(Received 5 November 2020 and accepted in revised form 8 May 2022)

Abstract. For the family of double standard maps $f_{a,b} = 2x + a + (b/\pi) \sin 2\pi x \pmod{1}$ we investigate the structure of the space of parameters $a$ when $b = 1$ and when $b \in [0, 1)$. In the first case the maps have a critical point, but for a set of parameters $E_1$ of positive Lebesgue measure there is an invariant absolutely continuous measure for $f_{a,1}$. In the second case there is an open non-empty set $E_b$ of parameters for which the map $f_{a,b}$ is expanding. We show that as $b \nearrow 1$, the set $E_b$ accumulates on many points of $E_1$ in a regular way from the measure point of view.

Key words: double standards maps, absolutely continuous invariant measure, expansion

2020 Mathematics Subject Classification: 37E10 (Primary); 37C40 (Secondary)

1. Introduction

In one-dimensional dynamics, a lot is known about the families of smooth maps with a critical point, such as quadratic maps, and about the maps that have no critical points (local diffeomorphisms of the circle). Here we start to investigate what happens at the interface of those two cases.

Consider the family of double standard maps of the circle onto itself, given by

$$f_{a,b} = 2x + a + \frac{b}{\pi} \sin 2\pi x \pmod{1}, \quad (1.1)$$

where the parameters $a, b$ are real, $a \in [0, 1)$ and $b \in [0, 1]$. In fact, we consider $a$ from the circle $\mathbb{R}/\mathbb{Z}$, but since we are mostly working locally (and far from $a = 0$), considering $a$ real is simpler. This family of maps was introduced in [19].

For $b = 1$, maps of the family (1.1) have a unique cubic critical point (at $c = 1/2$) and negative Schwarzian derivative. Thus, they behave similarly to quadratic maps. In particular, there is a set of parameters $a$ for which there is an invariant probability measure,
unfortunately continuous with respect to the Lebesgue measure. For \( b < 1 \), there is no critical point, so the maps are local diffeomorphisms. Complexification of the maps, obtained by conjugacy via \( e^{2\pi i x} \), gives the family
\[
\gamma_{a,b}(z) = e^{2\pi i a} z^2 e^{b(z-1/z)}.
\]

Those maps are symmetric with respect to the unit circle, and factored by this symmetry, they have only one critical point and no asymptotic values in \( \mathbb{C} \setminus \{0\} \). Therefore a map \( f_{a,b} \) has at most one attracting or neutral periodic orbit (see [9, 10, 19]).

One can also look at the family of double standard maps as a hybrid between the family of standard maps, studied by Arnold (see [1]) and important in the creation of the Kolmogorov–Arnold–Moser theory, and expanding maps of the circle (see [23]). Of course instead of maps of degree 2 one can take maps of higher degrees and the results will be practically the same (but we would introduce one more parameter and lose the nice name of the family).

Some recent work has been done for classes of families that include double standard maps. Misiurewicz and Rodrigues studied them in [19, 20]. Benedicks and Rodrigues [4] investigated symbolic dynamics for this family. Universality for critical circle covers was studied by Levin and Świa̧tek [14]. Levin and van Strien [15] proved complex bounds, quasisymmetric rigidity and density of hyperbolicity for a class of real analytic maps which includes the double standard maps. Fagella and Garijo [10] studied a class of complex maps containing the maps \( g_{a,b} \). Dezotti [9] also considered maps \( g_{a,b} \) and, using complex methods, obtained important results on the real case.

As for the Arnold family, for the double standard family we call the sets for which there is an attracting periodic orbit of a given type (period plus combinatorics) tongues. Dezotti [9] proved that tongues are connected. The lowest tongue tip is at \( b = 1/2 \), for the period-1 tongue. If \( 0 < b < 1/2 \), the map \( f_{a,b} \) is expanding. At higher \( b \)-levels there may be finitely or infinitely many tongues (see [19]). In particular, at the critical level \( b = 1 \) all tongues are present, and it is easy to prove that they are dense at this level (see [15]). We show (in Theorem A) that at the lower levels \( f_{a,b} \) can have an attracting or neutral periodic orbit, and otherwise it is expanding. Moreover, the set of expanding maps is dense in the complement of the tongues.

For simplicity, we will be using the notation \( f_a \) for \( f_{a,1} \). A parameter \( a_0 \) will be called an MT parameter (for Misiurewicz–Thurston) if the trajectory of the critical point \( c = 1/2 \) is preperiodic (but not periodic).

In this case \( f_{a_0} \) has an absolutely continuous invariant measure [17], and it is also true that the critical value \( f_{a_0}(\frac{1}{2}) \) satisfies the Collet–Eckmann condition, that is, that there exist \( C_{CE} > 0 \) and \( \kappa_1 > 0 \) such that for \( a = a_0 \),
\[
(f_a^n)'(f_a(c)) \geq C_{CE} e^{\kappa_1 n} \quad \text{for all } n \geq 0,
\]
which implies the existence of an absolutely continuous invariant measure [22, 25].

Using the methods of [2] it is possible to prove the following proposition.

PROPOSITION 1.1. There is a set of positive Lebesgue measure \( \tilde{E}_1 \) so that for all \( a \in \tilde{E}_1 \) there is \( n_0(a) \) such that
\[
(f_a^n)'(f_a(c)) \geq e^{a^{2/3}} \quad \text{for all } n \geq n_0(a),
\]
Here $\frac{2}{3}$ can be replaced by any constant $\sigma < 1$.

A parameter exclusion requiring
\[
\text{dist}(f^j_a(c), c) \geq e^{-\sqrt{j}}, \quad j \geq 1,
\]
will be sufficient to prove (1.3) and then Jacobson’s theorem also follows.

Using the methods of Large deviations of [3] it is possible to prove the following result.

**Proposition 1.2.** There is a set of positive Lebesgue measure $E_1$ and some $\kappa > 0$ such that for all $a \in E_1$,
\[
(f^n_a)(f_a(c)) \geq Ce^{\kappa n} \quad \text{for all } n \geq 0.
\]  

For a similar result, see [24].

In the present paper we will consider the non-critical case $0 < b < 1$ and use more elementary methods based on [2], which give stretched exponential growth of the type
\[
(f_{a,b}^n)'(f_{a,b}(c)) \geq e^{n^{2/3}}, \quad n_0 \leq n \leq N(a,b),
\]
for all $a \in \tilde{E}_b$ for a set $\tilde{E}_b$, which is a finite union of intervals. To obtain this it is sufficient to carry out parameter exclusions of the type
\[
\text{dist}(f^j_{a,b}(c), c) \geq C_1e^{-\sqrt{j}}, \quad j \geq 1,
\]
and then prove exponential expansion in §8. The proof is discussed further at the end of this section.

We will outline the proof of Proposition 1.1 after the proof of Theorem A.

By the results of [5, 6], if $f_a(c)$ satisfies the Collet–Eckmann condition, then $f_a$ has an absolutely continuous invariant measure. This is the analogue of Jakobson’s theorem [11] in this case.

It is also possible to prove (1.2) for $a$ in a set $E_1$ of positive Lebesgue measure, but with the present setup this would require the method of large deviations of [3], and this is not required when $0 < b < 1$.

Let us introduce some notation. For a fixed $b$, let us denote the sets of those parameters $a$ for which $f_{a,b}$ has an attracting (respectively, neutral) orbit $T_b$ (respectively, $TN_b$). Moreover, let $E_b$ be the set of those parameters $a$ for which $f_{a,b}$ is expanding, that is, there exist $C > 0$ and $\kappa > 0$ such that
\[
(f_{a,b}^n)'(x) \geq Ce^{\kappa n} \quad \text{for all } n \geq 0, \text{ for all } x \in \mathbb{T}.
\]
By the result of Mañé [16], if $a$ does not belong to $T_b$ or $TN_b$, then it belongs to $E_b$. Observe that by the definition, a small perturbation of an expanding map is also expanding, so $E_b$ is open. In fact, the set $E = \{(a, b) : a \in E_b, 0 \leq b < 1\}$ is open in $[0, 1) \times [0, 1)$.

Note that our definition of $E_1$ or $\tilde{E}_1$ is quite different from the non-critical case, that is, the case of $E_b$ for $b < 1$. Nevertheless, there are some common features of the non-critical case, because if $f_{a,b}$ is expanding, then by the results of Krzyżewski and Szlenk [12], or by the Lasota–Yorke theorem [13], there exists an absolutely continuous invariant measure.

Extending the methods of the proof of (1.3), we prove the following theorem.
THEOREM A. Let $a_0$ be an MT parameter for the family $\{f_a\}$. Denote $\omega(\varepsilon) = (a_0 - \varepsilon, a_0 + \varepsilon)$. Then for some $\varepsilon_0 > 0$ there is a function $b_0 : (0, \varepsilon_0) \to (0, 1)$ such that

$$\lim_{\varepsilon \to 0} \inf_{\varepsilon < 0} \left\{ |E_b \cap \omega(\varepsilon)| : b \in (b_0(\varepsilon), 1] \right\} = 1.$$ 

Here $|A|$ denotes the Lebesgue measure of the set $A$.

This can be considered as the main result of the paper. It gives a quantitative relation between the behavior of the system for $b < 1$, where the maps are local diffeomorphisms, and for $b = 1$, the critical case.

Finally, we prove a topological result, using very different methods.

THEOREM B. For each $b < 1$, the set $E_b$ is dense in the complement of $T_b$. In particular, every interval of the parameters $a$ either is contained in a closure of one tongue or intersects $E_b$.

The above theorem in some sense complements Theorem A. Locally it says less about the set $E_b$, but it applies to all $b < 1$, not only to $b$ sufficiently close to 1 (moreover, this closeness in Theorem A depends on $a_0$).

This paper is organized as follows. In §2 we introduce notation and some definitions that we will use throughout the paper. In §3 we prove the transversality condition for maps of the family (1.1). In §4 we prove that we have exponential growth of the derivative for an orbit of a map $f_{a,b}$ that moves outside an open interval containing the critical point when $(a, b)$ is a small perturbation of an MT parameter $(a_0, 1)$. In §5 we describe the induction including its startup and prove that the conditions on the induction statement are satisfied for the first free return time. Furthermore, we define the bound period and prove some results concerning the derivative growth during the bound period. In §6 we prove the global distortion lemma and in §7 we start the proof of Theorem A. In §8 we finish this proof. Finally, in §9 we prove Theorem B.

Let us indicate what is technically new in this paper compared to previous work. The proof of Theorem A is based on techniques in [2, 3].

The main strategy of the proof of Theorem A is the inductive proof of

$$ (f_{a,b}^n)'(f_{a,b}(c)) \geq C_2 e^{n^{2/3}}, \quad (1.9) $$

up to a certain time $\hat{N}$.

The set $\tilde{E}_1$ in the critical case $b = 1$ is a Cantor set of positive measure represented as

$$ E_1 = \bigcap_{n=0}^{\infty} A_n, $$

where each $A_n$ is a disjoint union of intervals $\{I_n^j\}$. Here $A_{n+1} \subset A_n$ and the set $A_{n+1}$ are defined by removing subintervals of each $I_n^j$ according to two rules. First those subintervals that do not satisfy an approach rate condition (1.4) for the critical point (or inflexion point) $c = \frac{1}{2}$ are deleted. This replaces the basic assumption (BA) in [2, 3]. In the non-critical case $0 < b < 1$ this condition corresponds to (1.7).
The proof of Theorem A is different from that of Proposition 1.1 in the critical case due to the fact that the behavior at the inflexion point \( c = \frac{1}{2} \) is given by the Taylor series

\[
f_{a,b}(x) = a + (2 - 2b)\left(x - \frac{1}{2}\right) + \sum_{k=1}^{\infty} a_{2k+1}(x - \frac{1}{2})^{2k+1}
\]

\[
= a + (2 - 2b)\left(x - \frac{1}{2}\right) + g(x).
\]

Here \( g(x)/(x - \frac{1}{2})^3 \) is bounded above and below by strictly numerical positive constants, depending only on the MT map \( f_{a_0} \). Furthermore, \( g'(x)/(x - \frac{1}{2})^2 \) has similar bounds from above and below.

This means that when a point \( y = f^n_{a,b}(x) \) is close to \( c = \frac{1}{2} \), the derivative \( f'_{a,b}(y) \) will be dominated either by \( 2 - 2b \) or by the quadratic term \( g'(y) \) and these two cases will be treated differently.

The induction in the non-critical case \( b < 1 \) can actually be terminated at the time \( \hat{N} \) defined by the condition that the constant term in the derivative \( 2 - 2b \) can be of size comparable to \( g'(x) \), which is quadratic, that is,

\[
2 - 2b \sim (e^{-\sqrt{N}})^2,
\]

where \( \sim \) means that the two sides are comparable within fixed constants, which depend only on \( f_{a_0} \). Defining \( \hat{N} \) this way, we can stop the induction at time \( \hat{N} \) and the remaining set \( E_b = \bigcap_{n=0}^{\hat{N}} A_n(b) \) is a finite union of intervals.

Another new aspect of the present paper is that for \( b < 1 \) the condition of Collet–Eckmann type (again with \( c = \frac{1}{2} \))

\[
(f^n_{a,b})'(f_{a,b}(c)) \geq Ce^{kn} \quad \text{for all } n \geq 0,
\]

is no longer sufficient for the existence of absolutely continuous invariant measures for \( f_{a,b} \). There is, however, another argument given in §8 which uses (1.11) together with bound period estimates (see §4) which prove uniform hyperbolicity (1.8). As general references for the theory of one-dimensional maps we mention [7, 8, 18, 21].

2. Notation

Throughout this paper, \( C \) is a general numeric constant. For a set \( A \subset \mathbb{R} \) we will denote by \( |A| \) its Lebesgue measure.

Consider the family of double standard maps given by (1.1) with \( b = 1 \). Throughout this paper we write \( f_a(x) = f_{a,1}(x) \) and denote by \( \xi_j(a) \) the orbit of the critical point:

\[
\xi_j(a) = f_a^j(c).
\]

For a general \( b \leq 1 \), we also use the notation \( \xi_j(a,b) = f^j_{a,b}(c) \). It is clear that when \( b < 1 \), the point \( c = \frac{1}{2} \) is an inflexion point. Sometimes we also use the notation \( f(x,a,b) \) for \( f_{a,b}(x) \) and \( f(x,a) \) for \( f_a(x) \).

By \( \partial_a f^j_{a,b}(x) \) we denote the partial derivative of \( f^j_{a,b}(x) \) with respect to \( a \) and by \( \partial_a f^j_a(x) \) the partial derivative of \( f^j_a(x) \) with respect to \( a \).
Definition 2.1. A parameter \( a = a_0 \) will be called an MT parameter (for Misiurewicz-Thurston), if there exist an integer \( m \) and a period length \( \ell \) such that \( \xi_m(a_0) \) is a periodic point of \( f_{a_0} \) of period \( \ell \) and the multiplier \( \Lambda := (f_{a_0}^\ell)'(\xi_m(a_0)) \) is greater than 1.

As in [2, 3], we define a partition \( Q = \{I_{r,l}\} \) of the return interval \( I^* = (c - \delta, c + \delta) \), where \( \delta = e^{-r_\delta} \). We first divide \( I^* \),

\[
I^* = \bigcup_{r = r_\delta}^{\infty} I_r \cup \bigcup_{r = r_\delta}^{\infty} I_{-r},
\]

where \( I_r \) is the interval \((c + e^{-r-1}, c + e^{-r})\) for \( r_\delta \leq r < \infty \), and \( I_{-r} \) is the interval \((c - e^{-r}, c - e^{-r-1})\).

We then subdivide \( I_r \) into \( r^2 \) intervals of equal length with disjoint interiors as follows:

\[
I_r = \bigcup_{\ell = 0}^{r^2 - 1} I_{r,\ell}.
\]

For convenience we also use the convention that \( I_{r,2} = I_{-1,0}, r > 0 \), and the analogous convention for \( r < 0 \).

Note that we have \(|I_{r,l}| = e^{-r}/r^2(1 - e^{-1})\) and \(|I_r| = e^{-r}(1 - e^{-1})\). We will also need the extended interval

\[
I_{r,\ell}^+ = I_{r,\ell - 1} \cup I_{r,\ell} \cup I_{r,\ell + 1}.
\]

For technical reasons we will also need a partition \( Q' = \{I_{r,l}\} \), \(|r| \geq r_1^1\), of an interval \( I^{**} = (c - \delta_1, c + \delta_1) \), where \(|r| \geq r_0^1\), for some \( r_0^1 < r_\delta \), that is, \( \delta_1 = e^{-r_0^1} > \delta \).

