**Abstract**

**Background:** Carbon tetrachloride (CCl₄) is a potent nephrotoxin, as it causes acute as well as chronic toxicity in kidneys. Therefore, this study was carried out to assess the pharmacological potential of different fractions of *Carissa opaca* fruits on CCl₄-induced oxidative trauma in the kidney.

**Methods:** The parameters studied in this respect were the kidney function tests viz. serum profile, urine profile, genotoxicity, characteristic morphological findings, and antioxidant enzymatic level of kidneys.

**Result:** The protective effects of various fractions of *C. opaca* fruits against CCl₄ administration were reviewed by rat renal function alterations. Chronic toxicity caused by 8-week treatment of CCl₄ to the rats significantly decreased the pH level, activities of antioxidant enzymes, and glutathione contents, whereas a significant increase was found in the case of specific gravity, red blood cells, white blood cells, level of urea, and lipid peroxidation in comparison to control group. Administration of various fractions of *C. opaca* fruit with CCl₄ showed protective ability against CCl₄ intoxication by restoring the urine profile, activities of antioxidant enzymes, and lipid peroxidation in rat. CCl₄ induction in rats also caused DNA fragmentation and glomerular atrophy by means of dilation, disappearance of Bowmen’s space, congestion in the capillary loops, dilation in renal tubules, and foamy look of epithelial cells of tubular region, which were restored by co-administration of various fractions of *C. opaca*.

**Conclusion:** Results revealed that the methanolic fractions of *C. opaca* are the most potent and helpful in kidney trauma.

**Keywords:** Carissa opaca fruits; oxidative trauma; genotoxicity; lipid peroxidation; DNA fragmentation
and decrease the activity of a diagnostic marker enzyme creatinine phosphokinase (an enzyme responsible for ATP regeneration) in cardiac tissue (15). The health-promoting effect of antioxidants on oxidative damage is mostly examined through the cellular antioxidants including the enzymatic behavior of catalase (CAT), peroxidase (POD), superoxide dismutase (SOD), glutathione peroxidase (GPx), glutathione-S-transferase (GST), and glutathione reductase (GR), in addition to TBARS (a product of lipid peroxidation) and reduced glutathione (GSH) level (16) among various tissues. Previous studies have shown that antioxidants, including naringenin, N-acetyl cysteine, vitamin E, silymarin, quercetin, and rhin decrease lipid peroxidation, and partially ameliorate tissue injuries (16). Over the years, many researchers have reported that plants containing phenolics and flavonoids exhibit a large array of biological activities such as hepatoprotection, cardio-protection, and reversal of fibrosis. These phytochemicals are widely found in fruits and vegetables as an important part of the human diet. Consequently, plants like dietary substances may be reliable guards against tissue damage, as well as a mechanism in curtailting the progression to lethal diseases like cancer (17). *Carissa opaca* Stapf ex Hanes is a 2–3 m tall evergreen shrub containing glabrous or puberulous branches with opposite and ovate glabrous leaves, hard and sharp spines arising between the petiole widely found in Pakistan and in some areas of India, Burma, and Sri Lanka (17). Traditionally, this plant is used for the treatment of asthma and pulmonary diseases (18), anticancer (19), diarrhea (20), hepatoprotection (21), and reproductive dysfunction (22). Therefore, the present study aimed to assess the nephro-protective potential of different fractions of *C. opaca* fruits on CCl₄-induced oxidative trauma in the kidney.

**Plant collection**

The ripened fruits of *C. opaca* were collected in March–April 2011 from the Quaid-i-Azam University Islamabad and Abbottabad of Northern Pakistan, respectively. The plants were recognized by their local names and then validated by Dr. Mir Ajab Khan, Department of Plant Sciences, Quaid-i-Azam University, Islamabad, and Dr. Saleem Ahmad, Curator, Pakistan Museum of Natural History, Islamabad. A voucher specimen with Accession No. 24561 (*C. opaca*) was deposited at the Herbarium of Pakistan, Museum of Natural History, Islamabad.

