NULL CONTROLLABILITY OF THE INCOMPRESSIBLE
STOKES EQUATIONS IN A 2-D CHANNEL USING NORMAL
BOUNDARY CONTROL

(Communicated by Viorel Barbu)

Abstract. In this paper, we consider the Stokes equations in a two-dimen-
sional channel with periodic conditions in the direction of the channel. We
establish null controllability of this system using a boundary control which acts
on the normal component of the velocity only. We show null controllability of
the system, subject to a constraint of zero average, by proving an observability
inequality with the help of a Müntz-Szász Theorem.

1. Introduction. We consider a viscous incompressible fluid flow in a two-dimen-
sional periodic channel, defined by \((x, y) \in (-\infty, \infty) \times [0, 1]\), with the walls located
at \(y = 0\) and \(y = 1\). So the boundary of the channel is split into two parts,
namely the upper and the lower part. The Navier-Stokes equations for a viscous incompressible fluid for \((x, y) \in (-\infty, \infty) \times (0, 1) \subset \mathbb{R}^2 \) and \(t \in (0, T)\) are

\[
\frac{\partial U}{\partial t}(x, y, t) + (U(x, y, t) \cdot \nabla)U(t, x, y) - \nu \Delta U(x, y, t) = \nabla p(x, y, t),
\]

\[
\forall (x, y, t) \in (-\infty, \infty) \times (0, 1) \times (0, T),
\]

\[
\text{div} \, U(x, y, t) = 0, \quad \forall (x, y, t) \in (-\infty, \infty) \times (0, 1) \times (0, T),
\]

Thus \( U \) null controllable by the control acting in the normal direction of the boundary. Note consequently,

\[
\begin{align*}
\int_0^L \psi(x, t) \, dx & = 0, \quad \forall t \in (0, T), \\
\text{div } U & = 0 \quad \text{in } (-\infty, \infty) \times (0, 1) \times (0, T), \\
U(x, 0, t) & = (0, 0), \quad \forall (x, t) \in (-\infty, \infty) \times (0, T), \\
U(x, 1, t) & = (0, \psi(x, t)), \quad \forall (x, t) \in (-\infty, \infty) \times (0, T), \\
U(x, y, 0) & = (u_0(x, y), v_0(x, y)), \quad \forall (x, y) \in (-\infty, \infty) \times (0, 1),
\end{align*}
\]

where \( U(x, y, t) = (u(x, y, t), v(x, y, t)) \) denotes the velocity of the fluid in \( \mathbb{R}^2 \), \( p(x, y, t) \) denotes the pressure and \( \psi \) is the boundary control. The viscosity coefficient \( \nu \) is assumed to be a positive constant and \( L \) is any positive number. A simple stationary solution (with \( \psi = 0 \)) of system (1.1) is given by \( (U, p) = (0, 0, 0) \), corresponding to a fluid at rest.

We assume that both the velocity field \( U = (u, v) \) and the pressure \( p \) are \( L \)-periodic in the first spatial coordinate \( x \).

Here we consider the following linearized system of (1.1).

\[
\begin{align*}
\frac{\partial U}{\partial t} - \nu \Delta U & = \nabla p \quad \text{in } (-\infty, \infty) \times (0, 1) \times (0, T), \\
\text{div } U & = 0 \quad \text{in } (-\infty, \infty) \times (0, 1) \times (0, T), \\
U(x, 0, t) & = (0, 0) \quad \forall (x, t) \in (-\infty, \infty) \times (0, T), \\
U(x, 1, t) & = (0, \psi(x, t)), \quad \forall (x, t) \in (-\infty, \infty) \times (0, T), \\
U(x + L, y, t) & = U(x, y, t), \quad \forall (x, y, t) \in (-\infty, \infty) \times (0, 1) \times (0, T), \\
p(x + L, y, t) & = p(x, y, t), \quad \forall (x, y, t) \in (-\infty, \infty) \times (0, 1) \times (0, T), \\
U(x, y, 0) & = U_0(x, y), \quad \forall (x, y) \in (-\infty, \infty) \times (0, 1) \times (0, T).
\end{align*}
\]

Definition 1.1. The system (1.2) is null controllable in a Hilbert space \( Z \) at time \( T > 0 \), if for any initial condition \( U_0 \in Z \), there exists a control \( \psi \) such that the solution \( U \) of (1.2) with control \( \psi \) hits 0 at time \( T \), i.e. \( U(T) = 0 \).

Our goal in this paper is to study the null controllability of the linearized system (1.2) by using a control \( \psi \) acting only in the normal direction on the upper part of the boundary. Due to the incompressibility condition \( \text{div } U = 0 \), we necessarily have

\[
\int_0^L \psi(x, t) \, dx = 0, \quad \forall t \in (0, T). \tag{1.3}
\]

The main obstacle to null controllability using only one control acting in the normal direction of the boundary is as follows. In (1.2), we denote \( U(x, y, 0) = U_0(x, y) = (u_0, v_0) \) and \( U = (u, v) \). Taking a dot product between (1.2) and \( (\sin(n\pi y), 0) \) and then using an integration by parts on \( (0, L) \times (0, 1) \) and the condition (1.3), we get

\[
\frac{d}{dt} \int_0^L \int_0^1 u(x, y, t) \sin(n\pi y) \, dy \, dx = -\nu n^2 \pi^2 \int_0^L \int_0^1 u(x, y, t) \sin(n\pi y) \, dy \, dx.
\]

Consequently,

\[
\int_0^L \int_0^1 u(x, y, T) \sin(n\pi y) \, dy \, dx = e^{-\nu n^2 \pi^2 T} \int_0^L \int_0^1 u_0(x, y) \sin(n\pi y) \, dy \, dx.
\]

Thus \( U(x, y, T) = (0, 0) \) implies that the initial condition \( U_0(x, y) \) has to satisfy

\[
\int_0^L \int_0^1 u_0(x, y) \sin(n\pi y) \, dy \, dx = 0, \quad \forall n \in \mathbb{N}. \tag{1.4}
\]

So there are infinitely many directions, namely \( (\sin(l\pi y), 0), l \in \mathbb{N}, \) which are not null controllable by the control acting in the normal direction of the boundary. Note
that the subspace spanned by these directions is infinite-dimensional. The question then arises whether the system is null controllable in the orthogonal complement of this subspace, and this paper will answer this question affirmatively. If we do not restrict the initial condition, we cannot control the flow to zero, but we can control to a purely horizontal flow. This might be of interest, for instance, if the objective of the control is to preserve stratification.

In view of this discussion and (1.3), we study the null controllability of the linearized system by using the control acting in the normal direction of the boundary with appropriate constraints on the control and initial condition, i.e.

\[
\frac{\partial U}{\partial t} - \nu \Delta U = \nabla p \quad \text{in} \quad (-\infty, \infty) \times (0,1) \times (0,T),
\]

\[\text{div } U = 0 \quad \text{in} \quad (-\infty, \infty) \times (0,1) \times (0,T),\]

\[U(x,0,t) = (0,0), \quad \forall (x,t) \in (-\infty, \infty) \times (0,T),\]

\[U(x,1,t) = (0,\psi(x,t)), \quad \forall (x,t) \in (-\infty, \infty) \times (0,T),\]

\[\int_0^L \psi(x,t) \, dx = 0, \quad \forall t \in (0,T), \quad (1.5)\]

\[U(x+L,y,t) = U(x,y,t), \quad \forall (x,y,t) \in (-\infty, \infty) \times (0,1) \times (0,T),\]

\[p(x+L,y,t) = p(x,y,t), \quad \forall (x,y,t) \in (-\infty, \infty) \times (0,1) \times (0,T),\]

\[U(x,y,0) = U_0(x,y) = (u_0(x,y),v_0(x,y)), \quad \forall (x,y) \in (-\infty, \infty) \times (0,1),\]

\[\int_0^L u_0(x,y) \, dx = 0, \quad \forall y \in (0,1).\]

Using spectral methods we prove null controllability for \(U_0\) belonging to \(V_0^{\infty,n}(\Omega)\) with \(\int_0^L u_0(x,y) \, dx = 0\), for all \(y \in (0,1)\), where \(V_0^{\infty,n}(\Omega)\) denotes space of \(L\)-periodic divergence free \(L^2\) vector functions which have normal trace zero. (For details of the function spaces, see Section 2.1). This is the main result (see Theorem 3.1 in Section 3) of this paper.