An important tool in this paper is a sequence of partitions \( \mathcal{P}_n, n = 0, 1, 2, \ldots \), of the parameter space which is induced by the phase space partition. We define

\[
\mathcal{E}_n = \bigcup_{\omega \in \mathcal{P}_n} \omega.
\]

We call a time \( n \) a free return if there is a parameter interval \( \omega \) belonging to a partition \( \mathcal{P}_n \) such that

\[
\xi_n(\omega) = I_{r,\ell}.
\]

Similarly, if we fix \( b < 1 \), we will have

\[
\xi_n(\omega, b) = I_{r,\ell}.
\]

(In some cases, for technical reasons, these two conditions will have to be replaced by \( I_{r,\ell} \subset \xi_n(\omega) \subset I_{r,\ell}^+ \) or \( I_{r,\ell} \subset \xi_n(\omega, b) \subset I_{r,\ell}^+ \).)

3. Transversality

In this section we prove the transversality condition for maps belonging to the family (1.1).
LEMMA 3.1. The following formula holds:

\[
\partial_a f^n_{a,b}(x) = \sum_{k=0}^{n-1} (f^k_{a,b})'(f^{n-k}_{a,b}(x)) = (f^{n-1}_{a,b})'(f_a(b(x))) \sum_{k=0}^{n-1} \frac{1}{(f^k_{a,b})'(f_a(b(x)))}.
\] (3.1)

Proof. We have

\[
\partial_a f^{n+1}_{a,b}(x) = 1 + f'_a(f^n_{a,b}(x)) \cdot \partial_a f^n_{a,b}(x) \tag{3.2}
\]

(note that \(\partial_a f^0_{a,b}(x) = 0\) and \(\partial_a f^1_{a,b}(x) = 1\)). Using this formula, we prove by induction that

\[
\partial_a f^n_{a,b}(x) = \sum_{k=0}^{n-1} (f^k_{a,b})'(f^{n-k}_{a,b}(x)). \tag{3.3}
\]

If \(n = 0\), then both sides of (3.3) are 0. Assume now that (3.3) holds for some \(n\) and prove it for \(n + 1\) instead:

\[
\partial_a f^{n+1}_{a,b}(x) = 1 + \sum_{k=0}^{n} (f^k_{a,b})'(f^{n-k}_{a,b}(x)) = \sum_{k=0}^{n} (f^k_{a,b})'(f^{(n+1)-k}_{a,b}(x)).
\]

Thus, by induction, (3.3) holds for every \(n\).

Now we have

\[
(f^{n-k-1}_{a,b})'(f_a(b(x))) \cdot (f^k_{a,b})'(f^{n-k}_{a,b}(a)) = (f^{n-1}_{a,b})'(f_a(b(x))).
\]

From this and (3.3) we get

\[
\partial_a f^n_{a,b}(x) = (f^{n-1}_{a,b})'(f_a(b(x))) \sum_{k=0}^{n-1} \frac{1}{(f^k_{a,b})'(f_a(b(x)))} = (f^{n-1}_{a,b})'(f_a(b(c))) \sum_{k=0}^{n-1} \frac{1}{(f^k_{a,b})'(f_a(b(c)))}. \tag*{\square}
\]

We get the following immediate corollary.

COROLLARY 3.2. We have \(\partial_a f_{a,b}(x) \equiv 1\) and if \(n > 0\) then \(\partial_a f^n_{a,b}(x) \geq 1\). Moreover,

\[
\frac{\partial_a \xi_n(a, b)}{(f^{n-1}_{a,b})'(f_a(b(c)))} = \sum_{k=0}^{n-1} \frac{1}{(f^k_{a,b})'(f_a(b(c)))}. \tag{3.4}
\]

so, in particular,

\[
\partial_a \xi_n(a, b) \geq (f^{n-1}_{a,b})'(f_a(b(c))). \tag{3.5}
\]

In a special case, when there is a constant \(C_2\) such that

\[
(f^v_{a,b})'(f_a(b(c))) \geq C_2 e^{v^2/3}, \quad v = 0, 1, 2, \ldots, n - 1, \tag{3.6}
\]
then for all \( \nu \leq n \) we obtain, by combining the inequality with the lower bound (3.5),

\[
1 \leq \frac{\partial_a \xi_n(a, b)}{(f_{a,b}^n)'(f_{a,b}(c))} \leq q_*,
\]

(3.7)

where

\[
q_* = \sum_{i=0}^{\infty} C_2^{-1} e^{-i^{2/3}}.
\]

Remark 3.3. We would like to emphasize the central role that Corollary 3.2 plays in this paper. We prove the estimate (3.6) successively by induction on \( \nu \). We can then conclude that (3.7) holds with \( n \) replaced by \( \nu \) for a given \( \nu \). From this estimate we conclude that the \( x \)- and \( a \)-derivative are comparable at a given time \( \nu \). It is important that we prove the \( x \)-expansion first and then verify the comparison. The constant \( q_* \) will be fixed, that is, it only depends on \( f_{a,0} \).

We will also need the following lemma which can be viewed as a lower bound for the Radon–Nikodym derivative of \( \xi_{\nu}(a, b) \rightarrow \xi_{\mu}(a, b), \nu < \mu \) (with respect to \( a \in \omega \)).

Lemma 3.4. Suppose that \( \omega \) is a parameter interval and \( \nu < \mu \). Assume further that there is a constant \( q' \) such that for all \( t \in \omega \),

\[
(f_{t,b}^{\nu-1})' (f_{t,b}(c)) \geq \frac{1}{q'} \partial_a \xi_{\nu}(t, b).
\]

(3.8)

Then

\[
|\xi_{\mu}(\omega, b)| \geq \frac{1}{q'} \inf_{a \in \omega} (f_{a,b}^{\mu-\nu})' (f_{a,b}(c)) \cdot |\xi_{\nu}(\omega, b)|.
\]

Proof. By Corollary 3.2,

\[
|\xi_{\mu}(\omega, b)| = \int_{\omega} \partial_a \xi_{\mu}(t, b) \, dt \geq \int_{\omega} (f_{t,b}^{\mu-1})' (f_{t,b}(c)) \, dt.
\]

(3.9)

However, by (3.8) we have

\[
(f_{t,b}^{\mu-1})' (f_{t,b}(c)) = (f_{t,b}^{\mu-\nu})' (f_{t,b}(c)) \cdot (f_{t,b}^{\nu-1})' (f_{t,b}(c)) \geq \inf_{a \in \omega} (f_{a,b}^{\mu-\nu})' (f_{a,b}(c)) \cdot \frac{1}{q'} \partial_a \xi_{\nu}(t, b).
\]

Together with (3.9), we get

\[
|\xi_{\mu}(\omega, b)| \geq \frac{1}{q'} \inf_{a \in \omega} (f_{a,b}^{\mu-\nu})' (f_{a,b}(c)) \cdot \int_{\omega} \partial_a \xi_{\nu}(t, b) \, dt
\]

\[
= \frac{1}{q'} \inf_{a \in \omega} (f_{a,b}^{\mu-\nu})' (f_{a,b}(c)) \cdot |\xi_{\nu}(\omega, b)|.
\]

4. The outside expansion

The aim of this section is to prove that we have exponential growth of the derivative for an orbit of a map \( f_{a,b} \) that moves outside an open interval \( I \) containing \( c \), when \( (a, b) \) is a small
perturbation of an MT parameter \((a_0, 1)\). We consider the parameter space \(\mathbb{R}/\mathbb{Z} \times (0, 1)\), and when we speak of a neighborhood of \((a_0, 1)\), we mean its neighborhood in this space.

By \(|x - y|\) we denote the distance between \(x\) and \(y\) on the circle. Since the points \(x\) and \(y\) will be usually close to each other, this makes perfect sense. Denote

\[
\overline{d} = \min_{j \geq 1} |c - f^j_{a_0}(c)|.
\]  

By the definition of an MT parameter, we have \(\overline{d} > 0\).

Since \(f_{a_0}\) has negative Schwarzian derivative, the following lemma follows immediately from Theorem 1.3 of [17] (in a general case one could use also the result of Mañé (see [16])).

**Lemma 4.1.** Let \(I\) be an open interval containing \(c\). Then there exist a neighborhood \(N\) of \((a_0, 1)\), positive constants \(C_3, \kappa_2, \) and an integer \(M_1\) such that if \((a, b) \in N\) then:

(i) if \(x, f_{a,b}(x), \ldots, f^{n-1}_{a,b}(x) \notin I\), then

\[
(f^n_{a,b})'(x) > C_3 e^{\kappa_2 n};
\]

(ii) if \(x, f_{a,b}(x), \ldots, f^{n-1}_{a,b}(x) \notin I\) and \(n \geq M_1\), then

\[
(f^n_{a,b})'(x) > e^{\kappa_2 n}.
\]

**Proof.** By Theorem 1.3 of [17] (or a result of Mañé [16]), there exist \(L > 0\) and \(\kappa' > 0\) such that if \(x, f_{a_0}(x), \ldots, f^{L-1}_{a_0}(x) \notin I\), then \((f^L_{a_0})'(x) > e^{\kappa_2 L}\). Therefore, if \(N\) is a sufficiently small neighborhood of \((a_0, 1)\), then for all \((a, b) \in N\) and \(x\) such that \(x, f_{a,b}(x), \ldots, f^{L-1}_{a,b}(x) \notin I\), we have \((f^L_{a,b})'(x) > e^{\kappa_2 L}\). Since the infimum of \((f^i_{a,b})'(x)\) over \((a, b) \in N, x \notin I\) and \(i = 0, 1, \ldots, L - 1\) is positive, there exists a positive constant \(C_3\) such that (i) holds with \(\kappa_2 = \kappa'_2\). Thus it also holds with \(\kappa_2 = \kappa'_2/2\), and then (ii) holds with any

\[
M_1 > \frac{-\log C_3}{\kappa_2}.
\]

Now we fix a positive constant \(\beta > 0\). It will depend only on the unperturbed map \(f_{a_0}\) and can be chosen as, say \(\frac{1}{100} \min(\widetilde{\kappa}, \kappa_3)\). Here \(\widetilde{\kappa} = (1/\ell) \log \Lambda\), where \(\Lambda\) is the multiplier of the repelling periodic point of the MT point, and \(\kappa_3\) is the Lyapunov exponent in Lemma 4.6.

**Definition 4.2.** Let \(x \in I^{**} = (c - \delta_1, c + \delta_1)\). We say that \(x\) is \(\beta\)-bound to the critical point \(c\) up to time \(p\) for \(f_{a,b}\) if \(p\) is the maximal integer such that

\[
|f^j_{a,b}(x) - f^j_{a,b}(c)| \leq e^{-\beta j} \quad \text{for all } j \leq p.
\]  

(4.2)

Observe that for every \(a, b\) (where \(b \leq 1\)) and every \(x\) we have

\[
f'_{a,b}(x) \leq 4 \quad \text{and} \quad |f''_{a,b}(x)| \leq 4\pi < 13.
\]  

(4.3)

Let us state a version of the bound distortion lemma (see [2, 3]).
LEMMA 4.3. If $\delta_1$ is sufficiently small, then there is a constant $C_4(\delta_1) > 1$, which converges to 1 as $\delta_1 \to 0$, such that for every $x \in I^{**} = (c - \delta_1, c + \delta_1)$ if $x$ is $\beta$-bound to $c$ up to time $p$ for $f_{a_0}$, then

$$\frac{1}{C_4} < \frac{(f^k_{a_0})'(f_{a_0}(x))}{(f^k_{a_0})'(f_{a_0}(c))} < C_4$$

for all $k \leq p$. Moreover, there is a constant $C_5 = C_5(\delta_1) > 0$, which converges to 0 as $\delta_1 \to 0$, such that

$$|f^k_{a_0}(x) - f^k_{a_0}(c)| < C_5$$

for all $k \leq p$.

Proof. Assume that $x$ is bound to $c$ up to time $p$. Now choose $p_1 = \frac{1}{10} \log(1/\delta_1)$. Then by (4.3) we can estimate

$$|f^j_{a_0}(x) - f^j_{a_0}(c)| \leq \delta_1 4^j \leq \delta_1 4^{p_1}$$

if $j \leq p_1$ and

$$|f^j_{a_0}(x) - f^j_{a_0}(c)| \leq e^{-\beta j} \leq e^{-\beta p_1}$$

if $p_1 < j \leq p$. Thus, if $\delta_1$ is sufficiently small then $|f^j_{a_0}(x) - f^j_{a_0}(c)| \leq \overline{d}/2$ and therefore

$$|f^j_{a_0}(x) - c| \geq \frac{\overline{d}}{2}$$

for all $j \leq p$.

This also proves the last statement of the lemma.

We have

$$\frac{(f^k_{a_0})'(f_{a_0}(x))}{(f^k_{a_0})'(f_{a_0}(c))} = \prod_{j=1}^{k} \left(1 + \frac{f^j_{a_0}'(f^j_{a_0}(x)) - f^j_{a_0}'(f^j_{a_0}(c))}{f^j_{a_0}'(f^j_{a_0}(c))}\right)$$

$$\leq \exp \left(\sum_{j=1}^{k} \frac{13|f^j_{a_0}(x) - f^j_{a_0}(c)|}{f^j_{a_0}'(f^j_{a_0}(c))}\right)$$

$$\leq \exp \left\{K_1 \left(\delta_1 p_1 4^{p_1} + \sum_{j=p_1+1}^{k} e^{-\beta j}\right)\right\}.$$  (4.7)

The last sum in the exponential may be empty.

Similarly, using (4.6), we get

$$\frac{(f^k_{a_0})'(f_{a_0}(c))}{(f^k_{a_0})'(f_{a_0}(x))} \leq \exp \left\{K_2 \left(\delta_1 p_1 4^{p_1} + \sum_{j=p_1+1}^{k} e^{-\beta j}\right)\right\}.$$  (4.8)

The sums in (4.7) and (4.8) are bounded by a constant, which only depends on $\delta_1$, so we get (4.4). Moreover, by (4.7) and (4.8), $C_4 > 1$ converges to 1 as $\delta_1 \to 0$. \qed
Set $\tilde{\kappa} = (1/\ell) \log \Lambda$. Then there is a constant $C_6 = C_6(a_0)$ such that

$$(f_a^j)'(f_a^0(c)) \geq C_6 e^{\tilde{\kappa} j}$$

(4.9)

for all $j \geq 1$.

At $c$, the first two derivatives of $f_a$ vanish, but the third one does not. Therefore, there are positive constants $C_7, C_8$ such that for all $a$ sufficiently close to $a_0$,

$$C_7|x - c|^3 < |f_a(x) - f_a(c)| < C_8 |x - c|^3$$

(4.10)

whenever $x \in I^{**}$. If $\delta_1$ is small, the constants $C_7$ and $C_8$ can be made close to each other. Similarly, for some positive constants $C_9', C_{10}'$

$$C_9'(x - c)^2 < f'_a(x) < C_{10}'(x - c)^2$$

(4.11)

whenever $x \in I^{**}$. If instead of $f_a$ we consider $f_{a,b}$ with $b$ sufficiently close to 1, we similarly obtain

$$|x - c|(2 - 2b + C_7(x - c)^2) < |f_{a,b}(x) - f_{a,b}(c)| < |x - c|(2 - 2b + C_8(x - c)^2)$$

(4.12)

and

$$2 - 2b + C_9(x - c)^2 < f'_{a,b}(x) < 2 - 2b + C_{10}(x - c)^2,$$

(4.13)

and we chose $C_9$ and $C_{10}$ so that these estimates are valid for all $b \leq 1$. Moreover, we have

$$|f''_{a,b}(x)| \leq 8\pi^2 |x - c| < 80|x - c|.$$  (4.14)

In the following lemma we estimate the length of the bound period.