**Extract preparation**

The collected plant samples were cleaned to get rid of dust particles and then dried under shade for 1–2 weeks. Willy Mill of 60-mesh size was used to prepare powder of dried samples, and then each powdered plant sample was used for further solvent extraction. First of all, 5 kg of powdered sample was extracted twice with 10 L of 95% methanol at 25°C for 48 h. For filtration, Whatman No. 1 filter paper was used, and then the filtrate was concentrated on rotary evaporator (Panchun Scientific Co., Kaohsiung, Taiwan) under reduced pressure at 40°C. To resolve the compounds with escalating polarity, a part of the extract was suspended in distilled water and subjected to liquid–liquid partition by using solvents in the sequence of n-hexane, ethyl acetate, and methanol. After fractioning, the solvent of respective fractions was also evaporated by rotary evaporator. Fractions of n-hexane (HFC), ethyl acetate (EFC), and methanol (MFC) were obtained and were stored at 4°C for further in vivo investigation.

**Experimental plan**

A total of 42, 6-week-old, male Sprague–Dawley rats weighing 180±10 g were purchased from the National Institute of Health (NIH), Islamabad. Rats were given food and water *ad libitum* and kept at 20–22°C on a 12-h light–dark cycle. The study protocol was approved by ethical committee of Quaid-i-Azam University, Islamabad. The rats were acclimatized to laboratory condition for 7 days before commencement of experiments and then randomly divided into seven groups (six rats per group). Administration of CCl₄ (0.5 ml/kg b.w., 20% CCl₄/olive oil) was intraperitoneally (i.p.) administered twice a week for 8 weeks. At the same time, the rats were individually administered silymarin (50 mg/kg b.w.) in DMSO and various fractions including HFC, EFC, and MFC (200 mg/kg b.w.) orally twice a week for 8 weeks. At the end of 8 weeks, 24 h after the last treatment, urine was collected and stored at −70°C for further analysis, and then animals were given chloroform anesthesia and then dissected. All animals were sacrificed; blood was drawn prior to the excision of organ tissues from the ventral side through cardiac puncture. The serum was stored at −80°C after separation until it was assayed, as described below. Kidneys were removed and washed in ice-cold saline. Subsequently, half of the organs were treated with liquid nitrogen and stored at −80°C for further enzymatic and DNA damage analysis while the other portion was processed for histology (5).

**Biochemical investigations**

Evaluation of the pharmacological effects of different fractions of *C. opaca* against the toxicity induced with CCl₄ in rats has been done following assays as described by Khan et al. (5).

**Physical analysis of urine**

Urine samples were assayed for red blood cells (RBCs) count, white blood cells (WBCs) count, urobilinogen, pH, and specific gravity by using standard diagnostic kits (MediScreen Urine Strips, Organics, France).
Biochemical analysis of urine and serum
Estimation of total protein, albumin, urea, creatinine, and creatinine clearance was done by using standard diagnostic kits (MediScreen kit France).

Assessment of antioxidant enzymes
In total, 10% homogenate of tissue was prepared in 100 mM KH2PO4 buffer containing 1 mM ethylenediaminetetraacetic acid (EDTA; pH 7.4) and centrifuged at 12,000 × g for 30 min at 4 °C. The supernatant was collected and used for the following parameters as described below.

Catalase assay
CAT activities were determined by the method of Chance and Maehly (23) with some modifications. The reaction solution of CAT activities contained: 2.5 ml of 50 mM phosphate buffer (pH 5.0), 0.4 ml of 5.9 mM H2O2, and 0.1 ml enzyme extract. Changes in absorbance of the reaction solution at 240 nm were determined after 1 min. One unit of CAT activity was defined as an absorbance change of 0.01 as units/min.

Peroxidase assay
Activities of POD were determined by the method of Chance and Maehly (23) with some modifications. The POD reaction solution contained: 2.5 ml of 50 mM phosphate buffer (pH 5.0), 0.1 ml of 20 mM guaiacol, 0.1 ml enzyme extract of 10% (100 mg) tissue homogenate. The activities of POD were determined by the method of Chance and Maehly (23) with some modifications. The reaction solution contained: 2.5 ml of 50 mM phosphate buffer (pH 5.0), 0.4 ml of 5.9 mM H2O2, and 0.1 ml enzyme extract. Changes in absorbance of the reaction solution at 470 nm were determined after 1 min. One unit of POD activity was defined as an absorbance change of 0.01 units/min.