As far as we know there are no prior null controllability results using one normal boundary control for the Stokes system (1.2).

The proof of the null controllability result relies on an observability inequality (see Section 3) for the solutions of the adjoint system and the spectral analysis of the linearized operator. The spectrum of the Stokes operator lies on the left side of the complex plane. It consists of a family of real eigenvalues, which diverges to \(-\infty\). Moreover, explicit expressions of eigenvalues and eigenfunctions in terms of a Fourier basis are obtained. This helps to split the observability inequality into observability inequalities corresponding to each Fourier mode of the adjoint system. The observability inequality for each mode will be established using a parabolic type of Ingham inequality. The proof that the observability inequality (Lemma 3.3) for the \(k\)th Fourier mode holds with a positive constant \(C_T\), independent of \(k\), is the key result in this work.

The stabilization of the incompressible Navier-Stokes system in a 2-D channel (with periodic conditions along the \(x\) axis) linearized around a steady-state parabolic laminar flow profile \((L(y),0)\) has been studied in Munteanu [12] and Barbu [4]. In particular, Munteanu in [12] proved that the linearized system of (1.1) around \((L(y) = C(y^3 - y),0)\) is exponentially stabilizable with some decay rate \(\omega, 0 < \omega \leq \nu \pi^2\) by a normal boundary, finite-dimensional feedback controller acting on the
upper wall $\Gamma_1(y = 1)$ only. A similar stability result for this linearized system when the normal velocity is controlled on the both walls $\Gamma_0(y = 0)$ and $\Gamma_1(y = 1)$ of the channel is proved by Barbu in [4]. In [3], Barbu established that the exponential stability of the linearized system around $(L(y), 0)$ can be achieved using a finite number of Fourier modes and a boundary feedback stochastic controller which acts on the normal component of velocity only. In the present paper (see Section 2.2), we also notice that the incompressible Navier-Stokes system (1.1) linearized around the origin $(0, 0)$ is stabilizable using only a normal boundary control, with any decay rate $\omega$ such that $0 < \omega \leq \nu\pi^2$. Thus we know that the exponential decay rate can be at most $\nu\pi^2$ for the linearized system. (See also equation (96) in Section 9 in [12] or Section 2 in [6]). A similar situation occurs also in Triggiani [16] for a linearized system where homogeneous boundary conditions on the tangential component $u$ of the velocity are of Neumann type.

The boundary stabilization of Navier-Stokes equations, with tangential controllers or normal controllers was studied in two dimensions, for example by Barbu [5, 4], Munteanu [13], Coron [17], Krstic [18],[1], [2], Raymond [15]. In most of these papers, either there are sufficiently many boundary controls so there are no missing directions, or stabilizability is proved but with no specific decay rate (except in [15]). In contrast, in this work we are using only one boundary control (acting on the normal component of velocity) on the upper part of the boundary and we are looking for null controllability instead of stabilizability.

In [6], Chowdhury and Ervedoza proved a local stabilization result for the viscous incompressible Navier-Stokes equations (1.1) at any exponential decay rate by a normal boundary control acting at the upper boundary. The linearized system around zero is exponentially stable with decay rate $\nu\pi^2$ but not stabilizable at a higher decay rate. To overcome this difficulty, the idea is to use the nonlinear term to stabilize the system in the directions which are not stabilizable for the linearized equations. The argument is based on the power series expansion method introduced by J.-M. Coron and E. Crépeau in [8] and described in [7, Chapter 8]. Coron and Guerrero in [9] consider the two-dimensional Navier-Stokes system in a torus. They establish the local null controllability with internal controls having one vanishing component. Note that in their case also the linearized control system around the origin is not null controllable. In fact for the linearized system infinitely many missing directions are there corresponding to

$$\lambda_1 \sin \frac{2n\pi x}{L} + \lambda_2 \cos \frac{2n\pi x}{L}, \quad n \in \mathbb{Z}, \quad \lambda_i \in \mathbb{R}, \quad i = 1, 2, \quad L > 0,$$

like our case here for $\sin(n\pi x)$. But in [9] the nonlinear term helps to get this null controllability using the return method. Coron and Lissy proved in [10] local null controllability for the three-dimensional Navier-Stokes equations on a smooth bounded domain of $\mathbb{R}^3$ using localized interior control with two vanishing components. In this case also, the linearized system is not necessarily null controllable even if the control is distributed on the entire domain. They show local null controllability using the return method together with a new algebraic method inspired by the works of M. Gromov. For our system also the study of null controllability for the nonlinear system (1.1) is an open question. Moreover null controllability of the linearized and nonlinear system when control is localized is an interesting issue. These are interesting challenges for future research.

This paper is organized as follows. In Section 2, we introduce function spaces required for our analysis. Then we study the behavior of the spectrum of the linearized
operator and well-posedness of the linearized system (1.2) and the corresponding adjoint system. In Section 3, we split the observability inequality into observability inequalities corresponding to each Fourier mode of the adjoint system. Thereafter we give the completion of the proof of the observability inequality using a Müntz-Szász Theorem for each mode and showing uniformity of the constant arising in the observability inequality. In this fashion, null controllability (Theorem 3.1) is proved.

2. Spectral analysis of the Stokes system. In this section we study the Stokes system using its modal description. In particular, we identify the modes which are null controllable for the linearized system.

2.1. Functional framework. Let

\[ \Omega = \{ (x, y) \in \mathbb{R}^2 : 0 < y < 1 \} \]

with boundary \( \Gamma = \Gamma_0 \cup \Gamma_1 \), where

\[ \Gamma_i = \{ (x, y) \in \mathbb{R}^2 : y = i \}, i = 0, 1 \]

and

\[ \Omega_L = (0, L) \times (0, 1), \quad \text{for } L > 0. \]

Define \( L^2_\alpha(\Omega) \) as

\[ L^2_\alpha(\Omega) = \{ f \in L^2_{loc}(\Omega) : f|_{\Omega_L} \in L^2(\Omega_L), f(x + L, y) = f(x, y) \text{ for a.e. } (x, y) \in \Omega \}. \]

We also define the space

\[ H^1_\alpha(\Omega) = \{ f \in L^2_\alpha(\Omega) : f|_{\Omega_L} \in H^1(\Omega_L), f(x, 0) = f(x, 1) = 0, \]

\[ f(0, y) = f(L, y) \text{ in the trace sense} \}. \]

Let us denote the vector valued functional spaces:

\[ L^2_\alpha(\Omega) = L^2_\alpha(\Omega) \times L^2_\alpha(\Omega), \quad H^1_\alpha(\Omega) = H^1_\alpha(\Omega) \times H^1_\alpha(\Omega), \]

and \( H^{-1}_\alpha(\Omega) \) is the dual space of \( H^1_\alpha(\Omega) \).