**Lemma 4.4.** If $\delta_1$ is sufficiently small, $x$ is $\beta$-bound to $c$ up to time $p$ for $f_a^0$, and $x \in I^{**} \setminus \{c\}$, then

$$p < -\frac{4}{\kappa} \log |x - c|.$$  (4.15)

In the particular case when $x \in I_{\pm r}$ we obtain

$$p \leq \frac{4r}{\kappa}. $$  (4.16)

**Proof.** By Lemma 4.3, we have

$$|f^{P}_{a_0}(x) - f^{P}_{a_0}(c)| > \frac{(f^{P}_{a_0})'(f^{P}_{a_0}(c))}{C_4} |f_{a_0}(x) - f_{a_0}(c)|.$$  

Taking into account (4.9) and (4.10), we get

$$1 > |f^{P}_{a_0}(x) - f^{P}_{a_0}(c)| > \frac{C_6 C_7}{C_4} e^{\tilde{\kappa} p} |x - c|^3.$$  

If $\delta_1$ is small, then $C_4 < 2$, so taking logarithms gives us

$$\log \frac{C_6 C_7}{2} + \tilde{\kappa} p + 3 \log |x - c| < 0.$$
If $\delta_1$ is small, then $-\log |x - c|$ is large, so we get $-\log (C_6 C_7/2) < -\log |x - c|$, and therefore $\bar{\kappa} p < -4 \log |x - c|$.

We need a derivative estimate for an orbit of $f_{a_0}$ that moves completely outside $I^* = (c - \delta, c + \delta)$ or $I^{**} = (c - \delta_1, c + \delta_1)$ but returns to one of these intervals at time $n$.

In the proof of the next lemma we will use the fact that $f_a$ has negative Schwarzian derivative. This result can be generalized to the $C^2$ case (see van Strien [25]).

**Lemma 4.5.** Let $\bar{a}$ be as in (4.1). For every $\delta_1 \in (0, \bar{a}/2)$ and for every $n \geq 1$, if $x$ is such that $f_{a_0}^n(x) \notin I^{**}$ for $j = 0, \ldots, n-1$, and $f_{a_0}^n(x) \in I^{**}$, then $(f_{a_0}^n)'(x) > \bar{a}/2$.

**Proof.** On each side of $x$ there are the two closest preimages of $c$ of order less than $n$: $\eta_1 < x$ and $\eta_2 > x$. Then $f_{a_0}^n$ has positive derivative on $(\eta_1, \eta_2)$ and has negative Schwarzian derivative on that interval. Therefore on one of the intervals $[\eta_1, x)$ and $(x, \eta_2]$ the maximum of the derivative $(f_{a_0}^n)'$ is attained at $x$. We may assume this is the interval $[\eta_1, x]$. Then $f_{a_0}^n(\eta_1) = f_{a_0}^k(c)$ for some $k > 0$, so

$$|f_{a_0}^n(\eta_1) - f_{a_0}^n(x)| \geq \bar{a} - \delta_1 > \bar{a}/2.$$  

By the mean value theorem,

$$|f_{a_0}^n(\eta_1) - f_{a_0}^n(x)| = (f_{a_0}^n)'(t)|\eta_1 - x| \leq (f_{a_0}^n)'(t)$$

for some $t \in (\eta_1, x)$, and thus,

$$(f_{a_0}^n)'(x) \geq (f_{a_0}^n)'(t) > \bar{a}/2.$$  

In the following lemma we consider what we call a free period.

**Lemma 4.6.** Given $\delta_1$ sufficiently small, there exist a neighborhood $N$ of $(a_0, 1)$ in the parameter space and positive constants $C^*$ and $\kappa_3$, such that if $(a, b) \in N$, then if $x, f_{a,b}(x), \ldots, f_{a,b}^{q-1}(x) \notin I^{**}$ and $f_{a,b}(x) \in I^{**}$ then

$$(f_{a,b}^q)'(x) \geq C^* e^{\kappa_3 q}.$$  

(4.17)

Here the constant $C^*$ depends only on the unperturbed map $f_{a_0}$, while $\kappa_3$ depends on $\delta_1$.

**Proof.** By Lemma 4.1, $(f_{a,b}^M)'(x) \geq e^{\kappa_2 M} M$. For a general $q$ write $q = kM_1 + \ell, 0 \leq \ell < M_1$. Choose $\kappa'_3$ so that $e^{\kappa'_3 M_1} \leq 2$.

Since $\ell < M_1$, we have $(f_{a,b}^\ell)'(f_{a,b}^{kM_1}(x)) > \bar{a}/4$ by Lemma 4.5 (here we can extend the estimate to a neighborhood of $N_2$ of $(a_0, 1)$ because we consider only finitely many iterates of the map). Then for $(a, b) \in N = N_1 \cap N_2$,

$$(f_{a,b}^q)'(x) = (f_{a,b}^{kM_1})'(x)(f_{a,b}^\ell)'(f_{a,b}^{kM_1}(x)) \geq e^{\kappa_2 kM_1} \frac{\bar{a}}{4}$$

$$\geq e^{\kappa_2 kM_1} \frac{\bar{a}}{8} e^{\kappa'_3 M_1} \geq e^{\kappa_2 kM_1 + \kappa'_3 \ell},$$

so (4.17) follows with $C^* = \bar{a}/8$ and $\kappa_3 = \min(\kappa_2, \kappa'_3)$. Note that, as required, $C^*$ only depends on the unperturbed map $f_{a_0}$, while $\kappa_3$ depends on $\delta_1$.  

\qed
We will also need an estimate of the derivative during the bound period.

**Lemma 4.7.** Assume that \(9\beta \leq \tilde{\kappa}\). Let \(C^*\) be the constant from Lemma 4.6. Then there is an arbitrarily small \(\delta_1\) such that if \(x\) is \(\beta\)-bound to \(c\) up to time \(p\) for \(fa_0\) and \(x \in I^{**} = (c - \delta_1, c + \delta_1)\) then

\[
(f_{a_0}^p)'(x) > \frac{1}{C^*} e^{(\tilde{\kappa}/4)p}.
\]  

(4.18)

**Proof.** By the mean value theorem, there is a \(y\) between \(f_{a_0}^p(x)\) and \(f_{a_0}^p(c)\) such that

\[
|f_{a_0}^p(x) - f_{a_0}^p(c)| = (f_{a_0}^{p-1})'(y)|f_{a_0}^p(x) - f_{a_0}^p(c)|.
\]

By this, Lemma 4.3 and (4.10), there exists a constant \(K_3\) such that if \(\delta_1\) is sufficiently small then

\[
|f_{a_0}^p(x) - f_{a_0}^p(c)| < K_3 e^{\tilde{\kappa}p} |x - c|^3.
\]

Similarly, since \((f_{a_0}^p)'(x) = f_{a_0}'(x) \cdot (f_{a_0}^{p-1})'(f_{a_0}(x))\), we get by Lemma 4.3 and (4.11) that there exists a constant \(K_4\) such that if \(\delta_1\) is sufficiently small then

\[
(f_{a_0}^p)'(x) > K_4 e^{\tilde{\kappa}p} |x - c|^2.
\]

By the definition of \(p\) we have

\[
|f_{a_0}^{p+1}(x) - f_{a_0}^{p+1}(c)| > e^{-\beta(p+1)},
\]

and therefore for some constant \(K_5\),

\[
|f_{a_0}^p(x) - f_{a_0}^p(c)| > K_5 e^{-\beta p}.
\]

Thus,

\[
K_3 e^{\tilde{\kappa}p} |x - c|^3 > K_5 e^{-\beta p},
\]

so

\[
|x - c|^2 > K_5^{2/3} K_3^{-2/3} e^{(2/3)(-\tilde{\beta} - \tilde{\kappa})p}.
\]

Together with an earlier estimate, this gives us

\[
(f_{a_0}^p)'(x) > K_4 e^{\tilde{\kappa}p} K_5^{2/3} K_3^{-2/3} e^{(2/3)(-\tilde{\beta} - \tilde{\kappa})p} = K_4 K_5^{2/3} K_3^{-2/3} e^{(1/3)(\tilde{\kappa} - 2\beta)p}.
\]

Since \(9\beta \leq \tilde{\kappa}\), we have

\[
\frac{1}{3} (\tilde{\kappa} - 2\beta) > \frac{7}{27} \tilde{\kappa},
\]

and therefore (4.18) holds if

\[
C^* > K_4^{-1} K_5^{-2/3} K_3^{2/3} e^{-(\tilde{\kappa}/108)p(\delta_1)},
\]

(4.19)

where \(p(\delta_1)\) is the bound period associated with \(\delta_1\). Since \(p(\delta_1) \to \infty\) as \(\delta_1 \to 0\), and \(C^*\) is independent of \(\delta_1\), the above inequality holds if \(\delta_1\) is sufficiently small.

**Remark 4.8.** If in (4.18) we replace (on both sides of the inequality) \(p\) by \(p - 1\) or \(p + 1\), then at the right-hand side of in (4.19) there will be one more multiplicative constant. Since
it was irrelevant in the proof what constant is there, Lemma 4.7 still holds with a suitably modified inequality (4.18).

The following lemma is very similar to Lemma 4.1, but the exponent in the estimate does not depend on the size of the neighborhood of \( c \) that we consider. In this lemma we assume that \( \delta_1 \) is sufficiently small (so that the lemmas that we use in the proof hold) but fixed.

**Lemma 4.9.** Let \( I \) be an open symmetric interval around \( c \), whose closure is contained in \( I^{**} \). Fix a sufficiently small neighborhood \( N \) of \((a_0, 1)\) (depending on \( I \)). Then there are constants \( C_{11} > 0 \) and \( \kappa_4 > 0 \), (independent of \( I \)) and an integer \( M \) (depending on \( I \)) such that for \((a, b) \in N\):

(i) if \( x, f_{a,b}(x), \ldots, f_{a,b}^{n-1}(x) \notin I \) and \( f_{a,b}^n(x) \in I^{**} \), then

\[
(f_{a,b}^n)'(x) \geq C_{11} e^{\kappa_4 n};
\]

(ii) if \( x, f_{a,b}(x), \ldots, f_{a,b}^{n-1}(x) \notin I \) and \( n \geq M \), then

\[
(f_{a,b}^n)'(x) \geq e^{\kappa_4 n}.
\]

**Remark.** Note that we state (i) with the weaker assumption \( f_{a,b}^n(x) \in I^{**} \) instead of the more natural \( f_{a,b}^n(x) \in I \). This slightly stronger statement will be used in the proof of (ii).

**Proof.** Let \( 0 = t_0 < t_1 < t_2 < \cdots < t_S < t_{S+1} = n \), where \( t_i \) for \( i \in \{1, 2, \ldots, S\} \) are the times when \( f_{a,b}^t(x) \in I^{**} \setminus I \). We want to estimate

\[
(f_{a,b}^n)'(x) = \prod_{j=0}^{S} (f_{a,b}^{t_{j+1}-t_j})'(f_{a,b}^{t_j}(x)).
\]

The times from \([t_0, t_1)\) form a free period; let \( t_1 - t_0 = q_0 \). Hence, by Lemma 4.6,

\[
(f_{a,b}^{q_0})'(x) \geq C^* e^{\kappa_3 q_0}.
\]

Consider now times from \([t_j, t_{j+1})\), where \( j > 0 \). We can write this interval as a union of a bound period \([t_j, t_j + p_j)\) and a free period \([t_j + p_j, t_{j+1})\), and we write its length as \( t_{j+1} - t_j = p_j + q_j \). For the bound periods \([t_j, t_j + p_j)\) we can use the estimate from Lemma 4.7 if \( N \) is sufficiently small, because by Lemma 4.4 we work only with the finite number of iterates (for \( I \) fixed; this is why \( N \) depends on \( I \)). Although \( p \) may depend on the map that we are using, if \( N \) is sufficiently small, it may only change to \( p \pm 1 \), and then by Remark 4.8 we can still use Lemma 4.7.

Thus, for the bound periods \([t_j, t_j + p_j)\) we get

\[
(f_{a,b}^{p_j})'(f_{a,b}^{t_j}(x)) \geq \frac{1}{C^*} e^{(\kappa_2/4)p_j}
\]

and for the free period, as before, the estimate from Lemma 4.6 gives us

\[
(f_{a,b}^{q_j})'(f_{a,b}^{t_j+p_j}(x)) \geq C^* e^{\kappa_3 q_j}.
\]
Combining these estimates, we get

\[(f^n_{a,b})'(x) \geq C^* e^{k_3 q_0} \prod_{j=1}^{S} \frac{1}{C^*} e^{(\tilde{k}/4)p_j} \cdot C^* e^{k_3 q_j} \geq C^* e^{k'_4 n},\]

with \(k'_4 = \min(k_3, \tilde{k}/4).\) This completes the proof of (i).

Under the assumptions of (ii) instead of (i) we make the same construction and estimates. The only difference is that we do not know that \(f^n_{a,b}(x) \in I^{**},\) so we lose information about the last period. There are two cases.

**Case 1.** \(f^n_{a,b}(x)\) is still in bound state to the last return to \(I^{**}\) at time \(t_S.\) At time \(t_S\) we can use the estimate of (i),

\[(f_{t_S}^{t_S})'(x) \geq C_{11} e^{k'_4 t_S}.

The derivative contribution at time \(t_S\) is

\[f'_{a,b}(f_{t_S}^{t_S}(x)) \geq C'_9 \delta^2.

Then there is a derivative contribution from the time \([t_S + 1, t_S + j],\ j = n - t_S.\) Since \(1 \leq j \leq p_S\) we can use the Collet–Eckmann condition (1.2) and the distortion estimate Lemma 4.3, combined with continuity in \(a\) for \(a \in \mathcal{A},\) and the fact that \(p_S\) is bounded to conclude that, say

\[(f_{j}^{t_S})'(f_{t_S}^{t_S+1}(x)) \geq \frac{1}{2} C_{CE} e^{k_1 j}.

Combining these estimates and using the chain rule, we get that

\[(f^n_{a,b})'(x) \geq C_{11} e^{k'_4 t_S} \cdot C'_9 \delta^2 \cdot \frac{1}{2} C_{CE} e^{(\tilde{k}/4) j},

and since \(n \geq M,\) where \(M\) is allowed to depend on \(\delta,\) this gives estimate (ii) with a suitable \(k''_4 < k'_4.\)

**Case 2.** \(n \geq t_S + p_S.\) In this case we can use (4.20) with \(j = S\) to obtain

\[(f_{p_S}^{p_S})'(f_{a,b}^{t_S}(x)) \geq \frac{1}{C^*} e^{(\tilde{k}/4)p_S}.

Then

\[(f^n_{a,b})'(x) \geq (f_{a,b}^{t_S})'(x)(f_{a,b}^{p_S})'(f_{a,b}^{t_S}(x))((f_{a,b}^{q_S})'(f_{a,b}^{t_S+p_S}(x))),

where \(q_S = n - (t_S + p_S).\) Using Lemma 4.1 and the simple estimate \((f_{a,b})'(x) \geq C'_9 \delta^2\) for \(|x - c| \geq \delta_1,\) we get that

\[(f_{a,b}^{q_S})'(f_{a,b}^{t_S+p_S}(x)) \begin{cases} e^{k_2 q}, & q_S \geq M_1, \\ (C'_9 \delta^2 q_S), & q_S < M_1. \end{cases}

Using that the constants \(\delta_1,\ C'_9,\ k_2\) and \(M_1\) only depend on \(f_{a_0},\) we conclude that (ii) holds with \(k_4 = k''_4\) for \(n \geq M,\) if \(M\) is sufficiently large. The final \(k_4\) is then chosen as \(k_4 = \min(k'_4, k''_4, k'''_4).\)
Remark 4.10. Note that we in this setting will have an analogue of Lemma 4.4 and the estimate
\[ p \leq \frac{4r}{k_4} \]  
holds.

Remark 4.11. We will on several occasions need a distortion estimate in the situation of Lemma 4.9, that is, for orbits located outside of \( I \). We need the estimate for parameter dynamics, that is, we have a parameter interval \( \omega \) in the space of \( a \)-parameters, and we consider \( \xi_j(\omega, b) \) for \( j \) satisfying \( \nu \leq j < \mu = n \), where \( \xi_j(\omega, b) \cap I = \emptyset \) for \( j = \nu, \ldots, n - 1 \) and \( \xi_n(\omega, b) \cap I \neq \emptyset \). Let \( \omega' \subseteq \omega \) be the interval that is mapped onto \( I \).