Superoxide dismutase assay
SOD activity was estimated by the method of Kakkar et al. (24). A mixture containing 0.1 ml of phenazine methosulfate (186 μM), 1.2 ml of sodium pyrophosphate buffer (0.052 mM; pH 7.0), and 0.3 ml of supernatant after centrifugation (1,500 × g for 10 min followed by 10,000 × g for 15 min) of kidney homogenate was added to this reaction mixture. Enzyme reaction was initiated by adding 0.2 ml of NADH (780 μM) and stopped after 1 min by adding 1 ml of glacial acetic acid. Amount of chromogen formed was measured by recording color intensity at 560 nm. Results are expressed in units/mg protein.

Glutathione-S-transferase assay
GST activity was assayed by the method of Habig et al. (25). The reaction mixture consisted of 1.475 mM phosphate buffer (0.1 mol, pH 6.5), 0.2 ml reduced glutathione (1 mM), 0.025 ml (CDNB) (1 mM), and 0.3 ml of homogenate in a total volume of 2.0 ml. The changes in the absorbance were recorded at 340 nm, and enzymes activity was calculated as nM CDNB conjugate formed/min/mg protein using a molar extinction coefficient of 9.6 × 105 M−1 cm−1.

Glutathione reductase assay
GR activity was determined by the method of Carlberg and Mannervik (26). The reaction mixture consisted of 1.65 ml phosphate buffer: (0.1 mol; pH 7.6), 0.1 ml (0.5 mM EDTA), 0.05 ml oxidized glutathione (1 mM), 0.1 ml nicotinamide adenine dinucleotide phosphate (NADPH), and 0.1 ml of homogenate in a total volume of 2 ml. Enzyme activity was quantitated at 25 °C by measuring the disappearance of NADPH at 340 nm and was calculated as nM NADPH oxidized/min/mg protein using molar extinction coefficient of 6.22 × 103 M−1 cm−1.

Glutathione peroxidase assay
GPx activity was assayed by the method of Mohandas et al. (27). The reaction mixture consisted of 1.49 ml phosphate buffer (0.1 M; pH 7.4), 0.1 ml EDTA (1 mM), 0.1 ml sodium azide (1 mM), 0.05 ml GR (1 IU/ml), 0.05 ml GSH (1 mM), 0.1 ml NADPH (0.2 mM), 0.01 ml H2O2 (0.25 mM), and 0.1 ml of homogenate in a total volume of 2 ml. The disappearance of NADPH at 340 nm was recorded at 25 °C. Enzyme activity was calculated as nM NADPH oxidized/min/mg protein using molar extinction coefficient of 6.22 × 103 M−1 cm−1.

Quinone reductase assay
The activity of quinone reductase (QR) was determined by the method of Benson et al. (28). The 3.0 ml reaction mixture consisted of 2.13 ml Tris-HCl buffer (25 mM; pH 7.4), 0.7 ml bovine serum albumin, 0.1 ml FAD, 0.02 ml NADPH (0.1 mM), and 0.1 ml of homogenate. The reduction of dichlorophenolindophenol (DCPIP) was recorded at 600 nm, and enzyme activity was calculated as nM of DCPIP reduced/min/mg protein using molar extinction coefficient of 2.1 × 104 M−1 cm−1.

Reduced glutathione assay
Reduced GSH was estimated by the method of Jollow et al. (29). A volume of 1.0 ml of homogenate was precipitated with 1.0 ml of (4%) sulfosalicylic acid. The samples were kept at 4 °C for 1 h and then centrifuged at 1,200 × g for 20 min at 4 °C. The total volume of 3.0 ml assay mixture contained 0.1 ml filtered aliquot, 2.7 ml phosphate buffer (0.1 M; pH 7.4), and 0.2 ml DTNB (100 mM). The yellow color developed was read immediately at 412 nm on a SmartSpecTM plus Spectrophotometer. It was expressed as μM GSH/g tissue.