We now introduce the following spaces of divergence free vector fields:

\[ V^0_{\tau,n}(\Omega) = \{ U = (u, v) \in L^2_\alpha(\Omega) : \text{div } U = 0, \quad U.n = 0 \text{ on } \Gamma \} \],

(here the subscript \( n \) indicates the vanishing of the normal component) and

\[ V^1_\alpha(\Omega) = \{ U = (u, v) \in H^1_\alpha(\Omega) : \text{div } U = 0 \} \].

We also denote the dual space of \( V^1_\alpha(\Omega) \) by \( V^{-1}_\alpha(\Omega) \).

We also define the space of \( L^2 \) functions in \( (0, L) \) having mean-value zero by

\[ L^2(0, L) = \{ g \in L^2(0, L) : \int_0^L g(x) \, dx = 0 \}. \]

Let us denote by \( P \) the Helmholtz orthogonal projection operator from \( L^2_\alpha(\Omega) \times L^2_\alpha(\Omega) \) on to \( V^0_{\tau,n}(\Omega) \), defined as

\[ P(f) = f - \nabla q, \]

where \( q \) is the weak solution of

\[ \Delta q = \text{div } f, \quad \frac{\partial q}{\partial n} = f.n \text{ on } \Gamma. \]
Further, taking $\psi = 0$ in (1.5), the linear operator associated to (1.5) is the Stokes operator $A = \nu P \Delta$, with domain $\mathcal{D}(A) = H^2(\Omega) \cap V_{\sharp,n}^0(\Omega)$ in $V_{\sharp,n}^0(\Omega)$.

The next lemma recalls well known properties of the Stokes operator.

**Lemma 2.1.** The operator $(A, \mathcal{D}(A))$ is the infinitesimal generator of a strongly continuous analytic semigroup $(e^{tA})_{t \geq 0}$ on $V_{\sharp,n}^0(\Omega)$. The operator $(A, \mathcal{D}(A))$ is self-adjoint in $V_{\sharp,n}^0(\Omega)$, i.e. $\mathcal{D}(A) = \mathcal{D}(A^*)$ and $A = A^*$.

### 2.2. Linearized system and its modal description

Here we study the linearized system with a normal boundary control $\psi$ and some details of the spectrum of the corresponding linearized operator.

The adjoint problem corresponding to (1.5) is

$$-rac{\partial \Phi}{\partial t} = \nu \Delta \Phi + \nabla q \quad \text{in} \quad (-\infty, \infty) \times (0,1) \times (0,T),$$

$$\text{div} \, \Phi = 0 \quad \text{in} \quad (-\infty, \infty) \times (0,1) \times (0,T),$$

$$\Phi(x,0,t) = (0,0) = \Phi(x,1,t), \quad \forall (x,t) \in (-\infty, \infty) \times (0,1),$$

$$\Phi(x + L,y,t) = \Phi(x,y,t), \quad \forall (x,y,t) \in (-\infty, \infty) \times (0,1) \times (0,T),$$

$$q(x + L,y,t) = q(x,y,t) \quad \forall (x,y,t) \in (-\infty, \infty) \times (0,1) \times (0,T),$$

$$\Phi(x,y,T) = \Phi_T(x,y), \quad \forall (x,y) \in (-\infty, \infty) \times (0,1),$$

$$\int_0^L \Phi_T(x,y) \, dx = 0, \quad \forall y \in (0,1).$$

Let us consider the eigenvalue problem $\lambda \Phi = A \Phi = \nu P \Delta \Phi$ (to limit the number of different symbols, we use the same letters for the eigenfunctions as for the solution of the adjoint), i.e.

$$\lambda \Phi - \nu \Delta \Phi = \nabla q, \quad \text{div} \, \Phi = 0,$$

$$\Phi(x,0) = (0,0), \quad \Phi(x,1) = (0,0), \quad (2.2)$$

$$\Phi(x + L,y) = \Phi(x,y), \quad q(x + L,y) = q(x,y).$$

We expand $(\Phi,q) = (\phi,\xi,q)$ into Fourier series:

$$\phi(x,y) = \sum_{k \in \mathbb{Z}} \phi_k(y) e^{ikx},$$

$$\xi(x,y) = \sum_{k \in \mathbb{Z}} \xi_k(y) e^{ikx},$$

$$q(x,y) = \sum_{k \in \mathbb{Z}} q_k(y) e^{ikx}.$$

The eigenvalue problem for $(\phi_k,\xi_k,q_k)$ is

$$(\lambda + \nu k^2)\phi_k(y) - \nu \phi_k''(y) = ikq_k(y)$$

$$(\lambda + \nu k^2)\xi_k(y) - \nu \xi_k''(y) = q_k'(y)$$

$$(2.3)$$

$$ik\phi_k(y) + \xi_k'(y) = 0$$

$$\phi_k(0) = \phi_k(1) = \xi_k(0) = \xi_k(1) = 0.$$ 

The cases $k \neq 0$ and $k = 0$ need to be considered separately.

For $k \neq 0$ we have

$$\nu \xi_k''(y) - (\lambda + 2\nu k^2)\xi_k''(y) + k^2(\lambda + \nu k^2)\xi_k(y) = 0 \quad \text{in} \quad (0,1)$$

$$\xi_k(0) = \xi_k(1) = \xi_k'(0) = \xi_k'(1) = 0.$$ 

(2.4)
The eigenvalue problem for \((\phi_k, \xi_k, q_k)\) when \(k = 0\) is
\[
\begin{align*}
\lambda \phi_0(y) - \nu \phi_0'(y) & = 0, \\
\lambda \xi_0(y) - \nu \xi_0'(y) & = \nu \phi_0(y), \\
\xi_0(y) & = 0, \\
\phi_0(0) & = \phi_0(1) = \xi_0(0) = \xi_0(1) = 0.
\end{align*}
\]
(2.5)

We have
\[
\xi_0 = 0, \nu_0 = C, \phi_0(y) = D \sin(n\pi y), \lambda = -\nu \pi^2 n^2, n \in \mathbb{N}.
\]

Since \((D \sin(n\pi y), 0, 0)\) is a solution of the eigenvalue problem (2.5) for eigenvalue \(\lambda = -\nu \pi^2 n^2, n \in \mathbb{N}\), the solution of (1.2) with control zero and initial condition \((D \sin(n\pi y), 0)\), for any \(n \in \mathbb{N}\), is
\[
(u(x, y, t), v(x, y, t), p(x, y, t)) = e^{-\nu \pi^2 n^2 t} (D \sin(n\pi y), 0, C).
\]

Thus, the solution is exponentially decaying at the rate \(-\nu \pi^2\). But we cannot get any arbitrary decay for the system (1.5) using only the normal control \(\psi\) and the mode for \(k = 0\) is not null controllable. To control it, we would require some additional tangential control.

The following lemma summarizes some elementary facts about the eigenvalues and eigenfunctions for nonzero \(k\).

**Lemma 2.2.** We have the following results regarding the spectrum of the linear operator associated to (2.3) and its eigenfunctions.

1. The spectrum of the linear operator associated to (2.3) is real. The resolvent of the linear operator associated to (2.3) is compact and hence its spectrum consists of a set of isolated eigenvalues.

2. If \(\lambda \geq -\nu k^2\), for all \(k \in \mathbb{Z}, k \neq 0\), then \(\xi_k = 0\) for all \(k \neq 0\). Thus, the spectrum of the linear operator associated to (2.3) is a subset of \((-\infty, -\frac{4\pi^2}{\nu^2} \nu)\) and in particular, eigenvalues for the \(k\)th mode satisfy \(\lambda_k < -\nu k^2\) for all \(k \in \mathbb{Z} - \{0\}\).