Then Lemma 4.9(i) implies that
\[ \inf_{a \in \omega'} (f^{n-\nu}_{n-\nu, b}(c)) \geq C_{11} e^{k_4(n-\nu)} \]  
(4.23)

We also assume that (3.6) holds at time \( \nu \), that is, for \( a \in \omega \),
\[ (f^j_{a,b})'(f_{a,b}(c)) \geq C_2 e^{j^{2/3}}, \quad 1 \leq j \leq \nu - 1, \]  
(4.24)

Then by Corollary 3.2,
\[ 1 \leq \frac{\partial_y \xi_\nu(a, b)}{(f^{\nu-1}_{a,b})'(f_{a,b}(c))} \leq q_* \]  
(4.25)

Then we conclude from Lemma 3.4 that
\[ |\xi_n(\omega', b)| \geq \frac{1}{q_*} \inf_{a \in \omega'} (f^{n-\nu}_{n-\nu, b}(c)) \cdot |\xi_\nu(\omega', b)|. \]  
(4.26)

Lemma 4.12. There exists a constant \( C_{12} \) such that in the situation of Remark 4.11, if \( a', a'' \in \omega' \) then
\[ \frac{(f^{n-\nu}_{a',b})'(f^{\nu}_{a',b}(c))}{(f^{n-\nu}_{a'',b})'(f^{\nu}_{a'',b}(c))} \leq \exp \left( C_{12} \frac{|f^{n}_{a',b}(c) - f^{n}_{a'',b}(c)|}{\delta} \right). \]  
(4.27)

Proof. Set \( x_k = f^{\nu+k}_{a',b}(c) \) and \( y_k = f^{\nu+k}_{a'',b}(c) \). Note that \( f^{\prime}_{a,b}(x) \) is independent of \( a \). Therefore,
\[ \log \frac{(f^{n-\nu}_{a',b})'(x_0)}{(f^{n-\nu}_{a'',b})'(y_0)} = \sum_{k=0}^{n-1} (\log f^{\prime}_{a',b}(x_k) - \log f^{\prime}_{a',b}(y_k)) \]  
\[ \leq \sum_{k=0}^{n-1} \left( \frac{|f^{\prime\prime}_{a',b}(\eta_k)|}{f^{\prime}_{a',b}(\eta_k)} \cdot |x_k - y_k| \right) \]  
for some \( \eta_k \) between \( x_k \) and \( y_k \). Since \( \eta_k \notin I^* \) for \( k = 0, \ldots, n - \nu - 1 \), we get, by (4.13) and (4.14),
\[ \frac{|f^{\prime\prime}_{a',b}(\eta_k)|}{f^{\prime}_{a',b}(\eta_k)} < \frac{80}{C_9 \delta}. \]  
(4.28)
Therefore,

$$\log \left( \frac{(f_{a',b}^n)^{n-v}}{(f_{a'',b}^n)^{n-v}}(x_0) \right) \leq \frac{80}{C_9 \delta} \sum_{k=0}^{n-v-1} |x_k - y_k|. \tag{4.29}$$

We have $x_k = \xi_{v+k}(a', b)$ and $y_k = \xi_{v+k}(a'', b)$. Therefore, by Remark 4.11,

$$|x_k - y_k| \leq \frac{q_*}{C_{11}} e^{\kappa_4(n-v-k)} |x_{n-v} - y_{n-v}|.$$

Thus,

$$\sum_{k=0}^{n-v-1} |x_k - y_k| \leq \frac{q_*}{C_{11}} \sum_{m=0}^{\infty} e^{-\kappa_4 m} |x_{n-v} - y_{n-v}| = \frac{q_*}{C_{11}(1 - e^{-\kappa_4})} |x_{n-v} - y_{n-v}|.$$

Together with (4.29), we get

$$\log \left( \frac{(f_{a',b}^n)^{n-v}}{(f_{a'',b}^n)^{n-v}}(x_0) \right) \leq \frac{80q_*}{C_9 C_{11}(1 - e^{-\kappa_4}) \delta} |x_{n-v} - y_{n-v}|.$$

and we have proved (4.27) with

$$C_{12} = \frac{160q_*}{C_9 C_{11}(1 - e^{-\kappa_4})}.$$

Remark 4.13. We note that the distortion in Lemma 4.12 is uniformly bounded since $|f_{a,b}^n(c) - f_{a',b}^n(c)| \leq 2\delta$.

We will need a distortion estimate of the same type as Lemma 4.12 in the situation when we only assume estimates such as (4.23) for all $v < n$ and with another Lyapunov exponent $\kappa_5 > 0$, together with (4.24). This is the case of hyperbolic times in the sense of Alves.

Lemma 4.14. Assume that $\xi_j(\omega, b)$, $j = v, \ldots, n$, is located in $U = S^1 \setminus I^\ast$, and

$$\inf_{a \in \omega} (f_{a,b}^{n-j})'(f_{a,b}^j(c)) \geq C_{11} e^{\kappa_5(n-j)} \text{ for all } j, \ v \leq j < n. \tag{4.30}$$

Furthermore, assume that (4.24) is satisfied. Then

$$\frac{(f_{a',b}^n)^v}{(f_{a'',b}^n)^v} \leq \exp(C_{13} |f_{a',b}^n(c) - f_{a'',b}^n(c)|). \tag{4.31}$$

Here the constant $C_{13}$ can be chosen as $C_{13} = C_{13}' N(f_N, U)/(1 - e^{-\kappa_5})$, where $N(f_N, U)$ is the maximal nonlinearity

$$N(f_N, U) = \sup_{(a,b) \in \mathcal{N}} \max_{x \in U} \frac{|f_{a,b}''(x)|}{f_{a,b}'(x)}.$$

$N(f_N, U)$ depends only on $f_{a_0}$ and hence not on $\delta$, and $C_{13}'$ is a constant that only depends on $f_{a_0}$. 

\[\square\]
5. **Induction**

Recall that the partition of the return interval $I^* = (c - \delta, c + \delta)$ was introduced in §2.

Recall also that we defined $\xi_n(a, b) = f_{a,b}^n(c)$.

The next lemma will be used to start the induction.

**Lemma 5.1.** Assume that $\delta_1$ is sufficiently small and the neighborhood $N$ of $(a_0, 1)$ is sufficiently small. Then there are constants $C_1, C_2, \kappa_6 > 0$ such that for every $\varepsilon = 2^{-j_0}$ sufficiently small, there is a function $b_0(\varepsilon)$ such that for every $b_0(\varepsilon) \leq b < 1$ one can partition $(a_0 - \varepsilon, a_0 - \varepsilon^2)$ into a partition $Q$ of countable number of parameter intervals $\omega$ and an exceptional set $E$ of measure $o(\varepsilon)$, such that for all $\omega \in Q$ there is an $n_0 = n_0(\omega)$ such that for some $(r, \ell)$, with $r \leq \sqrt{n_0}$ (or equivalently $e^{-r} \geq e^{-\sqrt{n_0}}$),

$$I_{r, \ell} \subset \xi_{n_0}(\omega, b) \subset I_{r, \ell}^\perp,$$

and such that for every $a \in \omega$:

1. $$(f_{a,b}^j)'(f_{a,b}(c)) \geq C_2 \varepsilon^{\kappa_6 j} \text{ for } 0 \leq j \leq n_0 - 1;$$
2. $\partial_a f_{a,b}^j(c) \geq C_2 \varepsilon^{\kappa_6 (j-1)} \text{ for } 1 \leq j \leq n_0;$
3. $|\xi_j(a, b) - c| > C_1 \varepsilon^{-\sqrt{j}} \text{ for } 1 \leq j < n_0;$
4. $(f_{a,b}^{n_0-1})'(f_{a,b}(c)) \geq e^{2(n_0-1)^{2/3}};$
5. $|\xi_{n_0}(a, b) - c| \geq e^{-\sqrt{n_0}}.$

The corresponding statement holds also for the interval $(a_0 + \varepsilon^2, a_0 + \varepsilon)$.

**Proof.** We partition $(a_0 - \varepsilon, a_0 - \varepsilon^2)$ into subintervals $\eta_j = (a_0 - 2^{-j}, a_0 - 2^{-j-1}) = (a'_j, a''_j)$, $j = J_0, \ldots, 2J_0 - 1$. The critical point $c$ of unperturbed map $f_{a_0}$ is mapped to a repelling periodic point $P$ in $m$ iterates. Let $U_0$ be a symmetric interval contained in the linearization domain of $P$ such that

$$(f_{a,b}^j)'(x) \geq \lambda_1^j = \Lambda_1 > 1 \text{ for } x \in U_0.$$

Let $\tilde{\eta}_j = (a_0 - 2^{-j}, a_0)$. Then there is a constant $C_{14}$ so that

$$(f_{a,b}^j)'(\xi_m(a, b)) \geq C_{14} \lambda_1^j \text{ for all } a \in \tilde{\eta}_j,$$

as long as $\xi_{m+t}(\tilde{\eta}_j, b) \subset U_0$. We now state a version of Lemma 4.12 which will be used in the startup construction.

**Lemma 5.2.** Suppose that for $a \in \omega$ there is a constant $\check{C} = \frac{1}{2}$, say, such that

$$|\xi_m(\omega', b)| \geq \frac{1}{q*} \inf_{a \in \omega'} (f_{a,b}^{m-v})'(f_{a,b}^v(c)) \cdot |\xi_v(\omega', b)| \geq \frac{1}{2}$$

and

$$(f_{a,b}^j)'(f_{a,b}(c)) \geq \check{C} e^{\delta/4}, \quad 1 \leq j \leq v - 1.$$
Then there is a constant $C_{12}$ such that

$$\frac{(f_{a,b}^{m})'(f_{a',b}^{v}(c))}{(f_{a,b}^{m})'(f_{a',b}^{v}(c))} \leq \exp \left( C_{12} \frac{|f_{a,b}^{m}(c) - f_{a,b}^{n}(c)|}{\delta} \right).$$ (5.3)

We will not give the proof of this lemma since it is identical to that of Lemma 4.12. We conclude that

$$|\xi_{m+i}(\tilde{\eta}_j, b)| \geq \frac{C_{14}}{q_*} \lambda^1 \cdot |\xi_m(\tilde{\eta}_j, b)|$$

and $q_*$ has a uniform control by Corollary 3.2.

We also get a uniform distortion control of $\partial_a f_{a,b}^v(\xi_j(a, b))$, that is, there is a constant $C$ depending only on $a_0$ such that for all $a, a'$ in $\tilde{\eta}_j$,

$$\frac{1}{C} \leq \frac{\partial_a f_{a,b}^v(\xi_j(a, b))}{\partial_a f_{a',b}^v(\xi_j(a', b))} \leq C, \quad v = 1, 2, \ldots,$$ (5.4)

as long as $\xi_{m+v}(\tilde{\eta}_j, b) \subset U_0$.

It follows that there is a first time $L$ such that $\xi_{m+L+1}(\tilde{\eta}_j, b) \not\subset U_0$. We write $\tilde{\eta}_j$ as the disjoint union (except for an endpoint)

$$\tilde{\eta}_j = \eta_j \cup \eta'_j.$$

By (5.4) it follows that $\xi_{m+L}(\eta_j, b)$ and $\xi_{m+L}(\eta'_j, b)$ are comparable within a fixed constant $C_{15}$, which only depends on $f_{a_0}$.

We continue to iterate $\xi_{m+L+i}(\eta_j, b)$ for $i = 1, 2, \ldots$. By Lemmas 4.9, 3.4 and the control of the constant $q_*$ it follows that at the first time $J$ such that $\xi_{m+L+J}(\eta_j, b) \cap I^* \neq \emptyset$,

$$|\xi_{m+L+J}(\tilde{\eta}_j, b)| \geq \frac{C_{11}}{q_*} e^{\kappa_1 J} |\xi_{m+L}(\tilde{\eta}_j, b)|.$$

Then $\kappa_6 = \min(\log \lambda_1, \kappa_4)$ is the required Lyapunov exponent in (a). It follows by Lemmas 4.9(ii), 3.4 and the control of $q_*$ that the time $J$ will be finite. At time $N_0 = m + L + J$, we partition

$$(c - \delta, c + \delta) \cap \xi_{N_0}(\eta_j, b)$$

into preimages $\{\omega\}$ under the map $a \mapsto \xi_{N_0}(a, b)$ of the partition $Q = \{I_{r,i}\}$ and define $n_0 = N_0$ for these $\omega$s. In the special case when $\xi_{N_0}(\eta_j, b)$ only intersects partially an end interval of $Q = \{I_{r,i}\}$, we just keep iterating until we cover complete intervals of $Q$. In other special case when $\xi_{N_0}(\eta_j, b)$ only partially covers an $I_{r,i}$ interval we adjoin the corresponding preimage to the adjacent interval. Simultaneously we delete the part of $\eta_j$ that is mapped to $(c - e^{-\sqrt{n_0}}, c + e^{-\sqrt{n_0}})$. By the uniform distortion of both the $x$-derivative and $a$-derivative which follows from Lemmas 4.9, 4.12 and Corollary 3.2 a proportion of at most $C_{16} e^{-\sqrt{n_0}} / \delta$ of the piece of $\eta_j$ is mapped into $(c - e^{-\sqrt{n_0}}, c + e^{-\sqrt{n_0}})$. Here $C_{16}$ is a constant only depending on $f_{a_0}$. We continue to iterate $\xi_{N_0}(\eta_j, b) \setminus (c - \delta, c + \delta)$, still using Lemmas 4.9, 4.12 and Corollary 3.2. For the new returning interval $\omega$ formed in this way $n_0(\omega) > N_0$ and still only a quantity
proportional to $e^{-\sqrt{n_0}/\delta}$ is deleted. Conclusions (a)–(e) of Lemma 5.1 are immediately verified.

\[ \text{Remark 5.3.} \quad \text{The startup argument is essentially the same as the free period argument in the main induction and the argument in Lemma 4.9 in \S 4. See the main induction below in this section for a more thorough discussion. The only difference is the initial period that is spent close to the repelling periodic point which in some sense replaces the bound period. The expansive behavior close to the repelling periodic point allows us to avoid inessential free returns and gives the initial exclusion ratio of at most $C_1 e^{-\sqrt{n_0}/\delta}$.} \]

Let us now fix $b$, $0 < b_0(\varepsilon) \leq b < 1$. Note that for every positive integer $n$ we have a family $\mathcal{P}_n$ of subintervals of $(a_0 - \varepsilon, a_0 + \varepsilon)$ (as in Lemma 5.1) with pairwise disjoint interiors, such that each element of $\mathcal{P}_{n+1}$ is contained in some element of $\mathcal{P}_n$. In the set of pairs $(n, \omega)$ such that $\omega \in \mathcal{P}_n$ there is a natural structure of a combinatorial tree that goes down with its branches. Pairs $(n, \omega)$ are vertices of this tree; $n$ is the level on which the vertex lies; there is an edge from $(n, \omega)$ to $(n+1, \omega')$ if and only if $\omega' \subset \omega$.

Certain pairs with the property $\xi_n(\omega, b) \subset I^*$ will be called \textit{free return pairs}.

The induction will be separate on every branch of the tree. Fixing the branch results in considering a descending sequence of intervals $\omega_n \in \mathcal{P}_n$. If $(n, \omega_n)$ is a free return pair, then we will call $n$ a free return time. An important feature of the construction is that if $n$ is not a free return time then $\omega_n = \omega_{n-1}$. The main induction step will be from a free return time to the next free return time. The constants $C_2$ and $C_1$ are as in Lemma 5.1. Throughout the entire induction they will stay the same.

Our induction statement is as follows. If $n$ is a free return time and $a \in \omega$, then:

(i) we have

\[
(f_{a,b}^{n-1})'(f_{a,b}(c)) \geq e^{2(n-1)^{2/3}}, \tag{5.5}
\]

(ii) for every $v \in [n_0, n)$,

\[
(f_{a,b}^v)'(f_{a,b}(c)) \geq e^{v^{2/3}}; \tag{5.6}
\]

(iii) for every $v \in [1, n)$,

\[
(f_{a,b}^v)'(f_{a,b}(c)) \geq C_2 e^{v^{2/3}}; \tag{5.7}
\]

(iv) if $v < n$ is also a free return time, then

\[
(f_{a,b}^{n-v})'(f_{a,b}^v(c)) \geq C(\delta) \gg 1; \tag{5.8}
\]

(v) for every $v \in [n_0, n]$,

\[
|\xi_v(a, b) - c| \geq e^{-\sqrt{v}}; \tag{5.9}
\]

(vi) for every $v \in [0, n]$,

\[
|\xi_v(a, b) - c| \geq C_1 e^{-\sqrt{v}}. \tag{5.10}
\]

In \cite{2, 3} statements (v) and (vi) are called the basic assumption (BA).
Remember that $b$ sufficiently close to 1 is fixed. We set $\mathcal{P}_n = \{\omega_b\}$ for $n = 1, 2, \ldots, N_0$. Thus, this is the beginning of every branch. Then we declare $n_0 = n_0(\omega)$ to be the first free return time according to the startup construction. Thus, for every branch we have to start induction by checking that the above conditions are satisfied for $n = n_0(\omega)$.

