Intern, College of Medicine, Taibah University, Medina, Saudi Arabia

Abstract

Background: Breast cancer is the most common malignancy among women in Saudi Arabia. Despite the availability of early detection methods to diagnose breast cancer, a huge number of women are still unaware about these methods. This study was conducted to identify the attitude of women in Medina toward breast cancer screening methods, including breast self-examination (BSE), clinical breast examination (CBE) and mammography.

Materials and methods: A cross sectional survey has been conducted on 124 women aged from 39 and older, who attended Taibah Medical Center for cancer screening either by doctor’s recommendation, family or friends advice, or by herself. Face to face questionnaire was used to collect data. All data were analyzed by statistical analysis system software.

Results: The results showed only 35.5%, 27.4% and 37.8% of participants reported that they practiced BSE, CBE and annual mammography, respectively. Only 27.3% of women practiced BSE once per month, and 8.8% visited doctor annually for CBE. Both educational level and family history were significantly related to BSE. 57.7% of the participants who had positive family history practiced BSE, and 56.0% of the participants who practiced BSE were highly educated. Lacking awareness about BSE is the most important barrier in not practicing BSE, while not having a breast lump was the reason for not undergoing either clinical breast examination (38.7%) or periodic mammography (54.9%).

Conclusion: This study emphasized the need for massive health education program to increase awareness, and improve the attitude of women toward breast cancer screening methods.

Keywords: Breast cancer; Screening; Self-examination; Mammography

Introduction

Breast cancer is the most frequent malignancy among Saudi women and the ninth leading cause of death in Saudi Arabia in 2010 [1,2]. Breast cancer incidents have been escalating faster in the Kingdom and is currently ranked number one among cancerous diseases in women in the country of Saudi Arabia [3,4]. Breast cancer is the second leading cause of mortality and morbidity in women of western countries [5].

Breast cancer is preventable through early detection and healthy lifestyles that improve women’s health and decrease the costs relating to cancer death [6]. Therefore, effective screening programs are the best way to detect cancer before experiencing any symptoms [7]. Breast cancer screening methods include breast self-examination (BSE), clinical breast examination (CBE) and mammograms [8]. These effective ways of screening are consistent with and show that there is relatively little current emphasize on the first published results of the New York randomized control trial in 1997 [9].

Ravichandran et al. conducted a study in the Riyadh region that revealed only 23.1% of studied subjects practiced BSE [10]. Hussein et al. carried out a study on 1000 participants in Hail city and its rural neighborhoods, and found that 50% of all female participants >16 years old did not practice BSE [11]. Some studies were based on selected groups, like students, and findings revealed an imbalance between the knowledge and practice of BSE, CBE and mammogram [12]. However, in the Gulf region, specifically in Saudi Arabia several previous studies conducted in different regions that assessed the awareness, knowledge, and attitude towards breast cancer among female Saudi teachers, female university students, and women respectively, indicated that many women are still lacking information about breast cancer screening [13,14].

Objective

To identify the prevalence and effectiveness in breast cancer screening methods among women.

Subjects and Methods

This study carried out to investigate the attitude of women about breast cancer screening by using a cross-sectional survey of women aged from 39 years and older who were attending Taibah Medical Center for breast cancer screening for a period of four months (2015-2016). The sample comprised 124 Saudi and non-Saudi females who visited the center for a mammogram. A face-to-face survey (10 minutes per each subject) was used to collect the data after obtaining written consent from each participant.

The study employed a pre-designed structured, reliable and validated questionnaire to collect the data. Those who refused to participate or gave incomplete information were excluded from the study. Study approval was obtained from the Ethics Committee of Taibah College of Medicine, Medina, Saudi Arabia (TUCD-REC). A consent form was given at the beginning of the questionnaire explaining the purpose of the study, and requested their voluntary participation. The women’s privacy and confidentiality were assured. The questionnaire was constructed based on the objective of the study, including questions on socio-demographic data (such as: age, marital status, nationality, education level, work status and income), a commitment to do a breast checkup including breast self-examination, breast clinical examination and mammography as well as their reasons for not doing them.

All data was analyzed using the statistical analysis system (SAS) software package [18]. Data was presented using frequencies. The women’s practice of breast cancer screening (breast self-examination, clinical breast examination and mammography) was assessed and compared by women’s characteristics using appropriate statistical tests (Chi square and Fischer exact test). The criteria of significance were considered at a P-value of ≤ 0.05. Furthermore, the barrier items preventing women from the practice of the studied breast cancer screening methods were assessed by the frequency number and percent of each studied barrier item for each studied breast cancer screening.