Estimation of lipid peroxidation assay
The assay for lipid peroxidation was carried out following the modified method of Iqbal et al. (30). The reaction mixture in a total volume of 1.0 ml contained 0.58 ml phosphate buffer (0.1 M; pH 7.4), 0.2 ml homogenate sample, 0.2 ml ascorbic acid (100 mM), and 0.02 ml ferric chloride (100 mM). The reaction mixture was incubated at 37 °C in a shaking water bath for 1 h. The reaction was stopped by the addition of 1.0 ml of 10% trichloroacetic acid followed by the addition of 1.0 ml of 10% trichloroacetic acid.
acid (TCA). Following the addition of 1.0 ml of 0.67% thiobarbituric acid, all the tubes were placed in a boiling water bath for 20 min and then shifted to a crushed ice-bath before centrifuging at 2,500 \( \times g \) for 10 min. The amount of TBARS formed in each of the samples was assessed by measuring the optical density of the supernatant at 535 nm using spectrophotometer against a reagent blank. The results were expressed as nM TBARS/min/mg tissue at 37°C using molar extinction coefficient of 1.56 \( \times 10^5 \) M\(^{-1}\) cm\(^{-1}\).

Hydrogen peroxide assay

Hydrogen peroxide (H\(_2\)O\(_2\)) was assayed by H\(_2\)O\(_2\)-mediated horseradish peroxidase-dependent oxidation of phenol red by the method of Pick and Keisari (31). A volume of 2.0 ml of homogenate sample was suspended in 1.0 ml of solution containing phenol red (0.28 nM), horse radish peroxidase (8.5 units), dextrose (5.5 nM), and phosphate buffer (0.05 M; pH 7.0) and incubated at 37°C for 60 min. The reaction was stopped by the addition of 0.01 ml of NaOH (10 N) and then centrifuged at 800 \( \times g \) for 5 min. The absorbance of the supernatant was recorded at 610 nm against a reagent blank. The quantity of H\(_2\)O\(_2\) produced was expressed as nM H\(_2\)O\(_2\)/min/mg tissue based on the standard curve of H\(_2\)O\(_2\) oxidized phenol red.

Molecular studies

DNA has been isolated and its fragmentation percent was quantified in molecular studies of in vivo toxicity.

DNA fragmentation assay with diphenylamine reaction

DNA fragmentation from tissue extract was determined using the procedure of Wu et al. (32). A quantity of 100 mg tissue was homogenized in Tris triton EDTA (TTE) solution. A volume of 0.1 ml of homogenate was labeled B, centrifuged at 200 \( \times g \) at 4°C for 10 min, and the supernatant was collected and labeled S. S tubes were centrifuged at 20,000 \( \times g \) for 10 min at 4°C to separate intact chromatin and was labeled T. A volume of 1.0 ml of 25% TCA was added to all tubes T, B, S and incubated overnight at 4°C. After incubation, precipitated DNA was recovered by pelleting for 10 min at 18,000 \( \times g \) at 4°C. A volume of 160 \( \mu l \) of 5% TCA was added to each pellet and heated for 15 min at 90°C, then 320 \( \mu l \) of freshly prepared DPA solution was added, vortexed, and incubated for 4 h at 37°C. Optical density was read at 600 nm with a spectrophotometer (Smart spec™ Plus, catalogue # 170-2525).

Results

Effects of C. opaca fruit against CCl\(_4\)-induced nephrotoxicity in rat

The present achievements were used to assess the medicinal potential of various fractions of C. opaca fruit against CCl\(_4\)-induced oxidative damages in rat kidney. The biochemical alterations in different groups of rats were collaborated by the renal histological architectures of respective groups. The results obtained in this context are given below.

Effects of C. opaca fruits on urine profile of rat

The protective effects of various fractions of C. opaca fruits against CCl\(_4\) administration were reviewed by rat renal functions alterations. Table 1 presents urine profile including urinary pH, specific gravity, RBCs, WBCs, and level of urea. Chronic toxicity caused by 8-week treatment of CCl\(_4\) to the rats significantly decreased the pH level, whereas a significant increase was found in the cases of specific gravity, RBCs, WBCs, and level of urea in comparison to control group. Table 2 demonstrates a marked increase in urinary creatinine and urobilinogen whereas creatinine clearance, urinary albumin, and level of urinary proteins...
were significantly decreased by CCl₄ administration (p < 0.05) in contrast to control group. Administration of various fractions of C. opaca fruit with CCl₄ showed protective ability against CCl₄ intoxication by restoring the urine levels of rat. Results of urine analysis for the groups treated with fractions alone did not show any toxic effects as their values were near to control. Data show that almost all fractions had significant pharmacological effects for urine versus diseased group.