**Lemma 5.4.** The induction statement conditions (i)–(vi) are satisfied for $n = n_0$.

This is a consequence of the startup construction, Lemma 5.1.

Now we make a small modification to Definition 4.2.

**Definition 5.5.** Let $a'$ be the midpoint of the interval $\omega$ such that

$$\xi_n(\omega, b) \subset I_{r,l}^{+} = I_{r,l-1} \cup I_{r,l} \cup I_{r,l+1}$$

for some $n, r, l$. We define the bound period as the maximal integer $p$ such that for all $j \leq p$, $a \in \omega$, and $x \in \xi_n(\omega, b)$,

$$|f^j_{a,b}(x) - f^j_{a,b}(c)| \leq e^{-4\sqrt{j}}. \quad (5.11)$$

By (4.3) and Lemma 3.1, we get for every $n, a, b, x$,

$$\partial_a f^n_{a,b}(x) \leq \sum_{k=0}^{n-1} 4^k = \frac{4^n - 1}{3} < 4^n. \quad (5.12)$$

In the next several lemmas we will be using the same set of assumptions. We formalize these in the following definition.

**Definition 5.6.** We say that condition (*) is satisfied if:

- $\omega, n, r, l, p$ and $a'$ are as in Definition 5.5,
- conditions (iii), (v) and (vi) of the induction statement hold.

Next we formulate another version of the bound distortion lemma.

**Lemma 5.7.** There is a constant $C_{17}$ such that if condition (*) holds, then

$$\frac{1}{C_{17}} \leq \frac{(f^k_{a,b})'(f_{a,b}(y))}{(f^k_{a,b})'(f_{a,b}(c))} \leq C_{17} \quad (5.13)$$

and

$$\frac{1}{C_{17}} \leq \frac{(f^k_{a,b})'(f_{a,b}(y))}{(f^k_{a',b})'(f_{a',b}(c))} \leq C_{17} \quad (5.14)$$

for every $x \in I_{r,l}$, $y$ between $x$ and $c$, $a \in \omega$, and $k \leq \max(p, n)$. By making $\delta$ sufficiently small, the constant $C_{17} = C_{17}(\delta) > 1$ can be chosen arbitrarily close to 1.

**Proof.** The proof will proceed by induction on $k$. Using (4.3), we get, in the same way as in the proof of Lemma 4.3,

$$\frac{(f^k_{a,b})'(f_{a,b}(y))}{(f^k_{a,b})'(f_{a,b}(c))} \leq \exp\left(\sum_{j=1}^{k} \frac{13|f^j_{a,b}(y) - f^j_{a,b}(c)|}{f^j_{a,b}(f^j_{a,b}(c))}\right). \quad (5.15)$$
Furthermore,
\[ |f_{a,b}^j(y) - f_{a,b}^j(c)| \leq |f_{a,b}^j(x) - f_{a,b}^j(c)| \leq |f_{a,b}^j(x) - f_{a,b}^j(c)| + |f_{a,b}^j(c) - f_{a,b}^j(c)|, \]
and by (5.11) we have
\[ |f_{a,b}^j(x) - f_{a,b}^j(c)| \leq e^{-4\sqrt{J}}. \]  
Thus, we need to estimate \(|f_{a,b}^j(c) - f_{a,b}^j(c)|. Note that by the mean value theorem there is \(a''\) between \(a\) and \(a'\) such that
\[ |f_{a,b}^j(c) - f_{a,b}^j(c)| = \partial_a f_{a,b}^j(c) \cdot |a - a'|. \]  
Note that \(|a - a'|\) can be interpreted as \(|\xi_1(a, b) - \xi_1(a', b)|\). By Lemma 3.4,
\[ |\xi_n(a, b) - \xi_n(a', b)| \geq \frac{1}{q_n} \inf_{\dot{a} \in [a,a']'} (f_{a,b}^{n-1})'(f_{a,b}(c)) \cdot |\xi_1(a, b) - \xi_1(a', b)|. \]  
By induction statement (iii), \((f_{a,b}^{n-1})'(f_{a,b}(c)) \geq C_2 e^{(n-1)2/3}\). We may therefore conclude that \(|a - a'| \leq C_2^{-1} q^e^{-e^{2(n-1)t/3}} \cdot |\xi_n(a, b) - \xi_n(a', b)|\). But by the mean value theorem,
\[ |f_{a,b}^j(x) - f_{a,b}^j(c)| = |f_{a,b}^{j-1}(f_{a,b}(x)) - f_{a,b}^{j-1}(f_{a,b}(c))| \]
\[ = (f_{a,b}^{j-1})'(f_{a,b}(y)) \cdot |f_{a,b}(c) - f_{a,b}(x)|. \]  
However, since \(|\xi_n(a, b) - \xi_n(a', b)| \leq e^{-4\sqrt{J}}\), we have
\[ |f_{a,b}(c) - f_{a,b}(x)| \geq C_7 \cdot |x - c|^3 \geq C_7 e^{2(-r-1)} \cdot e^{-4\sqrt{J}} \cdot |\xi_n(a, b) - \xi_n(a', b)|. \]  
By the basic assumption \(e^{-4\sqrt{J}} \geq C_1 e^{-\sqrt{n}}\). Note also that by Corollary 3.2, \(\partial_a f_{a,b}^j(c)\) is comparable within the multiplicative constant \(q_n\) to \((f_{a,b}^{j-1})'(f_{a,b}(c))\). But this quantity is in itself by induction comparable within a multiplicative constant \(C_{17}\) to \(\inf_{\dot{a} \in [a,a']'} (f_{a,b}^{n-1})'(f_{a,b}(c))\). We use the statement of our result for \(k = j - 1\).

We use (5.18) and note that \(|a - a'|\) can also be written as \(|\xi_1(a, b) - \xi_1(a', b)|\). By Lemma 3.4,
\[ |\xi_n(a, b) - \xi_n(a', b)| \geq \frac{1}{q_n} \inf_{\dot{a} \in [a,a']'} (f_{a,b}^{n-1})'(f_{a,b}(c)). \]  
By combining (5.19), (5.20) and (5.21), we obtain
\[ |f_{a,b}^j(x) - f_{a,b}^j(c)| \]
\[ = |f_{a,b}^{j-1}(f_{a,b}(x)) - f_{a,b}^{j-1}(f_{a,b}(c))| \geq (f_{a,b}^{j-1})'(f_{a,b}(y)) |f_{a,b}(x) - f_{a,b}(c)| \]
\[ \geq \inf_{y \in I_r} (f_{a,b}^{j-1})'(f_{a,b}(y)) |f_{a,b}(c) - f_{a,b}(c)| \]
\[ \geq C_7 e^{-3r} \inf_{y \in I_r} (f_{a,b}^{j-1})'(f_{a,b}(y)) \]
\[ \geq C_7 e^{-2r} \inf_{y \in I_r} (f_{a,b}^{j-1})'(f_{a,b}(y)) |\xi_n(a, b) - \xi_n(a', b)| \].
\[ \geq C_7 e^{-2r} \inf_{y \in T_r^n} (f_{a,b}^{j-1})'(f_{a,b}(y))(\inf_{a \in [a',b]} \partial_a f_{a,b}^n(c)) |\xi_1(a, b) - \xi_1(a', b)| \]
\[ \geq C_7 e^{-2r} \sup_{z \in T_r^n} (f_{a,b}^{j-1})'(f_{a,b}(y))(\inf_{a \in [a',b]} \partial_a f_{a,b}^n(c)) |\xi_j(a, b) - \xi_j(a', b)|. \]

Now \( \sup_{z \in T_r^n} (f_{a,b}^{j-1})'(f_{a,b}(z)) \) and \( \inf_{y \in T_r^n} (f_{a,b}^{j-1})'(f_{a,b}(y)) \) are comparable within constant \( C^{2}_{17} \), by the statement of Lemma 5.7 with \( k = j - 1 \). This is where the inductive step is used. Moreover, by Corollary 3.2 and induction statement (i), we have \( \partial_a f_{a,b}^n(c) \geq q_s^{-1} e^{2(n-1)^2/3} \). Furthermore \( e^{-2r} \geq e^{-2\sqrt{n}} \), by induction statement (v). Combining these estimates, we get

\[ |\xi_j(a, b) - \xi_j(a', b)| \leq \frac{1}{2} |f_{a,b}^j(x) - f_{a,b}^j(c)| \]

since \( n \geq n_0(a) \) and \( n_0(a) \) can be chosen arbitrarily large.

When inserting this estimate in (5.16) we conclude that

\[ |f_{a,b}^j(y) - f_{a,b}^j(c)| \leq 2e^{-4\sqrt{j}}. \quad (5.22) \]

To estimate \( f_{a,b}'(f_{a,b}(c)) \) from below, we use induction statement (vi) and (4.13). We get

\[ f_{a,b}'(f_{a,b}(c)) \geq C_9 C^n_1 e^{-2\sqrt{j}}. \quad (5.23) \]

Putting together (5.15), (5.22) and (5.23), we obtain

\[ \frac{(f_{a,b})'(f_{a,b}(y))}{(f_{a,b})'(f_{a,b}(c))} < \exp \left( \frac{13 \cdot 2}{C_9 C^n_1} \sum_{j=1}^{k} e^{-4\sqrt{j}} \right). \quad (5.24) \]

For the lower bound, we obtain, in a similar way to (5.15),

\[ \frac{(f_{a,b})'(f_{a,b}(c))}{(f_{a,b})'(f_{a,b}(y))} \leq \exp \left( \sum_{j=1}^{k} \frac{13|f_{a,b}^j(y) - f_{a,b}^j(c)|}{(f_{a,b})'(f_{a,b}(y))} \right). \]

Note, however, that

\[ (f_{a,b})'(f_{a,b}(y)) \geq C_9 (f_{a,b}^j(y) - c)^2 \geq C_9 (|c - f_{a,b}(c)| - |f_{a,b}^j - f_{a,b}(y)|)^2, \]

and, using (5.9) and (5.22), we get

\[ f_{a,b}'(f_{a,b}(y)) > C_9 (C_1 e^{-\sqrt{j}} - 2e^{-4\sqrt{j}})^2 \]

whenever \( C_1 e^{-\sqrt{j}} > 2e^{-4\sqrt{j}} \). Now \( C_1 \) is fixed, and thus there is a positive integer \( \tilde{N} \) such that if \( j \geq \tilde{N} \) then \( C_1 e^{-\sqrt{j}} > 2 \times 2e^{-4\sqrt{j}} \), and then

\[ f_{a,b}'(f_{a,b}(y)) > \frac{C_9 C^n_1}{4} e^{-2\sqrt{j}}. \]

By making \( \mathcal{N} \) and \( I^* \) sufficiently small, we can make \( |f_{a,b}^j(c) - f_{a,b}^j(y)| \) smaller than \( C_1 e^{-4\sqrt{j}} \) instead of \( 2e^{-4\sqrt{j}} \), and then we get

\[ f_{a,b}'(f_{a,b}(x)) \geq C_9 C^n_1 K_6 e^{-2\sqrt{j}} \]
for some constant $K_6$ depending only on $a_0$. Thus, in the same way as we obtained (5.24), we get a similar estimate for the reciprocal ratio, but with a different constant. We choose the larger of those constants as $C_{17}$ and we get (5.13). The proof of (5.14) is completely analogous and will be omitted. As for the statement that $C_{17}$ can be chosen arbitrarily close to 1 (but larger than 1), we refer to the argument in Lemma 4.3.

LEMMA 5.8. Assume that condition (*) holds. Then the bound period $p$ in the sense of Definition 5.5 satisfies

$$p \leq 8r^{3/2}.$$ 

Proof. We claim that $p \leq 8r^{3/2}$. Note that $8r^{3/2} \leq 8n^{3/4} < n$. We argue by contradiction. Assume that there is $k > 8r^{3/2}$ such that $f_{a,b}^k(x) - f_{a,b}^k(y)$ is still bound to $f_{a,b}(x) - f_{a,b}(y)$ for all $x \in I_r$ and all $z$ between $x$ and $c$. By the mean value theorem, there is a point $y$ between $x$ and $c$ such that

$$|f_{a,b}^k(x) - f_{a,b}^k(c)| = |f_{a,b}(x) - f_{a,b}(c)| \cdot (f_{a,b}^{k-1})'(f_{a,b}(y)).$$

By Lemma 5.7 and induction statement (iii),

$$(f_{a,b}^{k-1})'(f_{a,b}(y)) \geq \frac{1}{C_{17}} (f_{a,b}^{k-1})'(f_{a,b}(c)) \geq C_2 \frac{C_{17} e^{(k-1)^2/3}}{C_{17} e^{(k-1)^2/3}}.$$

Since $|x - c| \geq e^{-r-1}$, by (4.13) we get

$$|f_{a,b}(x) - f_{a,b}(c)| \geq \frac{C_9}{3} e^{-3r-3}.$$ 

Putting the last three inequalities together, we get

$$|f_{a,b}^k(x) - f_{a,b}^k(c)| \geq \frac{C_2}{C_{17}} e^{(k-1)^2/3} \cdot \frac{C_9}{3} e^{-3r-3}.$$ 

Taking into account (5.22) (which is valid also for $y = x$), we get

$$2 > 2e^{-\sqrt{k}} > \frac{C_2 C_9}{3C_{17}} e^{(k-1)^2/3} e^{-3r-3}.$$ 

Therefore,

$$(k - 1)^{2/3} < 3r - \log K_7$$

where $K_7$ is a constant only depending on $a_0$.

If $\delta$ is sufficiently small, then $\frac{1}{2}r > - \log K_7$, and we get $k^{2/3} < (k - 1)^{2/3} + \frac{2}{3} k^{-1/3} < 4r$. We conclude that $k \leq 8r^{3/2}$ and this gives a contradiction.

Let us prove an elementary lemma about our family.

LEMMA 5.9. For the family of double standard maps, if $0 < |x - c| < \frac{1}{2}$ then

$$f_{a,b}'(x) > \frac{|f_{a,b}(x) - f_{a,b}(c)|}{|x - c|}.$$  (5.25)
Proof. We have \( c = \frac{1}{2} \) and \( f''_{a,b}(t) = -4\pi b \sin(2\pi t) \). Therefore \( f_{a,b} \) is strictly convex in \((c, c + \frac{1}{2})\), and thus for \( x \in (c, c + \frac{1}{2}) \) we get (5.25). Similarly, in \((c - \frac{1}{2}, c)\) the function \( f_{a,b} \) is strictly concave, and (5.25) follows. \( \square \)

**Lemma 5.10.** There exists a positive constant \( C_{18} \) such that if condition (*) holds, then

\[
(f_{a,b}^{p+1})'(x) > C_{18} e^r \cdot e^{-4\sqrt{p+1}}.
\]  

(5.26)

Proof. By Definition 5.5, there exists \( a \in \omega \) such that

\[
|f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| \geq e^{-4\sqrt{p+1}}. \tag{5.27}
\]

We have

\[
|f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| \leq |f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| + |f_{a,b}^{p+1}(c) - f_{a,b}^{p+1}(c)|. \tag{5.28}
\]

By the mean value theorem, there is a point \( y \) between \( x \) and \( c \) such that

\[
|f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| = |f_{a,b}(x) - f_{a,b}(c)| \cdot (f_{a,b}^{p+1})'(f_{a,b}(y)). \tag{5.29}
\]

Now we estimate the second summand in (5.28). As in the proof of Lemma 5.7, we can prove that

\[
|f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| \leq \frac{1}{2} |f_{a,b}^{p+1}(c) - f_{a,b}^{p+1}(x)|.
\]

Therefore

\[
|f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| \geq \frac{1}{2} |f_{a,b}^{p+1}(x) - f_{a,b}^{p+1}(c)| \geq \frac{1}{2} e^{-4\sqrt{p+1}}.
\]

From Lemma 5.7 we get

\[
(f_{a,b}^p)'(f_{a,b}(x)) \geq \frac{1}{C_{17}^2} (f_{a,b}^p)'(f_{a,b}(y)),
\]

so

\[
(f_{a,b}^p)'(f_{a,b}(x)) > \frac{1}{2C_{17}^2} \cdot e^{-4\sqrt{p+1}} \cdot \frac{1}{|f_{a,b}(x) - f_{a,b}(c)|}.
\]

By the chain rule and Lemma 5.9 we get, from this inequality,

\[
(f_{a,b}^{p+1})'(x) > \frac{1}{2C_{17}^2} \cdot e^{-4\sqrt{p+1}} \cdot \frac{1}{|x - c|}.
\]

Since \( x \in I_r \), we have \( |x - c| \leq e^{-r} \), and we get (5.26) with a suitable choice of \( C_{18} \). \( \square \)

Let \((n, \omega)\) be a free return pair. Consider the intervals \( \xi_{n+p+1+s}(\omega, b), s = 0, \ldots, s_0 - 1 \), where \( s_0 \) is the smallest non-negative integer such that

\[
\xi_{n+p+1+s}(\omega, b) \cap I^* \neq \emptyset.
\]

For \( 0 \leq s < s_0 \), we say that \( \xi_{n+p+1+s}(\omega, b) \) is in free orbit and the length of this orbit is \( s_0 \). We also use the notation \( n' = n + p + 1 + s_0 \) and it is our new free return time.

