \bigoplus_{i,j \in \mathbb{Z}} A_{ij}\) from a quintuple that the Jacobi algebra \(\mathbb{C}Q/(\partial \Phi)\) is related to the \(\mathbb{Z}\)-algebra by

\[
e_i \mathbb{C}Q/(\partial \Phi) e_j = \begin{cases} 
\bigoplus_{n=0}^{\infty} A_{0,2n} & i = j, \\
\bigoplus_{n=0}^{\infty} A_{0,2n+1} & i \neq j.
\end{cases}
\]

The flatness of the deformation is equivalent to the geometricity of the potential \([VdB11, \text{Lemma 4.9}]\). Geometricity of \(\Phi\) implies that the associated \(\mathbb{Z}\)-algebra \(A\) is AS-regular of dimension 3 \([VdB11, \text{Theorem 4.31}]\), which in turn implies that \(\mathbb{C}Q/(\partial \Phi)\) is Calabi-Yau of dimension 3. The
subring $R = e_0\mathbb{C}Q/(\partial \Phi)e_0$ of the Jacobi algebra of a geometric potential will be called a noncommutative conifold.

A categorical resolution \cite{KL} Definition 1.3 (cf. also \cite{Kuz08, Lun10}) of a ring $R$ is a smooth cocomplete compactly generated triangulated category $\mathcal{F}$ and an adjoint pair $\pi^*: D(R) \rightleftarrows \mathcal{F} : \pi_*$ of functors such that

1. the natural morphism $\text{id}_{D(R)} \to \pi_*\pi^*$ of functors is an isomorphism,
2. both $\pi^*$ and $\pi_*$ commute with arbitrary direct sum, and
3. $\pi_*(\mathcal{F}^c) \subset D^b \text{mod}(R)$.

When $R$ is the subring $e_0\mathbb{C}Q/(\partial \Phi)e_0$ of the Jacobi algebra $\mathbb{C}Q/(\partial \Phi)$ of the conifold quiver with a geometric potential $\Phi$, the adjoint pair $\pi^* \vdash \pi_*$ of the functors

\begin{align*}
\pi_* : D(\mathbb{C}Q/(\partial \Phi)) &\to D(R), \quad M \mapsto M e_0 \\
\pi^* : D(R) &\to D(\mathbb{C}Q/(\partial \Phi)), \quad N \mapsto N \otimes_R e_0\mathbb{C}Q/(\partial \Phi)
\end{align*}

is a categorical resolution of the noncommutative conifold $R$.

### 7. Donaldson-Thomas invariants

Let $\tilde{Q}$ be the quiver in Figure 7.1 equipped with the potential $\tilde{\Phi}$ inherited from a potential $\Phi$ of the conifold quiver $Q$. A framed representation of the conifold quiver is a module over the Jacobi algebra $\mathbb{C}Q/(\partial \tilde{\Phi})$, i.e., a collection $M = ((V_0, V_1, V_\infty), (A_1, A_2, B_1, B_2, I))$ of vector spaces $(V_0, V_1, V_\infty)$ and maps

\begin{align*}
A_i : V_0 &\to V_1, \quad i = 1, 2, \\
B_i : V_1 &\to V_0, \quad i = 1, 2, \\
I : V_\infty &\to V_0
\end{align*}

satisfying the relation $(\partial \tilde{\Phi})$. The dimension vector of $M$ is given by

\begin{equation}
v = (v_0, v_1, v_\infty) = (\dim V_0, \dim V_1, \dim V_\infty).
\end{equation}

A stability parameter is an element $\theta = (\theta_0, \theta_1, \theta_\infty) \in \mathbb{R}^3$. The slope of a representation $M = ((V_0, V_1, V_\infty), (A_1, A_2, B_1, B_2, I))$ with respect to the stability parameter $\theta$ is defined by

\begin{equation}
\theta(M) = \frac{\theta_0 \dim V_0 + \theta_1 \dim V_1 + \theta_\infty \dim V_\infty}{\dim V_0 + \dim V_1 + \dim V_\infty}.
\end{equation}

A representation $M$ is $\theta$-stable if one has

\begin{equation}
\theta(M') < \theta(M),
\end{equation}

Figure 7.1. The framed conifold quiver
for any non-zero proper submodule $M' \subset M$. The moduli space of framed $\theta$-stable representations wit dimension $v$ will be denoted by $\mathcal{M}_\theta(v)$. The numerical DT invariant is defined as the weighted Euler characteristic \(^{(1.3)}\) with respect to the Behrend function on $\mathcal{M}_\theta(v)$. We expect that the numerical DT invariant is independent of the potential $\Phi$.

The numerical DT invariant has a motivic refinement, which is defined in terms of virtual motives \(^{(BBS13)}\). When the potential is the one given in \(^{(1.2)}\), then $\mathcal{M}_\theta(v)$ for $v = (1, 1, 1)$ and $\theta = (-1, -1, 2)$ is the resolved conifold

\[(7.7) \quad Y = [(\mathbb{A}^4 \setminus \{(0, 0)\}) \times \mathbb{A}^2] / \mathbb{C}^\times \cong Spec_{\mathbb{P}^1} (Sym^* (\mathcal{O}_{\mathbb{P}^1}(1) \oplus \mathcal{O}_{\mathbb{P}^1}(1))) ,\]

and the virtual motive is given by

\[(7.8) \quad [Y]_{vir} = L^{-3/2}[Y],\]

where $L$ is the Lefschetz motive. When the potential is given by

\begin{align*}
\Phi &= \alpha a_1 b_1 a_1 b_1 + \beta a_1 b_2 a_1 b_2 + \gamma a_2 b_1 a_2 b_1 + \delta a_2 b_2 a_2 b_2, \\
(7.10) &\quad a_1 (\alpha b_1^2 + \beta b_2^2) = 0, \\
(7.11) &\quad a_2 (\gamma b_1^2 + \delta b_2^2) = 0, \\
(7.12) &\quad b_1 (\alpha a_1^2 + \beta a_2^2) = 0, \\
(7.13) &\quad b_2 (\gamma a_1^2 + \delta a_2^2) = 0.
\end{align*}

The motivic DT invariant in this case is given by

\[(7.14) -\frac{L^{-3/2}}{\Phi^{-1}(1)} - [\Phi^{-1}(0)]\]

by \(^{(BBS13) \text{Theorem B.1}}\), where $\Phi$ is considered as a map from $Y$ to $\mathbb{A}^1$. Being the difference of two subschemes, this motive is clearly distinct from \(^{(7.8)}\).