Effects of C. opaca fruits on serum profile of rats

Effects of different fractions of C. opaca fruits on serum profile of kidneys are summarized in Tables 3 and 4. Table 3 presents serum protein, albumin, globulin, total bilirubin, and direct bilirubin of serum. There was a significant reduction in protein, albumin, and globulin level of serum in CCl₄-toxicated group, while total bilirubin and direct bilirubin of serum were improved in CCl₄-toxicated group. Table 4 summarizes the blood urea nitrogen (BUN), urobilinogen, creatinine, creatinine clearance, and nitrite level of serum. Administration of CCl₄ significantly enhanced the BUN, urobilinogen, creatinine, and nitrite level of serum, whereas reduced the creatinine clearance of serum. Silymarin was used as a reference drug to reduce nephrotoxicity.

Effects of C. opaca fruits on antioxidant levels

Nature has developed metabolic systems in various organisms to reduce the oxidative damage and avoid different lethal damage to cells and tissues. During this natural process, various oxidative metabolites are formed as a by-product in the cells. Antioxidant enzymes reduce these metabolites in a scavenging process. In this study, activities and scavenging effects of various antioxidative enzymes were studied. Effects of various fractions of C. opaca fruits and CCl₄ on tissue soluble protein and antioxidant defense enzyme systems such as CAT, POD, SOD, TBARS, and H₂O₂ are shown in Table 5. CCl₄ administration to rats significantly decreased tissue protein and disturbs the antioxidative status by lessening the renal catalase, peroxidase, and superoxide levels, and increased the lipid peroxidation and hydrogen peroxide levels in comparison to control group. Co-administration of various fractions of C. opaca fruits with CCl₄ enhanced the activity of suppressed enzymes and the soluble protein, whereas reduced the activity of elevated enzymes. However, non-significant change was recorded with the treatment of fractions alone against the control group.

Table 6 shows the levels of phase II metabolizing antioxidant enzymes including GST, G Px, GR, GSH, QR, and DNA fragmentation in renal tissues of different

Citation: Food & Nutrition Research 2015, 59: 28438 - http://dx.doi.org/10.3402/fnr.v59i28438
Treatment of rats with CCl4 significantly increased the enzymatic group but decreased the level of DNA injuries. Post-administration of various fractions of C. opaca fruits along with CCl4 treatment markedly reversed the level of GST, GPx, GR, GSH, and QR while diminished the levels of GST, GPx, GR, GSH, and QR, and DNA fragmentation. Silymarin administered to the intoxicated group completely suppressed the effect of CCl4 and increased the level of glutathione enzymatic group but decreased the level of DNA injuries. Treatment of rats with CCl4 significantly increased the renal tissue DNA damages than those of control group. The groups treated with CCl4 significantly abridged the DNA fragmentation versus the diseased group treated with CCl4 alone. The results of oxidative enzymatic studies are also in harmony with the consequences of urinary and serological studies.

**Effects of C. opaca fruits on DNA damages (ladder assay)**

DNA was extracted from renal tissues of the treated rats by a stepwise method and then was loaded on 1.5% agarose gel. Figure 1 details the banding pattern of DNA. In case of CCl4-intoxicated rats, a peculiar fragmentation of DNA can be observed, which was absent from the renal tissues of control rats. DNA extracted from the group treated with various fractions of C. opaca fruits along with CCl4 showed a markedly repaired DNA. The groups treated with only various fractions did not show any kind of DNA damage.