At the first free return there are different cases that can occur.
Case 1. $\Omega_{n'} = \xi_{n'}(\omega, b)$ is completely contained in $I^*$ but does not contain a complete interval $I_{r, \ell}$. Then either $\xi_{n+p+1+s_0}(\omega, b)$ is contained in an interval $I_{r,l}$ or it is contained in the union of two adjacent intervals $I_{r,l} \cup I_{r,l+1}$.

This is called an inessential free return. In this case $\omega \in P_{n'}$, and we just continue to iterate. This also applies if $\Omega_{n'}$ intersects the boundary of $I^*$ but does not contain any of the end intervals.

Case 2. $\Omega_{n'}$ contains at least one of the partition intervals $I_{r, \ell}$. This is the case of an essential free return. We then proceed to define a new partition on a subset of $\omega$ according to the following algorithm.

- We do not include the preimage of $(c - e^{-\sqrt{n}}, c + e^{-\sqrt{n}})$ under $a \mapsto \xi_n(a, b)$ in $\bigcup_{\omega \in P_{n'}} \omega'$, in order that (BA) should be satisfied.

- The intervals $\omega_r, \omega_e$ and $\omega_{r, \ell}$ are defined as the preimages of $I_{r, \ell}$ under $\omega \ni a \mapsto \xi_{n'}(a, b)$. Because of the double covering property of $f_{a,b}$, there could be no, one or two such intervals. These will be new partition intervals of $P_{n'}$. At the two ends of $\omega$ we could have the property that some intervals only partially cover $I_{r, \ell}$. In that case we use the special rule that we adjoin the corresponding subintervals to the adjacent intervals of $P_{n'}$.

- There may be at most three subintervals of $\omega$ (call them $\omega_1$, $\omega_2$ and $\omega_3$) that are mapped outside $I^*$ by $\omega \ni a \mapsto \xi_{n'}(a, b)$. At the beginning of the procedure there are at most two intervals mapped outside, but at later stages, because of the double covering property of $f_{a,b}$, there can be three. In this case these intervals are long, that is, they are not contained in intervals adjacent to the end intervals in the partition of $(c - e^{-r_0}, c + e^{-r_0})$, they are considered to be still free, and the free period continues for these intervals. If one or more of the intervals $\omega_1$, $\omega_2$ or $\omega_3$ are short, rather than long, they are adjoined to their adjacent neighbor.

Let $X_{BA}$ be the set that is mapped to $(c - e^{-\sqrt{n}}, c + e^{-\sqrt{n}})$. Then we define the partition $P_{n'} \mid (\omega \setminus X_{BA})$ as the intervals $\{\omega_r, \ell\}, \{\omega_{r, \ell}\}$ and $\omega_i$, $i = 1, 2, 3$. Some of these intervals may be empty.

Later we will see that deletions because of (BA) do not happen in Case 1, because the interval $\Omega_{n'}$ is too long.

In order to proceed, we need to verify, at least partially, the induction step from time $n$ to time $n'$. Here $n'$ is interpreted as the first free return to $I^*$ after $n$. There may be previous returns $\nu$, where another partition element of $P_{\nu}$ has a free return, while the present parameter interval does not return.

**Lemma 5.11.** Assume induction statements (i)-(vi). Then induction statement conditions (i), (ii), (iii) and (iv) hold for any free return pair $(n', \omega')$, where $n'$ is as above.

**Proof.** Let $\eta$ be the distance from $\xi_n(\omega, b)$ to $c$. Therefore, by induction statement (i) and (4.13),

$$(f_{a,b}^n)'(f_{a,b}(c)) > C_9 \eta^2 e^{2(n-1)^2/3}.$$  

However, by (v), $\eta \geq C_1 e^{-\sqrt{n}}$, so we get

$$(f_{a,b}^n)'(f_{a,b}(c)) > C_9 C_1^2 e^{2(n-1)^2/3} e^{-2\sqrt{n}}. \tag{5.30}$$
After time \( n \) there follows the bound period \( p \), and by Lemma 5.7 and (iii) we get
\[
(f_{a,b}^k)'(f_{a,b}^{n+1}(c)) \geq C_{17}^{-1} (f_{a,b}^k)'(f_{a,b}(c)) \geq C_{17}^{-1} C_2 e^{k^2/3} \tag{5.31}
\]
for all \( k \leq p \). Combining (5.30) and (5.31), we conclude that
\[
(f_{a,b}^{n+k})'(f_{a,b}(c)) = (f_{a,b}^n)'(f_{a,b}(c)) \cdot (f_{a,b}^k)'(f_{a,b}^{n+1}(c)) > C_9 C_1^2 C_{17}^{-1} C_2 e^{2(n-1)^{2/3} - 4\sqrt{n+k^{3/2}}} \tag{5.32}
\]
For \( k \leq p \leq 8r^{3/2} \leq 8n^{3/4} \), we conclude that
\[
(f_{a,b}^{n+k})'(f_{a,b}(c)) \geq e^{(n+k)^{2/3}}
\]
At time \( n + p + 1 \) the bound period has expired and we have for all \( a \in \omega \),
\[
(f_{a,b}^p)'(f_{a,b}^{n+1}(c)) \geq C_19 e^{-8\sqrt{p+1}}, \tag{5.33}
\]
where \( C_19 \) is a constant only depending on \( f_{a_0} \).
For the total derivative we obtain
\[
(f^{n+p})'(f_{a,b}^{n+1}(c)) \geq C_19 e^{2n^{2/3}} e^{-2r} (f_{a,b}^p)'(f_{a,b}^{n-1}(c)) \tag{5.34}
\]
After raising (5.33) to the power \( \frac{2}{3} \) we obtain
\[
(f^{n+p})'(f_{a,b}^{n+1}(c)) \geq C_19^{2/3} e^{2n^{2/3}} (f_{a,b}^p)'(f_{a,b}^{n+1}(c))^{1/3} e^{-8/3\sqrt{p+1}}. \tag{5.35}
\]
Looking at the exponents, we get, using (5.7), the lower bound
\[
2n^{2/3} + \frac{1}{3} p^{2/3} - \frac{8}{3} \sqrt{p+1} \geq 2(n+p)^{2/3} + \frac{1}{10} p^{2/3}.
\]
Here we have used the information from Lemma 5.8, \( p \leq 8n^{3/4} \) and that if \( p \leq 1/100n \) then
\[
2n^{2/3} + \frac{1}{3} p^{2/3} \geq 2(n+p)^{2/3} + \frac{1}{3} p^{2/3}.
\]
Now, if \( k = p + s \) and \( 0 < s \leq s_0 \), then we can use Lemma 4.9(ii). If \( s \geq M \) then
\[
(f_{a,b}^s)'(f_{a,b}^{n+p+1}(c)) \geq e^{k s}.
\]
If \( s < M \) we use Lemma 4.5, which allows a perturbation to \( (a, b) \in N \) with a worse constant \( \bar{d}/4 \) instead of \( \bar{d}/2 \) and we get
\[
(f_{a,b}^s)'(f_{a,b}^{n+p+1}(c)) \geq \bar{d}/4.
\]
Thus, independently of whether \( s \geq M \) or \( s < M \), we have
\[
(f_{a,b}^s)'(f_{a,b}^{n+p+1}(c)) \geq \bar{d}/4 e^{(s-M)k_4}.
\]
Together with (5.32) (where we substitute \( k = p + s \)), we get
\[
(f_{a,b}^{n+k})'(f_{a,b}(c)) = (f_{a,b}^{n+p})'(f_{a,b}(c)) \cdot (f_{a,b}^s)'(f_{a,b}^{n+p+1}(c)) > C_9 C_1^2 C_{17}^{-1} C_2^{7/4} e^{2(n-1)^{2/3} - 4\sqrt{n+1}/10p^{2/3} + (s-M)k_4}.
\]

Note that since the constants $C_3$, $C_1$, $C_{17}$, $C_2$ are absolute constants, $p$ can be made arbitrarily large by making $\delta$ sufficiently small. Doing this, we conclude that induction statements (ii) and (iii) hold for $v$ satisfying $n + p < v < n'$ where $n'$ is the next free return time.

We now turn to verifying (i) at the next free return time $n'$. Using the previous derivative estimates and (i) of Lemma 4.9, we get, after writing $n' = n + p + 1 + q$, that

$$(f_{a,b}^{n'}(\cdot))'(f_{a,b}(c)) \geq e^{\frac{1}{6} (n' - n)^{2/3}}.$$  \hfill (5.36)

**Remark 5.12.** From (5.36) it immediately follows that

$$(f_{a,b}^{n'-1}(\cdot))'(f_{a,b}(c)) \geq (f_{a,b}^{n-1}(\cdot))'(f_{a,b}(c)) \cdot e^{\frac{1}{6} p^3}, \hfill (5.37)$$

which will be used later. We will also later use (5.36).

**Remark 5.13.** Clearly, in Lemma 3.4, $\omega$ can be replaced by any subinterval $\omega' \subset \omega$. If we choose $\mu = n'$ and if $\xi_n(\omega', b) \subset I^*$, and $n + p + 1 \leq v < \mu = n'$, we can use Lemma 4.9(i) to estimate $\inf_{a \in \omega}(f_{a,b}^{n'-v}(\cdot))'(f_{a,b}(c))$ from below by $C_{11}e^{\eta_4(n'-v)}$. Moreover, by Lemma 5.11 we know that induction statement (iii) holds for $v < n'$. Therefore, we conclude from (3.7) that (3.8) holds with $q' = q_*$. We thus get

$$|\xi_{n'}(\omega', b)| \geq \frac{C_{11}}{q_*}e^{\eta_4(n'-v)}|\xi_n(\omega', b)|.$$  \hfill (5.38)

6. The global distortion lemma

**Lemma 6.1.** There exists a constant $C_{13}$, such that if $a$ and $a'$ are two parameter points, so that $a$, $a' \in \omega \in P_n$, where $n$ is a free return time and the induction statement for $n$ (and
all smaller free return times) holds, then

$$\frac{(f_{a,b}^k)'(f_{a,b}(c))}{(f_{a',b}^k)'(f_{a',b}(c))} \leq C_{13}$$

for all \( k \leq n - 1 \).

**Proof.** Let us fix \( k \leq n - 1 \). Set \( t_0 = 1 \) and let \( \{ t_j \}_{j=1}^m \) be the free return times arranged in increasing order. Here \( m \) is defined by the condition \( t_{m-1} < k \leq t_m - 1 \), and we can assume that \( t_m = n \). Observe that for all free returns \( t_j \) there is \( r_j \) such that \( \xi_t(a, b), \xi_t(a', b) \in I_{r_j} \).

Note that \( f_{a,b}'(x) = f_{a',b}'(x) \). Thus, using the mean value theorem, we can write the logarithm of the left-hand side of (6.1) as

$$\log \frac{(f_{a,b}^k)'(f_{a,b}(c))}{(f_{a',b}^k)'(f_{a',b}(c))} = \log \frac{\prod_{j=1}^k f_{a,b}'(\xi_j(a, b))}{\prod_{j=1}^k f_{a',b}'(\xi_j(a', b))}$$

$$\leq \sum_{i=0}^{m-1} \left( \sum_{j=i}^{i+p_i} \left| \frac{f_{a,b}''(\eta_j)}{f_{a,b}'(\eta_j)} \right| |\xi_j(a, b) - \xi_j(a', b)| + \log \frac{(f_{a,b}'(\xi_{i+1} - t_i - p_i - 1)(\xi_{i+1}(a, b)))}{(f_{a,b}'(\xi_{i+1}(a', b)))} \right)$$

for some \( \eta_j \) between \( \xi_j(a, b) \) and \( \xi_j(a', b) \), where \( p_i \) is the corresponding bound time and \( p_0 = -1 \). We will denote the first sum in the parentheses above by \( S_i' \) and the second term in the parentheses by \( S_i'' \). Note that the sum \( S_0' \) is empty.

By (4.13) and (4.14) we get

$$\left| \frac{f_{a,b}''(\eta_j)}{f_{a,b}'(\eta_j)} \right| \leq \frac{80}{C_9|\eta_j - c|}.$$  \hspace{1cm} (6.2)

Set \( \sigma_i = |\xi_i(a, b) - \xi_i(a', b)| \). We claim that the sum \( S_i' \) can be estimated from above by a constant times \( \sigma_i e^{r_i} \).

First we note that by (6.2), the first term of \( S_i' \) can be estimated by \( 80\sigma_i / (C_9e^{-r_i}) \).

For the remaining terms we introduce the reference interval \( \Omega_{t_i} = I_{r_i+1} \) and intervals \( \Omega_{t_i+v} = f_{a,b}'(\Omega_{t_i}), v = 0, 1, 2, \ldots, p_i \). We have

$$\xi_{i+1}(a, b) - \xi_{i+1}(a', b) = (f_{a,b}(\xi_i(a, b)) - f_{a,b}(\xi_i(a', b)))$$

$$+ (f_{a,b}(\xi_i(a', b)) - f_{a,b}(\xi_i(a', b)))$$

$$= f_{a,b}(y)(\xi_i(a, b) - \xi_i(a', b)) + (a - a')$$

for some \( y \) between \( \xi_i(a, b) \) and \( \xi_i(a', b) \). Furthermore, \( |\Omega_{t_i+1}| = f_{a,b}'(y')|\Omega_{t_i}| \) for some \( y' \in \Omega_{t_i} \).