   In the following, let \(l\) be a natural number which counts the eigenvalues for fixed \(k\) in order of increasing magnitude. Since we have \(\lambda_k < -\nu k^2\), we may set \(\tilde{\mu}_{k,l} = \sqrt{-(k^2 + \frac{\lambda_k}{\nu})}\), and we have \(\tilde{\mu}_{k,l} \in \mathbb{R}^+\).

3. For all \(k \in \mathbb{Z} - \{0\}\), \(\{\lambda_{k,l}, \phi_{k,l}, \xi_{k,l}, q_{k,l}\}_{l \in \mathbb{N}}\) is the solution of the eigenvalue problem (2.3), where
\[
\xi_{k,l}(y) = C_1(\lambda_{k,l}) e^{ky} + C_2(\lambda_{k,l}) e^{-ky} + C_3(\lambda_{k,l}) e^{\mu_{k,l} y} + C_4(\lambda_{k,l}) e^{-\mu_{k,l} y},
\]
(2.6)
and, for all \(k \in \mathbb{Z} - \{0\}\) and for all \(l \in \mathbb{N}\), \(\lambda_{k,l}\) satisfies
\[
\det \begin{pmatrix} 1 & 1 & 1 & 1 \\ k & -k & \mu_{k,l} & -\mu_{k,l} \\ e^k & e^{-k} & e^{\mu_{k,l}} & e^{-\mu_{k,l}} \\ ke^k & -ke^{-k} & \mu_{k,l}e^{\mu_{k,l}} & -\mu_{k,l}e^{-\mu_{k,l}} \end{pmatrix} = 0,
\]
where \(\mu_{k,l} = i\tilde{\mu}_{k,l}\), and \(\lambda_{k,l} < -\nu k^2\) is necessary for a nontrivial solution.

Further, \(\{\phi_{k,l}, \xi_{k,l}\}_{l \in \mathbb{N}}\) is an orthogonal family in \(L^2(0, 1)\).
Lemma 2.3. The solution of (2.7) for all $k \in \frac{2\pi}{L}Z - \{0\}$ satisfies:

1. For any small $\delta > 0$, there exists a (sufficiently large) $k_0 \in \mathbb{N}$, such that for all $k \in \frac{2\pi}{L}Z - \{0\}$ with $|k| \geq k_0$, we have the following:
   a) If any root $\tilde{\mu}_{k,j}$ of (2.7), with $|k| \geq k_0$ and some $j \in \mathbb{N}$, satisfies $|\tilde{\mu}_{k,j}^2 - \frac{1}{2k^2}| < \delta$, then it is unique between two consecutive zeros of $\sin(\cdot)$.
   b) If the root $\tilde{\mu}_{k,j}$ of (2.7), with $|k| \geq k_0$ and some $j \in \mathbb{N}$ satisfies $|\tilde{\mu}_{k,j}^2 - \frac{1}{2k^2}| \geq \delta$, then it is unique between two consecutive zeros of $\cos(\cdot)$.
   c) Moreover, $k_0$ can be chosen large enough such that the gap between two consecutive roots of (2.7) for $k \in \frac{2\pi}{L}Z - \{0\}$ with $|k| \geq k_0$ is always greater than $\pi - \epsilon_0$, for some positive small constant $\epsilon_0 > 0$.
   d) There exists a unique root $\mu_{k,l}$ in $(l\pi, (l+1)\pi)$, for all $l \in \mathbb{N}$.

2. For all $k \in \frac{2\pi}{L}Z - \{0\}$, $k \neq 0$ and $|k| < k_0$, there exist $l_k \in \mathbb{N}$ and $N_k \in \mathbb{N}$, where $N_k$ is the number of roots of (2.7) in $(0, (l_k+1)\pi - \frac{\pi}{4})$, and the following hold:
   a) for all $l \geq l_k + 1$, there exists a unique root $\tilde{\mu}_{k,j}$ of (2.7) in the ball $B(l\pi, \pi/4)$, where $j = l + N_k - l_k$ and the root in fact lies in the interval $(l\pi - \pi/4, l\pi + \pi/4)$.
   b) there is no root $\tilde{\mu}$ of (2.7) between $\tilde{\mu}_{k,j}$ and $\tilde{\mu}_{k,j+1}$, where $j = l + N_k - l_k$, for $l \geq l_k + 1$.
   c) $\tilde{\mu}_{k,l+N_k-l_k} - l\pi \to 0$ as $l \to \infty$.

3. For each fixed $k \in \frac{2\pi}{L}Z - \{0\}$ and for all $l \in \mathbb{N}$, $\mu_{k,l}$, the root of (2.7) is simple.

4. For any $k \in \frac{2\pi}{L}Z - \{0\}$, there exists a $l_0 \in \mathbb{N}$, independent of $k$, such that $\mu_{k,j} > j\pi/4$, for all $j > l_0$.

5. The solution $\mu_{k,l}$ of (2.7) corresponds to $\frac{\lambda_{k,l}}{L} = -\tilde{\mu}_{k,l}^2 - k^2$ for all $k \in \frac{2\pi}{L}Z - \{0\}$ and for all $l \in \mathbb{N}$. For each fixed $k \in \frac{2\pi}{L}Z - \{0\}$, and for all $l \in \mathbb{N}$, $\lambda_{k,l}$ is a solution of the eigenvalue problem (2.3) with multiplicity one and there exist positive constants $C_1$ and $C$ independent of $k,l$, such that

$$\inf_{k,l} \{\lambda_{k,l} - \lambda_{k,l+1}\} > C > 0,$$

and

$$\sum_{l > l_0} \frac{1}{(-\lambda_{k,l})} < C_1 \sum_{l > l_0} \frac{1}{l^2} < \infty,$$

where $l_0$ is introduced in the previous property.

Proof. 1.a) We consider the following rearrangement of (2.7):

$$f(\mu) = \frac{1}{\cosh(k)} - \cos(\mu) - \frac{\sinh(k)}{\cosh(k)} \frac{\mu^2 - 1}{2k^2}. \quad (2.8)$$
We see that between any two consecutive zeros of \( \sin(\cdot) \), \( f \) changes its sign, since, for all \( l \in \mathbb{N} \), we have

\[
f((l+1)\pi) = \frac{1}{\cosh(k)} - \cos((l+1)\pi), \quad f(l\pi) = \frac{1}{\cosh(k)} - \cos(l\pi),
\]

and \( \frac{1}{\cosh(k)} \) is small if \( |k| \geq k_0 \), and \( k_0 \) is chosen large enough. Hence, there exists a root of (2.8) between two consecutive zeros of \( \sin(\cdot) \).