Results

During the study period, 124 women were interviewed at Medina cancer screening center at Medina city, Saudi Arabia. Fifty women (40.3%) visited the center according to doctors’ recommendation, 27 women according to their family and friends talks and 47 (38%) by women herself. Of the studied 124 women, there were 71 women (57.3%) reported that they practiced mammography for the first time during their life and the remaining 53 (42.7%) women had reported to practice mammography regularly. Of those 53 women, 20 (37.8%) had practiced mammography once every year, 7 (13.2%) every two years, 26 (49%) every three years. Of all the women studied, 63 women reported that they have been referred by doctors to do the mammography. Of the studied 124 women, there were 44 (35.5%) reported that they practice BSE and 34 (27.4%) reported that they practice clinical examination.

Among the studied women reporting breast self-examination (44 out of 124), there have been 13 women (27.3%) practicing BSE once monthly, only 5 women (11.3%) do it 2-3 days after their period ends, 26 women (59%) examine the breast while lying down, 34 (77.3%) raise their arms up and look for changes, 23 (52.3%) examine and press their nipples for any type of discharge, and 32 (73%) examine lymph nodes in their armpit. Of the studied women practicing clinical breast examination (34 out of 124), 3 women (8.8%) reported that they visited a doctor to examine their breasts every 2 months, 13 (38.3%) every 6 months, 3 (8.8%) every year and 15 (44.1%) every three years.

Half of the studied women were aged ≥ 50 years, and 76.6% of the studied women were Saudis. About three-fourth of the studied women were married (72.6%), and didn’t work (house wife) (76.6%), and less than university educated (79.8%). The majority of the studied women (96.8%) reported less than 20,000 SR as family’s monthly income. The studied women reported that they have had a positive family history regarding breast cancer and having breast problems were 21.0% and 34.7%, respectively. The contraceptive pill use was 2.4% among all studied women while the ex-users were 56.7%.

In Table 2 showed the distribution of breast self-examination among the studied women by their characteristics. The higher significant proportion of women who practice breast self-examination are young women less than 40 years (100%) and those from 40 to less than 50 years (38.9%), highly educated women (56%), high monthly income women (75%) and those reported positive family history for breast cancer (57.7%). Although not significant, the proportion of breast self-examination was higher among non-Saudis, married and divorced, employed and retired, women having breast problems, and contraceptive pill users and ex-users.

In Table 3 presented practice of clinical breast examination among the studied women by their characteristics. Significant high proportions of women were found to do clinical breast examination among employed (41.1%), retired women (57.0%) and those with a monthly family income from 5000-20000 SR (38.5%) and those with monthly

*Significant

In terms of barrier for BSE, lacking awareness of this method (41.0%) was the most important factor in not practicing BSE among the participants in this study. This proportion is much lesser than a study in Jeddah reported that 47.5% of females participants knew how to perform BSE [4]. As well, based on the study conducted in King Abdulaziz Medical City, Riyadh, Saudi Arabia, had shown that

Discussion

Globally, breast cancer is the second leading cause of death in women and ranked number one among cancerous diseases in women who live in Saudi Arabia [3-5]. The aim of this study was to investigate the attitude of women toward breast cancer screening. In the present study, breast self-examination, clinical breast examination and periodic mammography screenings were reported by 35.5%, 27.4%, 37.8% of women who participated in the study, respectively. The reported results of practicing breast cancer screening from other studies conducted in neighboring countries (Qatar and Jordan) showed BSE, CBE and periodic mammography screening were 13.9%, 31.3% and 26.9%, respectively in Qatar, [19] while 34.9%, 16.8% and 8.6%, respectively in Jordan [20]. Similarly, on regular performance of BSE, our data found 27.3% of participants have performed BSE once per month. However, previous study was conducted among Iranian women showed the regular performance of BSE was 10.1% [21]. Theses reported results reflect the differences of attitude toward BCS among different societies.

Regarding the performance of BSE, our findings in the present study emphasized the importance of social campaigns and mass media in teaching women the correct performance of practicing BSE. The data showed that the performance level of practicing BSE among the participants according to baseline technique of BSE was lacking, only 59% of participants examine breast in lying down position, 77.3% raise their arm up and look for changes, 52.3% examine and press their nipple for any type of discharge and 73% examine lymph nodes in their armpit. Our data indicated that young women (less than 40) have 100% practicing BSE while 38.9% and 29.3% among 40 to less 50 year old and more than 50 year old women, respectively. These reported results were not in line with Ravichandran et al. study, where he found that there is no significant association between the different age groups and practicing BSE [10].