We get

$$\frac{|\xi_{i+1}(a, b) - \xi_{i+1}(a', b)|}{|\Omega_{t_i+1}|} = \frac{f_{a,b}'(y)}{f_{a,b}'(y')} \cdot \frac{\sigma_i}{|\Omega_{t_i}|} \pm \frac{|a - a'|}{f_{a,b}'(y')|\Omega_{t_i}|}.$$  \hspace{1cm} (6.3)

By the mean value theorem,

$$\frac{|a - a'|}{f_{a,b}'(y)\sigma_i} = \frac{1}{f_{a,b}'(y)\sigma_i}$$
for some $a''$ between $a$ and $a'$. By (3.5) and induction statement (iii),
\[
\partial_a \xi_{t_i}(a'', b) \geq (f^{(i-1)}_{a'', b})(f_{a'', b}(c)) \geq C_2 e^{\sqrt{n}}.
\]
By (4.13) and induction statement (v),
\[
f'_{a, b}(y) \geq C_9 C_7^2 e^{-2\sqrt{n}}.
\]
Therefore, we get
\[
\frac{|a - a'|}{f'_{a, b}(y) \cdot \sigma_i} \leq \frac{e}{C_9 C_7^2} \cdot e^{(2\sqrt{n} - (t_i)^{2/3})}.
\]
Since $t_i$ can be made as large as we want (because $t_i \geq n_0$), we get $|a - a'| < f'_{a, b}(y) \sigma_i / 2$.
Therefore, from (6.3) we get
\[
\frac{1}{2} \cdot \frac{1}{f'_{a, b}(y')} \cdot \frac{\sigma_i}{\Omega_i} < \frac{|\xi_{t_i+1}(a, b) - \xi_{t_i+1}(a', b)|}{\Omega_i^{t_i+1}} < 2 \cdot \frac{f'_{a, b}(y)}{f'_{a, b}(y')} \cdot \frac{\sigma_i}{\Omega_i}.
\]
Since $y, y' \in I_{t_i} \cup I_{t_i+1}$, we have $|y - c| \in [e^{-n/2}, e^{-n}]$, and the same holds for $y'$. Therefore, by (4.13), we get
\[
\frac{f'_{a, b}(y)}{f'_{a, b}(y')} \leq \frac{2 - 2b + C_10 e^{-2r}}{2 - 2b + C_9 e^{-2r - 4}}.
\]
The right-hand side above is a weighted average between $(2 - 2b)/(2 - 2b) = 1$ and $(C_10 e^{-2r})/(C_9 e^{-2r - 4}) = C_10 e^4/C_9 > 1$, so it is smaller than $C_10 e^4/C_9$. Since we can switch $y$ and $y'$, we get
\[
\frac{C_9}{C_10 e^4} < \frac{f'_{a, b}(y)}{f'_{a, b}(y')} < \frac{C_10 e^4}{C_9}.
\]
Thus, we get the following inequality with $C_{20} = 2C_10 e^4/C_9$:
\[
C_{20}^{-1} \cdot \frac{\sigma_i}{\Omega_i} \leq \frac{|\xi_{t_i+1}(a, b) - \xi_{t_i+1}(a', b)|}{\Omega_i^{t_i+1}} \leq C_{20} \cdot \frac{\sigma_i}{\Omega_i} \quad (6.4)
\]
Now we want to estimate
\[
\frac{|\xi_{t_i+v}(a, b) - \xi_{t_i+v}(a', b)|}{\Omega_i^{t_i+v}}
\]
from above. The numerator can be estimated as follows:
\[
|\xi_{t_i+v}(a, b) - \xi_{t_i+v}(a', b)| \leq |f^{v-1}_{a, b}(f^{t_i+v}_{a, b}(c)) - f^{v-1}_{a, b}(f^{t_i+v}_{a', b}(c))| + |f^v_{a, b}(f^{t_i}_{a', b}(c)) - f^v_{a', b}(f^{t_i}_{a', b}(c))| \quad (6.5)
\]
By a similar argument to the proof of Lemma 5.8, in particular estimating $|a - a'|$ as in that lemma, we obtain that
\[
|f^v_{a, b}(f^{t_i}_{a', b}(c)) - f^v_{a', b}(f^{t_i}_{a', b}(c))| \leq \frac{1}{2} |\xi_{t_i+v}(a, b) - \xi_{t_i+v}(a', b)|.
\]
Therefore, we get the estimate
\[ |\xi_{t_{i+1}}(a, b) - \xi_{t_i}(a', b)| \leq 2|f^{v-1}_{a,b}(f_{a,b}^{t_{i+1}}(c)) - f^{v-1}_{a,b}(f_{a,b}^{t_i}(c))| \]
\[ = 2(f^{v-1}_{a,b}(y))|\xi_{t_{i+1}}(a, b) - \xi_{t_i}(a', b)|, \]
where \( y \) is between \( \xi_{t_{i+1}}(a, b) \) and \( \xi_{t_i}(a', b) \) (using the mean value theorem). Again by the same theorem there is \( y'' \in \Omega_{t_{i+1}} \) such that
\[ |\Omega_{t_{i+1}}| = (f^{v-1}_{a,b}(y''))|\Omega_{t_i}|. \]

By Lemma 5.7, \( (f^{v-1}_{a,b}(y))/(f^{v-1}_{a,b}(y'')) \leq C^2_1 \), so we get
\[ \frac{|\xi_{t_{i+1}}(a, b) - \xi_{t_i}(a', b)|}{|\Omega_{t_{i+1}}|} \leq 2C^2_1 \frac{|\xi_{t_i+1}(a, b) - \xi_{t_i}(a', b)|}{|\Omega_{t_i}|}. \]

Let us consider the interval \( \omega_i \in \mathcal{P}_i \) containing \( \omega \) and denote its midpoint by \( \hat{a}_i \). Then by (5.11),
\[ |\xi_{t_{i+1}}(\hat{a}, b) - \xi_v(\hat{a}_i, b)| \leq e^{-4\sqrt{v}} \]
for all \( \hat{a} \in \omega_i \) and \( v \leq p_i \).

We claim that for all \( \hat{a} \in \omega_i \) and \( v \leq p_i \) we have
\[ |\xi_{t_{i+1}}(\hat{a}, b) - c| \geq \frac{1}{2}|\xi_v(\hat{a}_i, b) - c|. \]

There is an integer \( v_0 \) such that
\[ \frac{1}{2} \cdot C_1 e^{-\sqrt{v}} \geq e^{-4\sqrt{v}} \]
for all \( v \geq v_0 \). Note that \( v_0 \) depends only on \( C_1 \), which is independent of \( \delta \). Therefore, we may assume that \( \delta \) is so small that
\[ 2\delta \cdot 4^{v_0} \leq \frac{1}{2} \cdot C_1 e^{-\sqrt{v_0}}. \]

Moreover, by induction statement (v),
\[ |\xi_v(\hat{a}_i, b) - c| \geq C_1 e^{-\sqrt{v}}. \]

Consider \( v \leq p_i \). If \( v \geq v_0 \), then by (6.8), (6.10) and (6.12), we get
\[ |\xi_{t_{i+1}}(\hat{a}, b) - \xi_v(\hat{a}_i, b)| \leq \frac{1}{2}|\xi_v(\hat{a}_i, b) - c|. \]

Therefore,
\[ |\xi_{t_{i+1}}(\hat{a}, b) - c| \geq |\xi_v(\hat{a}_i, b) - c| - |\xi_{t_{i+1}}(\hat{a}, b) - \xi_v(\hat{a}_i, b)| \geq \frac{1}{2}|\xi_v(\hat{a}_i, b) - c| \]
and (6.9) follows.

If \( v < v_0 \) then by (4.3) and (5.12),
\[ |\xi_{t_{i+1}}(\hat{a}, b) - \xi_v(\hat{a}_i, b)| \leq |\xi_{t_{i+1}}(\hat{a}, b) - \xi_v(\hat{a}_i, b)| + |\xi_v(\hat{a}, b) - \xi_v(\hat{a}_i, b)| \leq 4^{v}|\xi_v(\hat{a}, b) - c| + 4^{v}|\hat{a} - \hat{a}_i| \leq 4^{v}(\delta + |\omega_i|). \]
By Lemma 5.1(b) for \( j = n_0 \) and by making \( n_0 \) sufficiently large, we get \( \partial_a \xi_j (a, b) \geq 1 \).

Therefore,
\[
|\omega| \leq |\xi_{n_0} (\omega, b)| \leq \delta.
\]

Thus, \(|\omega_i| \leq \delta\), and we get
\[
|\xi_{\nu_i} (\nu_i, b) - \xi_{\nu_i} (\nu_i, b)| \leq 2\delta \cdot 4^{\nu}.
\]

Together with (6.11) and (6.12) in this case we also get (6.13), and (6.9) follows.

Now for each \( \nu \) we choose \( \tilde{a}_\nu \) between \( a \) and \( a' \), so that \( \tilde{a}_\nu (\nu_i, b) = \eta_{\nu_i} \). Thus, by (6.9) and (6.12),
\[
|\eta_{\nu_i} - c| = |\xi_{\nu_i} (\tilde{a}_\nu) - c| \geq \frac{1}{2} |\xi_{\nu_i} (\tilde{a}_\nu) - c| \geq \frac{1}{2} C_1 e^{-\sqrt{\nu}}.
\]

By (6.2) we have
\[
\sum_{j=t_i+1}^{t_i+p_i} \frac{f''_{a,b} (\eta_j)}{f'_{a,b} (\eta_j)} \left| \xi_j (a, b) - \xi_j (a', b) \right| \leq \sum_{\nu=1}^{p_i} \frac{80}{C_9} \frac{|\Omega_{\nu_i}|}{|\eta_{\nu_i} - c|} \cdot \frac{|\xi_{\nu_i} (a, b) - \xi_{\nu_i} (a', b)|}{|\Omega_{\nu_i}|}.
\]

By the definition of bound periods and the definition of \( \Omega_{\nu_i} \), we have
\[
|\Omega_{\nu_i}| \leq e^{-4\sqrt{\nu}}.
\]

Moreover,
\[
|\Omega_{\nu_i}| = e^{-r_i} - e^{-r_i-2}.
\]

Substituting those two inequalities, (6.14), (6.7) and (6.4) into the right-hand side of (6.15), we get
\[
\sum_{j=t_i+1}^{t_i+p_i} \frac{f''_{a,b} (\eta_j)}{f'_{a,b} (\eta_j)} \left| \xi_j (a, b) - \xi_j (a', b) \right| \leq \sum_{\nu=1}^{p_i} C_{21} \cdot \frac{e^{-4\sqrt{\nu}}}{e^{-\sqrt{\nu}}} \cdot \frac{\sigma_i}{e^{-r_i}}
\]

for some constant \( C_{21} \). This implies that there is a constant \( C_{22} \) such that
\[
\sum_{j=t_i+1}^{t_i+p_i} \frac{f''_{a,b} (\eta_j)}{f'_{a,b} (\eta_j)} \left| \xi_j (a, b) - \xi_j (a', b) \right| \leq C_{22} \frac{\sigma_i}{e^{-r_i}}.
\]

Together with the estimate on the first term of \( S'_i \), that we obtained long ago, we get a constant \( C_{23} \) such that
\[
S'_i \leq C_{23} \frac{\sigma_i}{e^{-r_i}}.
\]

(6.16)

Note that \( C_{23} \) depends on \( \kappa_2 \), but not on \( \delta \).

To estimate \( S''_i \), we use Lemma 4.12, and immediately get
\[
S''_i \leq C_{12} \frac{\sigma_i}{\delta}.
\]
However, $\delta > e^{-r_i+1}$, so

$$S_i'' \leq C_{12} \frac{\sigma_i+1}{e^{-r_i+1}}. \tag{6.17}$$

This estimate also applies to $S_0''$.

By Lemma 3.4 applied to a subinterval $\omega' = [a, a']$ (or $[a', a]$) of $\omega$ (made possible by Remark 5.13) and (5.36) (see Remark 5.12), we get

$$\sigma_i+1 \geq \frac{1}{q_n} \inf_{a \in \omega'} (f_{a,b}^{t_i+1-t_i})(f_{a,b}^{t_i}(c)) \cdot \sigma_i \geq C_{11} C_{18} e^{(p_i^{2/3} - 4\sqrt{p_i+1})} \cdot \sigma_i.$$

As we already noticed in the proof of Lemma 5.11, by taking $\delta$ sufficiently small we can make $p_i$ as large as we need and we may assume that

$$\frac{C_{11} C_{18}}{q_n} \exp\{p_i^{2/3} - 4\sqrt{p_i+1}\} \geq 2,$$

and therefore we get

$$\sigma_i+1 \geq 2\sigma_i. \tag{6.18}$$

We are now ready to estimate the logarithm of the left-hand side of (6.1), which is less than or equal to $\sum_{i=0}^{m-1} (S_i' + S_i'')$. By (6.16) and (6.17), we get

$$\sum_{i=0}^{m-1} (S_i' + S_i'') \leq (C_{23} + C_{12}) \sum_{i=0}^{m} \frac{\sigma_i}{e^{-r_i}}.$$

Rearrange the sum $\sum_{i=0}^{m} \sigma_i/e^{-r_i}$ and group it according to the values of $r_i$. Set $W_k = \{i \in [1, m] : r_i = k\}$. Consider $k$ such that $W_k$ is non-empty. Then we can write $W_k = \{i_s < i_{s-1} < \cdots < i_0\}$, and by (6.18) we have $\sigma_i \leq \sigma_i/2^j$. Thus,

$$\sum_{i \in W_k} \frac{\sigma_i}{e^{-r_i}} \leq 2 \frac{\sigma_{\mu_k}}{e^{-k}},$$

where $\mu_k$ is the largest element of $W_k$. However, $\sigma_{\mu_k}$ is the length of an interval which is contained in the union of three subintervals of $I_k$, and the length of each of those subintervals is $|I_k|/k^2$. Moreover, $|I_k| < e^{-k}$. Thus,

$$\sum_{i \in W_k} \frac{\sigma_i}{e^{-r_i}} \leq \frac{6}{k^2}. \tag{6.19}$$

If $W_k$ is empty, then of course (6.19) also holds. In this way we get

$$\sum_{i=0}^{m-1} (S_i' + S_i'') \leq 6(C_{23} + C_{12}) \sum_{k=1}^{\infty} \frac{1}{k^2}.$$

The right-hand side of the above inequality is finite, so we can denote its exponential by $C_{13}$ and then (6.1) holds.

**Lemma 6.2.** There exists a constant $C_{24}$, such that if $a$ and $a'$ are two parameter points, so that $a, a' \in \omega \in \mathcal{P}_n$, where $n$ is a free return time and the induction statement for $n$ (and
all smaller free return times) holds, then

$$\frac{\partial_a f_{a,b}^k(c)}{\partial_a f_{a,b}^k(c)} \leq C_{24}$$

for all $k \leq n$.

**Proof.** The lemma follows immediately from Lemma 6.1, Corollary 3.2 and induction statement (iii).

### 7. Part I of the proof of Theorem A

In this section we prove a proposition which is an essential part of the proof of Theorem A and is stated as follows.

**Proposition 7.1.** Let $a = a_0$ be an MT parameter for $f_a$ and let $\varepsilon > 0$ be given. There exist a function $\eta(\varepsilon) \rightarrow 0$ and a function $b_0(\varepsilon) \rightarrow 1$ as $\varepsilon \rightarrow 0$ such that if $b_0(\varepsilon) < b < 1$, if $\omega_0$ is a parameter interval such that

$$\omega_0 \subset (a_0 - \varepsilon, a_0 - \varepsilon^2) \cup (a_0 + \varepsilon^2, a_0 + \varepsilon),$$

such that $I_{r,\ell} \subset \xi_n_0(\omega_0, b) \subset I_{r,\ell}^+$ and such that induction assumptions (i)–(vi) are satisfied for $n = n_0$, then there is a set $\tilde{E}_b \subset \omega_0$ such that $|\tilde{E}_b| \geq (1 - \eta(\varepsilon))|\omega_0|$, $C = C(a_0)$ and $\hat{\kappa} = \hat{\kappa}(a_0) > 0$ so that

$$(f_{a,b}^n)'(f_{a,b}(c)) \geq C e^{\hat{\kappa} n} \quad \text{for all } n \geq 0, \quad \text{for all } a \in \tilde{E}_b.$$  

Note that the assumptions of Proposition 7.1 are satisfied by Lemma 5.1.

This, together with Proposition 8.1 in §8, immediately leads to the following corollary.

**Corollary 7.2.** The set $E$ of parameters for which the double standard map is uniformly expanding accumulates on the MT points $(a_0, 1)$ in the parameter space.

However, we will need a more general formulation of the propositions given above in order to prove Theorem A.

The proofs will be based on the induction formulated in §5. In the critical case $b = 1$, which we are not treating in detail, the remaining parameter set is of positive measure, while in the non-critical case $b < 1$ the remaining parameter set is a finite union of intervals.

We first discuss the parameter deletion due to the (BA) assumption.

If $n$ is a free essential return time for a partition element $\omega = (a, a')$ of a partition $\mathcal{P}_{n''}$, let $n''$ be the essential free return immediately before $n$.

At each time we may have to omit a fraction of the parameter interval because of (BA). Assume that the previous free return occurred in the interval $I_{r',\ell'}$. Its length is $c/r'^{n/2}|I_{r',\ell'}|$, $1 \leq c \leq 3$. By the (BA) assumption applied to time $n''$, we have

$$e^{-r''} \geq e^{-\sqrt{n''}}.$$
Observe that the minimal length of \( n - n'' \) has a lower bound \( n - n'' \geq C \log(1/\delta) \), where \( C \) is a constant only depending on \( f_{a_0} \). Note also that \( r'' \leq \sqrt{n} \).