Let us assume that the root of (2.7), denoted by \( \tilde{\mu}_{k,j} \), for some \( j \in \mathbb{N} \), satisfies \( \left| \frac{\tilde{\mu}_{k,j}^2}{k} - 1 \right| < \delta \), where \( \delta > 0 \) is small enough, and \( k \in \mathbb{Z} \) satisfying \( |k| \geq k_0 \), where \( k_0 \) is large enough chosen later. We claim that, for large enough \( k_0 \) and small enough \( \delta \), this root is unique. For any \( \epsilon > 0 \), choosing \( k_0 \) large enough and \( \delta \) small enough, we get that, any zero of \( f(\cdot) \) satisfying \( \left| \frac{\mu^2}{k} - 1 \right| < \delta \), obeys \( |\cos(\mu)| < \epsilon \), and hence this \( \mu \) must belong to a small neighbourhood \( N_\epsilon \) (with radius \( 0 < \epsilon < \pi/4 \)) of the zero of \( \cos(\cdot) \) between two consecutive zeros of \( \sin(\cdot) \). Now, if there are multiple zeros of \( f(\cdot) \) between two consecutive zeros of \( \sin(\cdot) \) satisfying \( \left| \frac{\mu^2}{k} - 1 \right| < \delta \), the zeros of \( f(\cdot) \) will be in the neighbourhood \( N_\epsilon \), and between two zeros of \( f(\cdot) \), there must be a zero of \( f'(\cdot) \) in \( N_\epsilon \). Further, we check

\[
f'(\mu) = \sin(\mu) - \frac{\sinh(k)}{\cosh(k)} \left[ \cos(\mu) \left( \frac{\mu^2}{k^2} - 1 \right) + \frac{\sin(\mu)}{k} \left( 1 - \frac{\mu^2}{k^2} - 1 \right) \right],
\]

and the zeros of \( f'(\cdot) \) are in a small neighbourhood of the zeros of \( \sin(\cdot) \) due to the choice of \( k_0 \) and \( \delta \) and we can make that the neighborhoods around the zeros of \( \sin(\cdot) \) and \( N_\epsilon \) disjoint by a suitable refinement of \( k_0 \) and \( \delta \), if necessary. Thus, \( f'(\cdot) \) cannot have any zeros in \( N_\epsilon \), and hence there exists unique zero of \( f(\cdot) \) between two consecutive zeros of \( \sin(\cdot) \).

1.b) Now let the root \( \tilde{\mu}_{k,j} \) for some \( j \in \mathbb{N} \) and for all \( |k| \geq k_0 \), where \( k_0 \) is large enough, satisfy \( \left| \frac{\tilde{\mu}_{k,j}^2}{k} - 1 \right| \geq \delta \), where \( \delta \) is as mentioned above. At the two consecutive zeros of \( \cos(\cdot) \), from (2.8), it follows that for \( j = m - 1, m \), where \( m \in \mathbb{N} \),

\[
f((2j+1)\pi/2) = \frac{1}{\cosh(k)} - \frac{\sinh(k)}{\cosh(k)} \sin((2j+1)\pi/2) = \frac{(2j+1)^2\pi^2/4}{k} - 1 - \frac{1}{2}\frac{(2j+1)\pi/2}{k}.
\]

Choosing \( k_0 \) large enough in the above relation such that for all \( |k| \geq k_0 \), and \( \pi/k \) are small enough, we get that \( f \) changes sign between two consecutive zeros of \( \cos(\cdot) \). To prove that \( \tilde{\mu}_{k,j} \) satisfying \( \left| \frac{\tilde{\mu}_{k,j}^2}{k^2} - 1 \right| \geq \delta \) is the unique root of (2.7) between two consecutive zeros of \( \cos(\cdot) \), we notice that any nonzero roots of (2.7) satisfy

\[
\frac{\sin(\mu)(\sinh(k)/\cosh(k))}{(1/\cosh(k)) - \cos(\mu)} - 2 \frac{\mu/k}{(\mu^2/k^2) - 1} = 0,
\]

and for any \( \epsilon > 0 \), there exists \( k_0 \), large enough, such that for all \( |k| \geq k_0 \), between two consecutive zeros of \( \cos(\cdot) \), the zeros of (2.9) satisfy

\[
\left| \tan(\mu) + 2 \frac{\cosh(k)}{\sinh(k)} \frac{\mu/k}{(\mu^2/k^2) - 1} \right| = \left| \tan(\mu) + \frac{\sin(\mu)}{(1/\cosh(k)) - \cos(\mu)} \right| < \epsilon.
\]
Now, if (2.9) has multiple roots between two consecutive zeros of \( \cos(\cdot) \), as argued in the first part, \( f'(\cdot) \) should have zeros between any two consecutive zeros of \( f(\cdot) \). From the representation of \( f'(\cdot) \), we see that for \( \mu \), any zero of \( f'(\cdot) \), \( \tan(\mu) \) satisfies

\[
\left| \tan(\mu) - \frac{\sinh(k) \mu^2 / k^2 - 1}{\cosh(k)} \right| < \epsilon, \quad \forall |k| \geq k_0 \tag{2.11}
\]

for any arbitrary \( \epsilon > 0 \), choosing \( k_0 \) large enough. In any interval between two consecutive roots of \( \cos(\cdot) \), there is one subinterval where \( \tan \mu + \frac{\cosh(k)}{\sinh(k)} \frac{2\mu/k}{\mu^2/k^2 - 1} \) is small. But within that subinterval, \( \tan \mu - \frac{\sinh(k) (\mu^2/k^2) - 1}{\cosh(k)} \frac{2\mu/k}{\mu^2/k^2 - 1} \) cannot be also small. Hence, (2.7) has a unique zero between two consecutive zeros of \( \cos(\cdot) \).

1.c Let us assume that \( |k| \geq k_0 \) and \( k_0 \) is large enough. If \( \tilde{\mu}_{k,j} \), the root of (2.7) is such that \( |\tilde{\mu}_{k,j}/k| \) is close to 1, then the roots are close to the zeros of \( \cos(\cdot) \) and hence they are approximately \( \pi \) apart. If \( |\mu/k| \) is not close to 1, the roots are close to those of \( \tan \mu = -2 \frac{\cosh(k) - (\mu/k)}{\sinh(k)} (\mu^2/k^2 - 1) \). For large \( k \), \( \cos k / \sinh k \) is close to 1, and \( \mu/k \) changes slowly with \( \mu \). Hence \( \tan \mu \) changes little between successive roots. Therefore, the roots in this case are also spaced approximately \( \pi \) apart.

1.d Since, for all \( |k| \geq k_0 \), where \( k_0 \) is large enough, \( f \), defined in (2.8), changes sign between two consecutive zeros of \( \sin(\cdot) \), there can be an odd number of roots of (2.7) between two consecutive zeros of \( \sin(\cdot) \). Now, by 1.c, we have that the gap between two consecutive roots of (2.8) is greater than \( \pi - \epsilon_0 \). Choosing \( 0 < \epsilon_0 < \pi/2 \), we can derive that each interval \( (l\pi, (l + 1)\pi) \), for all \( l \in \mathbb{N} \), contains a unique root of (2.7) and we denote the root by \( \tilde{\mu}_{k,l} \). This argument does not apply to the interval \((0, \pi)\), since at \( \tilde{\mu} = 0 \), there is a zero in the denominator of the last term in (2.8). For large \( k \), the dominant terms in \( f \) are

\[-\cos(\tilde{\mu}) + k \frac{\sin(\tilde{\mu})}{2\mu}.
\]

The second term in this expression is positive and it dominates except near \( \tilde{\mu} = \pi \), where \( -\cos \tilde{\mu} \) is also positive. Hence the expression is strictly positive on the entire interval \([0, \pi]\), and it is easy to show that for large \( k \) the perturbing terms do not change that. Hence there is no root between 0 and \( \pi \).