**Effects of C. opaca fruits on kidney histoarchitecture**

Histological architecture of kidneys of different groups is summarized in Fig. 2. The histopathologically observed changes showed that the intraperitoneal injection of CCl4 for 8 weeks resulted in severe impairment to cortical region of kidneys. The damage induced was in different forms of degenerations showing glomerular atrophy by means of dilation and disappearance of Bowmen’s space, congestion in the capillary loops, dilation in renal tubules, and foamy look of epithelial cells of tubular region (Fig. 2c). In addition, subchronic administration of CCl4 exhibited interstitial inflammatory cells infiltration in both corticu- and medullary regions. The evaluation of kidney section of control and DMSO group had normal histological architecture as shown in Fig. 2a and b. Renal sections of rats treated with various fractions of C. opaca fruits (HFC, EFC, and MFC) reversed the CCl4 intoxication and showed mild injury in contrast to control group (Fig. 2d–f). The histological appearance of glomeruli and Bowman’s capsule was almost normal, and only some of the glomeruli were degenerated. Mild necrosis in the

Discussion

As we previously investigated, the methanol fraction of *C. opaca* is rich in active compounds such as orientin, isoquercitin, myricetin, and apigenin (20). Hence, it is proposed that these fractions might have protection against degenerative diseases caused by oxidative stress. CCl$_4$ intoxication generates free radicals that trigger a cascade of events resulting in nephrotoxicity. Activation of cytochrome P$_{450}$ oxygenase system yields highly reactive trichloromethyl peroxy radical that initiate lipid peroxidation (33). The lipid peroxidation may cause peroxidative tissue damage (34). Relevant to the latter findings, plant extract and its fractions comprehensively ameliorate the injuries induced through CCl$_4$ intoxication and affect the activity of biochemical enzymes, DNA strand breakage, and increase the activity of telomerase cancer marker enzyme of kidney tissue (35). The protective effects might seem to be related to their molecular structure, more precisely to the presence and number of hydroxyl groups, and to double bond conjugation and resonance effects substituents in the phenyl ring and on the position of its nitrogen atom relative to the N–H bond as was previously reported (36, 37).

Previous studies reported that the urine analysis provides information about the functional status of kidneys. It can be said that malfunctioning kidneys result in distressed urine profiles. Urobilinogen, RBCs, and acidic pH are not the components of urine in normal conditions; however, the presence of significantly higher amount of urobilinogen, RBCs, and acidic pH was observed in urine that may be the result of oxidative damage in kidney of CCl$_4$-intoxicated rats. Besides this, the elevated levels of WBCs, urinary creatinine, and urea, and decline in creatinine clearance, albumin, and proteins of urine were an indication of severe kidney damage. Similarly, the specific gravity of urine correlates with osmolality (36), and increased specific gravity is one of the symptoms of kidney damages such as dehydration, renal artery stenosis, necrosis, decreased blood flow to kidneys, and proteinuria (37). The present study exposed that various fractions of tested plant samples showed different levels of ameliorating effects by normalization of urinary profile.

Sedlak and Snyder (38) reported that the bilirubin is an important physiological cytoprotectant due to its antioxidant ability. At present, administration of CCl$_4$ indicated the risk of impaired-renal function by elevation of serum glomeruli and tubules was observed. As a measure of protective effects, silymarin was also induced to a group of rats (Fig. 2d). Silymarin treatment erased the CCl$_4$ pathogenesis, relative to control group. These findings are in agreement with the rest of the parameters studied.