During the bound period the interval \( \mathcal{K}_{r''+1} = (c, c + e^{-r''-1}) \) of size \( e^{-r''-1} \) is increased to size \( e^{-\sqrt{p''+1}} \), where \( p'' \leq 8(r'')^{3/2} \) by Lemma 5.8. Our present interval is of length \( c'/r''|I_n| \), \( 1 \leq c' \leq 3 \).

For \( a = a' \) the size of \( f_{a',b}(\mathcal{K}_{r''+1}) \) can be estimated by formula (4.12) as follows:

\[
|x - c|(2 - 2b + C_9(x - c)^2) \leq |f_{a',b}(x) - f_{a',b}(c)| \leq |x - c|(2 - 2b + C_{10}(x - c)^2).
\]

By inserting \( x = c + e^{-r''-1} \) we obtain an estimate for \( |f_{a,b}(\mathcal{K}_{r''+1})| \) as follows:

\[
e^{-r''-1}(2 - 2b + C_7e^{-2r''-2}) \leq |f_{a,b}(\mathcal{K}_{r''+1})| \leq e^{-r''-1}(2 - 2b + C_8e^{-2r''-2}). \tag{7.3}
\]

For the image of \( \omega \) at time \( n'' + 1 \) we obtain the estimate

\[
|\xi_{n''+1}(a, b) - \xi_{n''+1}(a', b)| = f'_{a,b}(y) \cdot |\xi_{n''}(a, b) - \xi_{n''}(a', b)| \pm |a - a'|. \tag{7.4}
\]

Here \( y \in I_r \) so it follows from (4.13) that \( |a - a'| \) can be estimated by the first term as in the estimate of (6.3) and we obtain

\[
2 - 2b + C_9e^{-2r''-2} < f'_{a,b}(y) < 2 - 2b + C_{10}e^{-2r''}.
\]

By the definition of a free return we also have the estimate

\[
\frac{1}{r''/2}e^{-r''} \leq |\xi_{n''}(a, b) - \xi_{n''}(a', b)| \leq \frac{3}{r''/2}e^{-r''}.
\]

By Lemma 5.7 (the bound distortion lemma) and comparison with the orbit of \( \mathcal{K}_{r''} \) the size of \( |\xi_{n''+p''+1}(a, b) - \xi_{n''+p''+1}(a', b)| \) has the lower bound

\[
\frac{1}{C_{17}} \cdot \frac{1}{r''/2}e^{-4\sqrt{p''+1}} \geq \frac{1}{C_{17}} \cdot \frac{1}{r''/2}e^{-(\sqrt{8(r'')^{3/2}})} \geq \frac{1}{C_{17}}e^{-8^{3/2}n^{3/8}}.
\]

We have again used that \( \delta \) may be chosen arbitrarily small. Using (6.18) and Lemmas 4.9 and 3.4, it follows that the relative fraction to be deleted is at most

\[
C_{17}^{-1}C_{11}^{-1} \frac{1}{q_0} e^{-8^{3/2}n^{3/8}} < e^{-1/2\sqrt{n}} \tag{7.5},
\]

since \( n \geq n_0 \); at each time \( n \) we may in principle to have to do such a deletion. The remaining fraction of the parameter interval can then be estimated from below as

\[
\geq \prod_{n = N_0}^{\infty} (1 - e^{-1/2\sqrt{n}}). \tag{7.6}
\]

Note that this is arbitrarily close to 1 as \( N_0(\varepsilon) \rightarrow \infty \) as \( \varepsilon \rightarrow 0 \).

Outline of proof of Proposition 7.1. The proof of Proposition 7.1 is based on induction. Note that the Cantor set construction can be stopped at a finite stage \( \hat{N} \), which is defined by the relation

\[
2 - 2b \geq C_9e^{-2\sqrt{\hat{N}}}.
\]
After this time the term \(2 - 2b\) of equation (4.12) dominates in the derivative and we conclude that for all \(a \in \hat{E}_b\) there is a constant \(C > 0\) such that
\[
(f^n_{a,b})'(f_{a,b}(c)) \geq Ce^{\kappa n} \quad \text{for all } n \geq 0.
\] (7.7)

A more general result with a more detailed proof is given in Proposition 8.1.

Outline of the proof of Proposition 1.1. We proceed as in the proof of Theorem A. In this case the time \(\hat{N}\), after which the linear term \(2 - 2b\) dominates in the derivative, does not exist and the induction proceeds to infinite time. We now have to use the large deviation argument of [3]. The main idea is that you delete parameters for which the critical orbits spend too large fractions of the time recovering the derivative loss from returns to \((c - \delta^2, c + \delta^2)\). However, an estimate similar to (7.6) is still valid. We do not give the full details.

8. Part II of the proof of Theorem A: the uniform expansion

In this section we consider \(b < 1\), and we construct a non-empty union of open intervals \(\hat{E}_b \supset \tilde{E}_b\) so that for \(a \in \hat{E}_b\) there is an integer \(N\) such that \(f^N_{a,b}\) is uniformly expanding. This is formulated in Proposition 8.1. The set \(\hat{E}_b\) is obtained by stopping the construction of the parameter set \(\tilde{E}_b\) of Proposition 7.1 at a finite stage.

Let us outline the main idea of the proof of the uniform expansion. We will heavily use that the fact that \(d = 2 - 2b > 0\), that is, that the inflexion point is non-critical. In the case where the starting point \(x\) is outside the return interval \(I^*\) we can use (i) of Lemma 4.9 to conclude that if \(x, f_{a,b}(x), \ldots, f_{a,b}^{n-1}(x) \notin I^*, \text{ and } f_{a,b}(x) \in I^*\) then
\[
(f^n_{a,b})'(x) \geq C_{11}e^{\kappa x n}.
\]

Here it is important that the constant \(C_{11}\) does not depend on \(\delta\).

At the return time \(n\) we have a derivative loss but this derivative loss is compensated during the bound period by Lemma 4.7. Since \(p \to \infty\) as \(\delta \to 0\), we can make the factor \(e^{p^2/3}\) compensate \(C_2/C^*\) by making \(\delta\) sufficiently small. We also use that the derivative of \(f_{a,b}\) is bounded below by \(f'_{a,b}(\frac{1}{2}) = 2 - 2b\), and we will also denote this number by \(d\).

We state this result as follows.

PROPOSITION 8.1. Let \(a = a_0\) be an MT parameter. Then if \(b_0 = b_0(a_0) < 1\) is sufficiently close to 1 then for all \(b \in (b_0, 1)\) there is a set \(\hat{E}_b\) which is a finite union of intervals \(\{\omega_j\}_{j=0}^{J_0}\) such that, for \(a \in \omega_j\), there is an integer \(M_j\) such that for all \(x \in \mathbb{T}\),
\[
(f_{a,b}^{M_j})'(x) \geq \lambda_j > 1.
\] (8.1)

Proof. The proof is initially the same as the proof of Proposition 7.1.

As before, we carry out the construction only until time \(\hat{N}\). Here \(\hat{N}\) is the smallest integer satisfying
\[
e^{-\sqrt{\hat{N}}} \leq d.
\]

At time \(\hat{N}\) we have a partition \(\mathcal{P}_{\hat{N}}\) consisting of finitely many intervals \(\{\omega_j\}_{j=1}^{M_{\hat{N}}}.\)
We now aim to prove that the hyperbolicity statement (8.1) is true.

We first recall the two outside expansion statements of Lemma 4.9. Suppose that \((a, b) \in \mathcal{N}\) and chose \(I = I^* = (c - \delta, c + \delta)\) in that lemma. Then the following assertions hold.

1. If \(x, f_{a,b}x, \ldots, f_{a,b}^{n-1}x \notin I^*\) and \(f_{a,b}^n x \in I^*\), then
   \[
   (f_{a,b})'(x) \geq C_{11} e^{\kappa_4 n}.
   \]

2. There is an integer \(M\) such that if \(x, f_{a,b}x, \ldots, f_{a,b}^{M-1}x \notin I^*\) then
   \[
   (f_{a,b}^M)'(x) \geq e^{\kappa_4 M}.
   \]

Let us define \(R_0\) as the smallest integer satisfying
\[
e^{-2R_0} \leq e^{-\sqrt{N}},\]
that is, \(R_0\) corresponds to the \(r\) where the square term in the expression for the derivative is of the same size as the constant term \(d = 2 - 2b\). The bound period \(p(x), x \in (c - e^{-R_0}, c + e^{-R_0})\), is chosen to be the infimum of the bound period for \(y \in I_{\pm R_0}\).

We also know by (5.6) and Lemma 5.7 that
\[
(f_{a,b}^p)'(x) \geq \frac{1}{C_{17}} e^{p^2/3}, \quad x \in I_{\pm r}.
\]
and we also have that
\[
(f_{a,b}^p)'(x) \geq \frac{1}{C_{17}} e^{p^2/3}, \quad x \in (c - e^{-R_0}, c + e^{-R_0}).
\]
Introducing \(\kappa_7\) as
\[
\kappa_7 = \frac{1}{2} \min_{r \leq |r| \leq R_0} \min_{x \in I_r} \frac{1}{p(x)^{1/3}},
\]
we can in all cases write these estimates as
\[
(f_{a,b}^p)'(x) \geq e^{\kappa_7 p}.
\]

The factor \(\frac{1}{2}\) is here used to absorb the constant \(C_{17}\).

Let us in the following use the notation \(\hat{I}_{R_0}\) for the union of \((c - e^{-R_0-1}, c + e^{-R_0-1})\) and the previously defined \(I_{-R_0}\) and \(I_{R_0}\). The idea is that the derivative recovery has the same estimate for these three (original) intervals since \((f_{a,b})'(x) \sim d = 2 - 2b\) in \(\hat{I}_{R_0}\) and the bound period is defined in terms of \(I_{R_0}\).

Divide the set \(\mathbb{T} \setminus I^*\) into several pieces.

We first consider the set
\[
X_M = \{x : x, f_{a,b}x, \ldots, f_{a,b}^M x \notin I^*\}.
\]
For \(x \in X_M\), hyperbolicity is valid by Lemma 4.9(ii):
\[
(f_{a,b})'(x) \geq e^{\kappa_4 M}.
\]

We also introduce the sets
\[
X_k = \{x : x, \ldots, f_{a,b}^{k-1} x \notin I^* \text{ but } f_{a,b}^k x \in I^*\}, \quad 1 \leq k \leq M - 1.
\]
Pick a $k \geq 1$. Now write the set

$$X_k = \bigcup_{r_\delta \leq |r| < R_0} X_{k,r},$$

where $X_{k,r} = \{ x \in X_k : f_{a,b}^k x \in I_r, |r| \leq |r| < R_0 \}$ and

$$X_{k, \pm R_0} = \{ x \in X_k : f_{a,b}^k x \in (c - e^{-R_0}, c + e^{-R_0}) \}.$$

Then we know that for $x \in X_{k,r},$

$$(f_{a,b}^{k+p})'(x) \geq C_{11} e^{\kappa_4} e^{\kappa_7 p} \geq e^{\kappa_8(k+p)},$$

where $\kappa_8 = \min(\kappa_4, \kappa_7/2)$.

Here we have used the fact that also for the minimal possible $p$ the factor $e^{\kappa_7/2p}$ always compensates the constant $C_{11}$ of Lemma 4.9, and this constant is independent of $\delta$.

Hence, we know that the entire set $\mathbb{T}$ can be written as a disjoint union of sets $\{Y_j\}_{j=1}^J$ so that for some $\kappa_9$ and all $x \in Y_j,$

$$(f_{a,b}^{n_{j_0}+\cdots+n_{j_0}})'(x) \geq e^{\kappa_9 n_{j_0}}.$$  

We start with an $x \in Y_{j_0}$. After $n_{j_0}$ steps we will end up in $Y_{j_1}$ and after another $n_{j_1}$ steps we will end up in $Y_{j_2}$, and so on. The total time will be $n_{j_0} + n_{j_1} + n_{j_2} + \cdots + n_{j_s}$ and

$$(f_{a,b}^{n_{j_0}+\cdots+n_{j_0}})'(x) \geq e^{\kappa_9(n_{j_0}+\cdots+n_{j_0})},$$

where

$$n_{j_s} + \cdots + n_{j_0} = \sum_{i=1}^{m} k_i n_i.$$  

Let $n_{\text{max}} = \max_{1 \leq j \leq J} n_j$ and pick an integer $N$ very large so that

$$e^{\kappa_9 N} \cdot d_1^n_{\text{max}} \geq e^{\kappa_{10} N}.$$  \hspace{1cm} (8.3)  

Here $d_1 = 1/B$, where $B = 4 \geq \max_{x \in \mathbb{T}} |f_{a,b}'(x)|$.

For each point $x$ there is an $n = n(x) = n_{j_0} + n_{j_1} + n_{j_2} + \cdots + n_{j_s}$ such that

$$N \leq n \leq N + n_{\text{max}}.$$  

We claim that

$$(f_{a,b}^N)'(x) \geq e^{\kappa_{10} N}.$$
This follows since

\[(f_{a,b}^N)^\prime(x) = (f_{a,b}^n)^\prime(x)/(f_{a,b}^{n-N})^\prime(f_{a,b}(x)) \geq e^{\kappa_9 N} d_1^{\max} \geq e^{\kappa_{10} N},\]

for a suitably \(\kappa_{10}\). We conclude that the statement of Proposition 8.1 holds. \(\square\)

We now have all ingredients for the proof of Theorem A.

Let \(\omega_0\) be an interval as defined in Proposition 7.1 satisfying (7.1) and let \(\tilde{E}_b\) be the set defined in this proposition. Let \(\tilde{E}_b = \tilde{E}_b^N \supset \tilde{E}_b\) be the set corresponding to the \(N\)th-order construction of Proposition 8.1. Here \(N\) is determined as the smallest integer satisfying \(e^{-\hat{N}} \leq d\) as in the proof of Proposition 8.1. By (8.1) it then follows that the conclusion of Theorem A holds.

9. Proof of Theorem B

In this section we prove our last result. The methods of its proof will be completely different than the ones used in the rest of the paper. We will use the term ‘countable’ in the sense of ‘at most countable’. For the definitions, see the Introduction.

Proof of Theorem B. Fix \(b < 1\). Each tongue is open, so the set \(T_b\) is open. Therefore, it is the union of countably many components, each of them an open interval. Since the points on the boundary of a tongue belong to \(TN\), and the sets \(T\) and \(TN\) are disjoint, each component is contained in one tongue.

We claim that the intersection of the closures of two distinct components \(A_1\) and \(A_2\) is empty. Suppose it is not and that \(a\) belongs to this intersection. Then \((a, b) \in TN\), so it has its type. This type must be the same as the type of each of the tongues containing \(A_1\) and \(A_2\), so those types are the same, that is, \(A_1\) and \(A_2\) are contained in the same tongue. If \(n\) is the period of the neutral periodic orbit of \(f_{a,b}\), the map \(f_{a,b}^n\) has an interval on which it looks like one of Cases 1, 2 or 4 of Lemma 4.1 of [19]. By Theorem 4.1 and Lemma 2.6 of [20], this cannot be Case 4 (a neutral periodic point repelling from both sides), and by Lemma 4.2 of [19] it cannot be Case 1 or 2 (a neutral periodic point repelling from one side). This proves our claim.

If a parameter \(a \in TN_b\) does not belong to a boundary of a component of \(T_b\), then by Lemma 4.2 of [19] the neutral periodic orbit of \(f_{a,b}\) is repelling from both sides (Case 4), so by Theorem 4.1 and Lemma 2.6 of [20] \(a\) is isolated in the set of elements of \(T_b \cup TN_b\) which have type of the same period. This proves that there are only countably many such values of \(a\).

By the claim, the complement of \(T_b\) is a closed set without isolated points. The set \(TN_b\) is countable. Therefore \(E_b\) (which is the complement of \(T_b\) minus \(TN_b\)) is dense in the complement of \(T_b\).

The second part of the statement follows from the first and the fact that each component of \(T_b\) is contained in one tongue. \(\square\)

Acknowledgements. The authors would like to thank the referee for his careful reading and several valuable suggestions and corrections. The authors would like to thank the Göran Gustafsson Foundation UU/KTH for financial support. The research of
Michał Misiurewicz was partially supported by grant no. 4266012 from the Simons Foundation, and the research of Michael Benedicks was partially supported by the Swedish Research Council, grant no. 2016-05482.