In our study, positive family history was remarkable and a promoting factor to keep practicing BSE among the participants. More than half (57.7%) of positive family history participants practiced BSE while only 29.6% of negative family history participants practiced BSE. As stated in study was conducted on 374 women in Riyadh, those women who perceives family history as a risk factor that increases her susceptibility of having breast cancer would be more likely to be committed to do breast examinations in regular manner [22]. These findings reflect a positive attitude among women who have family history of breast cancer.

According to the present study more than half (56.0%) of educated women (university and higher education) have a positive attitude about BSE. The data in this study showed practicing BSE were 30.5%, 50.0% and 57.1% for housewife, employed participants and retired respectively, this result was not in line with previous study that showed employment was the only significant socio-demographic predictor of BSE practice [22].

In the present study more than half (56.0%) of educated women (university and higher education) have a positive attitude about BSE. The data in this study showed practicing BSE were 30.5%, 50.0% and 57.1% for housewife, employed participants and retired respectively, this result was not in line with previous study that showed employment was the only significant socio-demographic predictor of BSE practice [22].

Table 4: Frequency distribution of mammography among the studied women by their characteristics.

| Barrier items | n (%) |
|---------------|-------|
| Breast self examination (n=124) |       |
| 1. Lacking of awareness          | 51 (41.0) |
| 2. Not having breast problem     | 27 (21.8) |
| 3. Forgetting to do it           | 9 (7.3)   |
| 4. Important test                | 4 (3.2)   |
| 5. Fearing of finding lump       | 2 (1.6)   |
| Clinical breast examination (n=124) |       |
| 1. Not having breast problem     | 48 (38.7) |
| 2. Lacking of awareness          | 36 (29.0) |
| 3. Embarrassment                 | 8 (6.4)   |
| 4. Fearing of finding lump       | 2 (1.6)   |
| Mammography (n=71)*              |       |
| 1. Not having breast problem     | 39 (54.9) |
| 2. Lacking of awareness          | 29 (40.9) |
| 3. Not requested by doctor       | 12 (16.9) |
| 4. Fearing of results            | 2 (2.8)   |
| 5. Fearing of pain               | 1 (1.4)   |

*Significant

Table 5: Reasons of not performing breast cancer screening among the studied women.

the reasons for not doing BSE as reported by 235 women were: not knowing how to examine their breast [22].

Despite breast cancer screening is being offered for free in our city, the study revealed that only 12% of the families with low monthly income (<5000 SR) came for CBE and 30.0% of them came to do frequent mammography screening in comparable with 25% of high monthly income (>20,000 SR) came for CBE and 66% of them came to do frequent mammography screening. While in another study, found that the cost of screening had a crucial effect on women not seeking breast cancer screening [23].

Barriers preventing women from seeking clinical breast examination were: not having breast lumps (38.7%) and lacking awareness (29.0%). Similarly, a recent study reported that not having symptoms (92%) and not knowing that screening was needed (40%) were the main reasons for not undergoing either clinical breast examination or mammography [24].

In reference to another study, Women were not obtaining access to the screening program due to several factors, and most importantly, lack of education and awareness [15]. Data in this study were in concordance with the previous study which indicated that education level has a strong impact on women performance toward breast cancer screening. Out of 124 studied women, 56% of highly educated females level has a strong impact on women performance toward breast cancer screening. Out of 124 studied women, 56% of highly educated females performed breast self-examination or mammography [24].

The strengths of this study include that the study questionnaire was comprehensive and addressed almost all items as well as wide range of personal and belief barrier factors discussed in previously published Saudi and non-Saudi studies. The study questionnaire has also been validated by specialist in this filed; including radiologist, oncologist and an epidemiologist. To the best of our knowledge, this study is the first to study practice and barriers of different breast cancer screening methods in Medina region in Saudi Arabia. Dissemination of these
findings to Medina Cancer Breast Screening Center (MCBSC) will help to know the current situation and to plan different breast awareness and health education programs to correct some incorrect beliefs preventing women in Medina and to encourage them attending the center.

The limitations of this study should not be overlooked. Self-selection bias may have been a limitation factor in this study because all women were selected from single center, which should not attract women from different educational and family income sectors to attend. However, because of socio-demographic distributions observed in this study, the sample appeared representative and this factor appeared to have no role in the study findings.

Conclusions

Our results support the need for new emphasis in health educational program throughout promotion campaigns, mass media or even encouragement by health professionals. Moreover, increase the nationwide breast cancer screening awareness to engage them in breast cancer preventive practice. Further research is needed to shed more light on this occurrence, particularly on Medina’s population, and suggests future barriers and solution direction.

Acknowledgements

We are grateful to the healthcare providers at Taibah Breast Cancer Screening Center in Medina for their contributions in this study. The authors would like to thank all patients participated in this study.