2. For all \( k \in \mathbb{Z} - \{0\} \), \( k \neq 0 \) and \( |k| < k_0 \), we get that there exists a positive natural number \( l_k \) such that

\[
-2k^2 |1 - \cosh(k) \cos(z)| - k^2 \sin(z) \sinh(k) \leq |\sin(z) \sinh(k)||z|^2, \quad \forall z \in \partial B(l\pi, \pi/4), \forall l > l_k.
\]

This inequality holds for large enough \( l \) since \( |z^2| \gg |z| \), and \( |\sin z / \cos z| \) is bounded below on the periphery of the circle. Comparing the solutions of (2.7) with the solutions of \( |\sinh(k) \sin(z)| z^2 \), by Rouché’s theorem, we obtain that for all \( k \in \mathbb{Z} - \{0\} \), \( k \neq 0 \) and \( |k| < k_0 \) and for all \( l > l_k \), there exists a unique solution of (2.7) in the ball \( B(l\pi, \pi/4) \), which in fact lies in the interval \((l\pi - \pi/4, l\pi + \pi/4)\) as Property 1. of Lemma 2.2 gives that all roots of (2.7) are real. The other results also can be derived by comparing the solution of (2.7) for all \( k \in \mathbb{Z} - \{0\} \), \( k \neq 0 \) and \( |k| < k_0 \) and for all \( l > l_k \) with the zeros of \( |\sinh(k) \sin(z)| z^2 \).
3. For a \( k \in \frac{2\pi}{L} \mathbb{Z} - \{0\} \), if \( \mu \) is a multiple root of (2.7), then there exist two solutions \( \xi_{k,1} \) and \( \xi_{k,2} \) of the eigenvalue problem (2.4) for the eigenvalue \( \mu \). By choosing the constants \( d_1 \) and \( d_2 \), appropriately, we get that \( \xi = d_1 \xi_{k,1} + d_2 \xi_{k,2} \), satisfying \( \xi''(0) = 0 \). Since, \( \xi \) satisfies (2.4) for the same \( \mu \), by Property 3. in Lemma 2.2, we have that
\[
\xi(y) = a_1 \cosh(ky) + b_1 \cos(\mu y) + a_2 \sinh(ky) + b_2 \sin(\mu y), \quad \forall y \in (0, 1).
\]
Using \( \xi(0) = 0 = \xi''(0) \), we get that for all \( y \in (0, 1) \), \( \xi(y) = a_2 \sinh(ky) + b_2 \sin(\mu y) \). From \( \xi''(0) = 0 = \xi'(1) \), it can be derived that \( \cosh(k) = \cos(\mu) \).
\[\text{This is a contradiction because of } \cosh(k) > 1 \text{ for all } k \neq 0 \text{ and } \cos(\mu) \leq 1.\]
Thus, \( \mu \) has to be a simple root of (2.7).

4. From 1.d) we have that if \( k_0 \) is large enough and \( |k| \geq k_0 \), then \( \tilde{\mu}_{k,j} \), the solution of (2.7), belongs to \( (j\pi, (j+1)\pi) \) and hence \( \tilde{\mu}_{k,j} > j\pi/2 \), for all \( j \geq 1 \) and \( |k| \geq k_0 \).

Now for each \( k \in \frac{2\pi}{L} \mathbb{Z} - \{0\} \) and \( |k| < k_0 \), from 2.a), it follows that \( \tilde{\mu}_{k,j} \) belongs to \( ((j - N_k + l_k)\pi - \pi/4, (j - N_k + l_k)\pi + \pi/4) \) and so \( \tilde{\mu}_{k,j} > (j - N_k + l_k)\pi - \pi/4 \), where \( N_k \) and \( l_k \) are introduced in 2.a). Let us choose \( N_0 = \max\{N_k \mid |k| < k_0, \quad k \neq 0\} \). Then, \( k \in \frac{2\pi}{L} \mathbb{Z} - \{0\} \) and \( |k| < k_0 \) and for all \( j > 2N_0 \), we get that
\[
\tilde{\mu}_{k,j} > (j - N_k + l_k)\pi - \pi/4 > (j - N_0)\pi - \pi/4 > j\pi/2 - \pi/4 > j\pi/4.
\]
Choosing \( l_0 = 2N_0 \), we get our result.

5. Using all the above results, the claim follows.

\[\Box\]

**Lemma 2.4.** Let us recall that \( \{\phi_{k,l}, \xi_{k,l}, q_{k,l}\}_{l \in \mathbb{N}} \) is the solution of the eigenvalue problem (2.3) corresponding to the eigenvalue \( \lambda_{k,l} \). We have the following explicit expression for the eigenfunctions \( \{\phi_{k,l}, \xi_{k,l}, q_{k,l}\} \):

1. **The coefficients in the expression of \( \xi_{k,l} \) are**
\[
\begin{align*}
C_1(\lambda_{k,l}) &= \mu_{k,l}^2 \left[ e^{-\mu_{k,l}+k} - e^{\mu_{k,l}-k} \right] + \mu_{k,l} \left[ 2k - k \left( e^{-\mu_{k,l}+k} + e^{\mu_{k,l}-k} \right) \right], \\
C_2(\lambda_{k,l}) &= \mu_{k,l}^2 \left[ e^{\mu_{k,l}+k} - e^{-\mu_{k,l}-k} \right] + \mu_{k,l} \left[ 2k - k \left( e^{\mu_{k,l}+k} + e^{-\mu_{k,l}-k} \right) \right], \\
C_3(\lambda_{k,l}) &= \mu_{k,l} \left[ 2k - k \left( e^{\mu_{k,l}+k} + e^{-\mu_{k,l}-k} \right) \right] + k^2 \left[ e^{\mu_{k,l}+k} - e^{-\mu_{k,l}-k} \right], \\
C_4(\lambda_{k,l}) &= \mu_{k,l} \left[ 2k - k \left( e^{\mu_{k,l}+k} + e^{-\mu_{k,l}-k} \right) \right] + k^2 \left[ e^{\mu_{k,l}+k} - e^{-\mu_{k,l}-k} \right].
\end{align*}
\]

2. **For all \( k \in \frac{2\pi}{L} \mathbb{Z} - \{0\} \) and \( l \in \mathbb{N} \), \( q_{k,l}(1) = -\frac{\nu}{\kappa} \xi'''_{k,l}(1) \), where**
\[
\xi'''_{k,l}(1) = -4k \frac{\lambda_{k,l}}{\nu} \left[ \mu_{k,l} \left\{ \frac{2k}{\sinh(k)} \left( 1 - \cosh(k) \cos(\mu_{k,l}) \right) + k \sinh(k) \right\} \right] + k^2 \sin(\mu_{k,l}).
\]

**Lemma 2.5.** Let \( (\phi, \xi) \in V_{L,n}^0(\Omega) \). Then we have
\[
\left( \phi(x,y), \xi(x,y) \right) = \sum_{k \in \frac{2\pi}{L} \mathbb{Z}} \sum_{l \in \mathbb{N}} \alpha_{k,l} \left( \phi_{k,l}(y), \xi_{k,l}(y) \right) e^{ikx},
\]
where \( \{\phi_{k,l}, \xi_{k,l}\}_{k \in \frac{2\pi}{L} \mathbb{Z}, l \in \mathbb{N}} \) are the eigenfunctions associated to the eigenvalue problem (2.3)-(2.5).
We have the following existence theorem for the solution of (1.5).

**Theorem 2.6.** Let $T > 0$. For any $U_0 \in V^0_{\sharp,n}(\Omega)$ with $\int_0^L U_0(x,y) \, dx = 0$, for all $y \in (0,1)$ and for any $\psi \in L^2(0,T;\dot{L}^2(0,L))$, system (1.5) admits a unique solution $U$ in $C([0,T];V^{-1}_\sharp(\Omega))$ with $\int_0^L U(x,y,t) \, dx = 0$, for all $(y,t) \in (0,1) \times (0,T)$.

Further, if $\psi$ vanishes near $t = T$, then the solution of (1.5) at $t = T$, $U(T)$ is smooth and in particular in $V^0_{\sharp,n}(\Omega)$.