creatinine, BUN, nitrite level, urobilinogen, total bilirubin, and direct bilirubin (39). Decrease in total globulin and albumin of serum pointed toward leakage due to injuries in the kidney. Decrease in serum creatinine, BUN, nitrite level, urobilinogen, total and direct bilirubin concentrations of groups that were treated with different plant fractions confirms a contributory mechanism of reduced oxidative stress. Previous studies have also revealed the similar conclusions against CCl4-induced oxidative stress in kidneys while dealing with different plant extracts/fractions or bioflavonoids (40). But our results discord as well as confirm the findings of Oguturk et al. (41) who reported non-significant change but increase in serum creatinine level after 1 month of CCl4 intoxication. Confiction may be attributed to lesser period of dosage administration. Urinary and serum profile studies proved their comcomitance with renal functionality. CCl4 intoxication alters the gene expression level by depleting renal SOD and catalase (42) while our tested fractions of plant samples ameliorated the renal toxicity by alleviated level of catalase, peroxidase, and SOD. GSH acts as a non-enzymatic protein thiol contributing in defense system against oxidative damages of both intracellular and extracellular environment. It participates in various enzymatic processes to reduce the concentration of peroxides by its redox and detoxification reaction (43). Under oxidative stress conditions reduced GSH is oxidized, thus it specifies that depletion in GSH content and an increase in TBARS and H2O2 of kidney tissue are an indication of strong renal injuries. Administration of different fractions of tested plant samples showed a clear-cut elevation in the amount of GSH that was concomitant with a reduction in TBARS and H2O2 contents, hence verifying the protection against CCl4 challenges. These findings were consistent with the literature. Our results are consistent with Soni et al. (44) who reported that CCl4-induced oxidation caused an increase in TBARS content and lessened antioxidant enzymatic and non-enzymatic indicators of serum and renal tissue. Present observations are in agreement with previous demonstrations that hesperidin is a bioflavonoid, which reduces the production of CCl4-induced free radical by improving GSH levels of kidneys and decreases the concentration of 8-hydroxydeoxyguanosine (8-OH-dG), a marker of DNA fragmentation (45). Consequently, improvement in antioxidant enzyme levels such as CAT, POD, SOD, and phase II metabolizing enzymes (GST, GR, GPx, and QR) in contrast to CCl4-injected rats revealed the antioxidative trend of different fractions of tested plant samples. Increased DNA damage ultimately turns into cell proliferation and apoptosis (46–48). CCl4 administration is the major cause of oxidative stress and reactive oxygen species in the cell. It enhances the formation of the lipid peroxide radicals, which accelerate the breakdown of polyunsaturated fatty acids (PUFAs). Persistent oxidative stress induces DNA damage by modifying base products and results in strand breaks, which may lead to further mutation and chromosomal aberrations (49). Endonucleases degrade the cellular DNA to induce tubular epithelial cell death of kidney tissue. Overproduction of free radicals triggers the activity of Deoxyribonuclease I (DNase I) (50). DNase I, a highly reactive renal endonuclease I, attributes to about 80% of the total endonuclease action in renal tissues (51). Under these circumstances, it is possible that prevention of CCl4-induced renal DNA damage might be due to modulation of DNase I activity. Our findings are consistent with Nagwani and Tripathi (52), who reported similar results in amelioration of cisplatin-induced nephrotoxicity by PTY, a herbal preparation. The histopathological findings in kidney correlate with biochemical estimations of studied experimental groups. CCl4 challenges produced an ischemic environment leading to glomerular and tubular lesions with vasocongestion in kidney. Similar histopathological architecture was observed by Dogukan et al. (53) in renal tissue of rats in response to chronic administration of CCl4 for 7 weeks. It is also thought that histopathological alterations may be associated with the absorption power of renal tubules that introduce functional overloading of nephrons with subsequent renal dysfunction (12). Regarding other kidney function tests, it can be revealed that the mechanism of CCl4 to intend nephrotoxicity and hepatotoxicity is probably the same. It can be concluded that the natural antioxidants such as flavonoids or plant fractions are direct means to protect the cell against potent toxins and chemicals; hence, the present study verifies the enhanced repairing effects of different fractions of tested plant materials. Our findings are in harmony with other studies who reported that different fractions of plants have

Lanes from left: (M) low molecular weight marker, (1) control, (2) DMSO+Olive oil group, (3) CCl4 group, (4) silymarin+CCl4 group, (5) MFC+CCl4 group, (6) EFC+CCl4 group, (7) HFC+CCl4 group.](image-url)
pharmacological effects by erasing the CCl₄ insults and reverting toward normalcy (41).

**Conclusion**
The present study provides additional scientific evidences verifying that methanol extracts of *C. opaca* are strong antioxidants capable of protecting the kidney from CCl₄-induced trauma. The protective effect observed in this study provides some mechanistic evidence for why indigenous people of Southeast Asia found it useful for treating kidney ailments as well as being used as a food additive.

**Authors’ contributions**
SS made significant contribution to acquisition and interpretation of data, conception, and drafting of the manuscript. MRK, HMA, and RAK (ORCID ID: 0000-0003-0453-2090) have made substantial contribution to conception and design, interpretation of data, and drafting for intellectual content.

**Conflict of interest and funding**
The authors have not received any funding or benefits from industry or elsewhere to conduct this study.