**Remark 1.**
1. We note that $\int_0^L v_0(x,y) \, dx$ is automatically zero due to the boundary condition at the bottom wall and the incompressibility condition. Hence the condition on the average of $U_0 = (u_0,v_0)$ is really just a condition on $u_0$.
2. We do not claim that the regularity of the solution as stated in the preceding theorem is optimal (for a more careful discussion of regularity for solutions of inhomogeneous Stokes problems, see [14]).
3. If we only know $U \in C([0,T],V^{-1}_\sharp(\Omega))$, we can interpret the vanishing of the integral over $x$ as the vanishing of the $k = 0$ Fourier component. However, for $t > 0$ and $y < 1$, $U$ is actually of class $C^\infty$, and the integral is defined in the classical sense.

3. **Null controllability.** In this section, we study the null controllability of system (1.5). In particular, we have the following result:

**Theorem 3.1.** Let $T > 0$. For any $U_0 \in V^0_{\sharp,n}(\Omega)$ with $\int_0^L U_0(x,y) \, dx = 0$, for all $y \in (0,1)$, there exists a control $\psi \in L^2(0,T;\dot{L}^2(0,L))$, such that the solution of (1.5) reaches zero at $t = T$.

To prove the above theorem, it is enough to show the following result holds.

**Proposition 1.** Let $T > T_0 > 0$. Let us assume that there exists an operator $B \in \mathcal{L}(L^2(0,T_0;\dot{L}^2(0,L)),V^0_{\sharp,n}(\Omega))$ such that

$$B(q(\cdot,1,\cdot)|_{(0,L)\times(0,T_0)}) = \Phi(\cdot,\cdot,0),$$

where $(\Phi,q)$ is the solution of the adjoint problem (2.1) with terminal condition $\Phi_T \in V^0_{\sharp,n}(\Omega)$ with $\int_0^L \Phi_T(x,y) \, dx = 0$, for all $y \in (0,1)$. Set

$$\psi = \begin{cases} B^*U_0 & \text{in } (0,L) \times (0,T_0), \\ 0 & \text{in } (0,L) \times [T_0,T]. \end{cases}$$

(3.2)

Then, for any $T > 0$ and for any $U_0 \in V^0_{\sharp,n}(\Omega)$ with $\int_0^L U_0(x,y) \, dx = 0$, for all $y \in (0,1)$, $U$, the solution of (1.5) with control $\psi$ defined in (3.2) and initial condition $U_0$, reaches zero at $t = T$. 

Proof. Let us note that since \( \psi \), defined in (3.2), vanishes near \( T \), from the last part of Theorem 2.6, it follows that at \( t = T \), \( U(\cdot) \), the solution of (1.5) with control \( \psi \), is in \( L^2_T(\Omega) \) (in fact \( C^\infty \) smooth). Multiplying (1.5) with \( \Phi \), the solution of the adjoint problem (2.1) with terminal condition \( \Phi_T \in \mathbf{V}^0_{\frac{x}{T},n}(\Omega) \) with \( \int_0^L \phi_T(x,y) \, dx = 0 \), for all \( y \in (0,1) \), and using an integration by parts, we obtain the identity

\[
\int_0^T \int_0^L \psi(x,t)q(x,1,t) \, dx \, dt = \langle U_0(\cdot,\cdot), \Phi(\cdot,\cdot,0) \rangle_{L^2_T(\Omega)} - \langle U(\cdot,\cdot,T), \Phi_T(\cdot,\cdot) \rangle_{L^2_T(\Omega)}. \tag{3.3}
\]

Now, using \( \psi \) defined in (3.2), from (3.3), we obtain

\[
\langle U(\cdot,\cdot,T), \Phi_T(\cdot,\cdot) \rangle_{L^2_T(\Omega)} = 0, \quad \forall \Phi_T \in \mathbf{V}^0_{\frac{x}{T},n}(\Omega),
\]

and hence \( U(\cdot,\cdot,T) = 0 \). \( \square \)

Remark 2. 1. We note that only the pressure \( q \) appears in the normal component of stress. The viscous stress vanishes as a result of the divergence condition.

2. We have introduced \( T_0 < T \) only to avoid any technical issues related to lack of regularity of the solution of the adjoint equation. By choosing \( T_0 < T \), we ensure that the solutions of the adjoint problem are in fact \( C^\infty \) smooth for \( t \in [0,T_0] \). Therefore, at any time, either \( U \) or \( \Phi \) is \( C^\infty \) smooth in the preceding proposition. Choosing \( T > T_0 \) also guarantees that the integral of \( ||q||^2 \) in the following proposition is finite. We note that a posteriori it is clear that \( U \) in Proposition 1 actually vanishes at \( T_0 \), since backward uniqueness holds for the Stokes equations.

Next we prove the existence of the bounded operator \( B \), defined in (3.1), by showing that the observability inequality associated to the null control problem of (1.5) holds.

**Proposition 2.** Let us assume that \( B \) is as defined by (3.1). For any \( T > T_0 > 0 \), \( B \in \mathcal{L}(L^2(0,T_0;L^2(0,L)), L^2_T(\Omega)) \), i.e, there exists a positive constant \( C(T_0) > 0 \), such that

\[
\int_0^{T_0} ||q(\cdot,1,t)||_{L^2(0,L)}^2 \, dt \geq C(T_0)||\phi,\xi(\cdot,\cdot,0)||_{L^2_T(\Omega)}^2, \tag{3.4}
\]

where \((\phi,\xi,q)\) is the solution of (2.1) with terminal condition \((\phi_T,\xi_T) \in \mathbf{V}^0_{\frac{x}{T},n}(\Omega)\) satisfying \( \int_0^L \phi_T(x,y) \, dx = 0, \quad \forall y \in (0,1) \).

Let us consider the series expansion of \((\phi,\xi,q)\)

\[
\phi(x,y,t) = \sum_{k \in \frac{2\pi}{L}Z - \{0\}} \phi_k(y,t)e^{ikx}, \quad \xi(x,y,t) = \sum_{k \in \frac{2\pi}{L}Z - \{0\}} \xi_k(y,t)e^{ikx},
\]

\[
q(x,y,t) = \sum_{k \in \frac{2\pi}{L}Z - \{0\}} q_k(y,t)e^{ikx}, \tag{3.5}
\]

\[
\phi_T(x,y) = \sum_{k \in \frac{2\pi}{L}Z - \{0\}} \sum_{l \in \mathbb{N}} \alpha_{k,l} \phi_{k,l}(y)e^{ikx},
\]

\[
\xi_T(x,y) = \sum_{k \in \frac{2\pi}{L}Z - \{0\}} \sum_{l \in \mathbb{N}} \alpha_{k,l} \xi_{k,l}(y)e^{ikx},
\]
Lemma 3.2. Let us recall from Lemma 2.4, the representation of \( \xi_{k,l} \) for all \( k \in \frac{2\pi}{L}Z - \{0\} \) and \( l \in \mathbb{N}. \) There exists a positive constant \( M, \) independent of \( k \) and \( l, \) such that
\[
|\xi_{k,l}'''(1)| \geq Mk^2 e^{|k|}|\lambda_{k,l}| |\mu_{k,l}|.
\]
(3.7)

Proof. From Lemma 2.4, since we have
\[
\xi_{k,l}''' = -i4k \frac{\lambda_{k,l}}{\nu} \left[ \frac{2k}{\sinh(k)}(1 - \cosh(k) \cos(\mu_{k,l})) + k \sinh(k) \right] + k^2 \sin(\mu_{k,l}),
\]
then we get:

1. There exists a large \( \tilde{k} \in \mathbb{N}, \) such that for all \( |k| > \tilde{k} \) and for all \( l \in \mathbb{N}, \) we have
\[
|\xi_{k,l}'''(1)| \geq M_* k^2 e^{|k|}|\lambda_{k,l}| |\mu_{k,l}|,
\]
for some \( M_* > 0. \)

2. For \( |k| \leq \tilde{k}, \) \( k \neq 0, \) using the fact that \( \tilde{\mu}_{k,l} - (l - N_k + l_k)\pi \to 0 \) as \( l \to \infty \) from 2.c) in Lemma 2.3, we find positive constants \( l_k \) and \( \tilde{M}_k, \) independent of \( l, \) such that
\[
|\xi_{k,l}'''(1)| \geq \tilde{M}_k k^2 e^{|k|}|\lambda_{k,l}| |\mu_{k,l}|, \quad \forall l > \tilde{k}.
\]

To see this, we use the following estimate:
\[
|\frac{2}{\sinh(k)}(1 - \cosh(k) \cos(\tilde{\mu}_{k,l})) + \sinh(k)| \geq \frac{2 + \sinh^2 k - 2 \cosh k}{|\sinh k|} = \frac{(\cosh k - 1)^2}{|\sinh k|}.
\]
(3.8)

This also shows that \( \xi_{k,l}'''(1) \neq 0 \) for all \( k \in \frac{2\pi}{L}Z - \{0\}, \) and \( l \in \mathbb{N} \) (see also Lemma 4.1 in [12] and Proposition 2.1 in [6]). Thus there exists a positive \( M_k, \) independent of \( l, \) such that
\[
|\xi_{k,l}'(1)| \geq M_k k^2 e^{|k|}|\lambda_{k,l}| |\mu_{k,l}|, \quad \forall l \in \mathbb{N}, \quad \forall |k| \leq \tilde{k}, \ k \neq 0.
\]
3. Finally, taking \( M = \min\{M_n, M_k, |k| \leq \hat{k}, k \neq 0\} \) (which is a positive number), we obtain that

\[
|\xi_{k,l}(1)| \geq M k^2 e^{|k|} |\lambda_{k,l}| |\mu_{k,l}|, \quad \forall k \in \mathbb{Z} - \{0\}, \quad \forall l \in \mathbb{N}.
\]

**Lemma 3.3.** For any \( T > T_0 > 0 \), there exists a positive constant \( C(T_0) > 0 \), independent of \( k \), such that for all \( k \in \frac{2\pi}{L} \mathbb{Z} - \{0\} \),

\[
\int_0^{T_0} |q_k(1,t)|^2 dt \geq C(T_0) \| (\phi_k, \xi_k)(\cdot, 0) \|_{L^2(0,1)}^2,
\]

where \((\phi_k, \xi_k, q_k)\) is the solution of (3.6) with terminal condition \((\phi_k(\cdot, T), \xi_k(\cdot, T)) \in (L^2(0,1))^2\).

**Proof.** From (3.6), we can derive that

\[
\phi_k(y,t) = \sum_{l \in \mathbb{N}} \alpha_{k,l} e^{\lambda_{k,l}(T-t)} \phi_{k,l}(y), \quad \xi_k(y,t) = \sum_{l \in \mathbb{N}} \alpha_{k,l} e^{\lambda_{k,l}(T-t)} \xi_{k,l}(y).
\]

Now using the representation of the eigenfunctions \( \{\phi_{k,l}, \xi_{k,l}\}_{l \in \mathbb{N}} \) from Lemma 2.2, we obtain that there exists a positive constant \( M \) independent of \( k \) such that

\[
\| \phi_k(\cdot, 0), \xi_k(\cdot, 0) \|_{L^2(0,1)}^2 \leq M \sum_{l \in \mathbb{N}} |\alpha_{k,l}|^2 e^{2\lambda_{k,l} T} |\lambda_{k,l}|^2 |\mu_{k,l}|^2.
\]

From (3.6), using the boundary condition \( \phi_k(1) = 0 \), we obtain

\[
\nu k q_k(1) = -\nu \phi''_k(1),
\]

and by combining this with the incompressibility condition, we find

\[
q_k(1) = -\frac{\nu}{k^2} \xi'''_k(1).
\]

Hence, we get that for all \( k \in \frac{2\pi}{L} \mathbb{Z} - \{0\} \),

\[
q_k(1, t) = -\frac{\nu}{k^2} \sum_l \alpha_{k,l} e^{\lambda_{k,l}(T-t)} \xi'''_{k,l}(1),
\]

and from the expression of 2. in Lemma 2.4, we have that

\[
\xi_{k,l}(1) = -4k \frac{\lambda_{k,l}}{\nu} \left[ \mu_{k,l} \left\{ \frac{2k}{\sinh(k)} (1 - \cosh(k)\cos(\mu_{k,l})) + k \sinh(k) \right\} + k^2 \sin(\mu_{k,l}) \right]
\]

and from Lemma 3.2, we have (3.7), i.e.,

\[
|\xi_{k,l}(1)| \geq M k^2 e^{|k|} |\lambda_{k,l}| |\mu_{k,l}|, \quad \forall k \in \mathbb{Z} - \{0\}, \quad \forall l \in \mathbb{N},
\]

for some positive constant \( M \). Since, by Lemma 2.3, we have that

\[
\inf_{k,l \neq 0} \{\lambda_{k,l} - \lambda_{k,l+1}\} > C, \quad \sum_{l > l_0} \frac{1}{(-\lambda_{k,l})} < \sum_{l > l_0} \frac{1}{T^2} < \infty,
\]

where \( C \) and \( l_0 \) are independent of \( k \), by using a Müntz-Szász theorem (see [11], Proposition 3.2), we can show that

\[
\int_0^{T_0} \left| \frac{\nu}{k^2} \sum_l \alpha_{k,l} e^{\lambda_{k,l}(T-t)} \xi'''_{k,l}(1) \right|^2 dt \geq \int_{T_0/2}^{T_0} \left| \frac{\nu}{k^2} \sum_l \alpha_{k,l} e^{\lambda_{k,l}(T-t)} \xi'''_{k,l}(1) \right|^2 dt.
\]

\[
\geq C(T_0) \sum_{l \in \mathbb{N}} |\alpha_{k,l}|^2 / (k^4 |\lambda_{k,l}|) |\xi_{k,l}(1)|^2 e^{2\lambda_{k,l}(T-T_0/2)}.
\]
From (3.10) and (3.7), it follows that
\[ \int_{0}^{T_{0}} |q_k(1,t)|^2 \, dt \geq C(T_{0}) \| \phi_k(\cdot, 0), \xi_k(\cdot, 0) \|_{L^2(0,1)}^2, \]
and hence we get (3.9), since \( \exp(-\lambda_{k,l} T_{0})/|\lambda_{k,l}| > T_{0} \).

**Proof of Proposition 2.** Note that
\[ \int_{0}^{T_{0}} \|q(\cdot, 1, t)\|_{L^2(0,L)}^2 \, dt = L \sum_{k \in \frac{2\pi}{L} \mathbb{Z} - \{0\}} \int_{0}^{T_{0}} |q_k(1,t)|^2 \, dt, \]
and
\[ \| (\phi, \xi)(\cdot, \cdot, 0) \|_{V^0_{1,\alpha}(\Omega)}^2 = L \sum_{k \in \frac{2\pi}{L} \mathbb{Z} - \{0\}} \| \phi_k(\cdot, 0), \xi_k(\cdot, 0) \|_{L^2(0,1)}^2. \]
The result now follows from Lemma 3.3.
