1 Input files

This section shows the input files used in this work for all calculations. The geometry optimisations, on the def2-SVP level of theory, were performed with the following Gaussian input file:

```plaintext
%ProcShared=16
%Mem=38gb
#p B3LYP/Def2SVP opt=tight freq int=ultrafine
0,2
some coordinates
```

All TDDFT calculations were carried out using the following ORCA input file:

```plaintext
! UKS CAM-B3LYP RIJCOSX def2-TZVP def2/J
! XYZFile TightSCF
%scf
MaxIter 1500
end
%maxcore 20000
%pal nprocs 16
end
%tddft
nroots 40
end
* xyz 0 2
some coordinates
* ```
All CASSCF/QD-NEVPT2 calculations were performed using the following ORCA input file:

```plaintext
!RI-JK def2-TZVP NormalPrint MOREAD XYZFILE
%moinp "OrbitalsFromTheTDDFTCalculation.gbw"
%maxcore 20000
%pal nprocs 16 end
%basis
auxC "def2/JK"
auxJK "def2/JK" end
%casscf

* xyz 0 2
some coordinates *
```

S2
2 Benchmark results

For this benchmark, we calculated the exchange interaction $J_{TR}$ for two perylene diimide (PDI) derivatives, which are linked to BPNO radicals. We used different approaches, including restricted open-shell CIS (ROCIS) and CASSCF with and without a QD-NEVPT2 correction. The results can be seen in Figure S1. The CASSCF/QD-NEVPT2 calculation yielded the most reliable results.

![Figure S1: Calculated exchange interactions for two perylene diimide derivatives using different methods.](image)

3 Exchange interactions $J_{TR}$ for the radical series

Figure S2 shows the calculated exchange interactions $J_{TR}$ for the structures of the radical series. As can be seen, the exchange interactions calculated with the def2-TZVP optimised structures are smaller in magnitude than the exchange interactions calculated with the def2-SVP optimised structures, except for the perylene–TEMPO system.

![Figure S2: Calculated exchange interactions for the structures of the radical series.](image)
4 Exchange interactions $J_{TR}$ for the linker series

Figure S3 shows the calculated exchange interactions $J_{TR}$ for the structures of the linker series. We varied the linker length in the perylene–BPNO and –BDPA systems using the def2-SVP basis set for the optimisation of the structures. The calculations predict a reduction in the exchange interaction with increasing length of the phenyl linker.

5 Projection of the target states onto the model space

Here we demonstrate how the target states are projected onto the model space. The starting point is the output file with the energies and wavefunctions of the excited states. As an example, we consider the perylene–phenyl–BPNO system 1. The relevant part of the output can be seen below.

The choice of the target states is not necessarily trivial. Normally the states with the largest coefficients with respect to the model space are taken as target states. In our case, that would include the ground state, which would not be meaningful for the description of the three-center-three-electron problem. Furthermore, the coefficients of the neutral determinants for the ground state would presumably vanish as the active space is increased. Thus, the quartet state and the two doublet states ("Root 1" and "Root 2") come into question. When projecting onto the model space (i.e. the neutral determinants), all ionic determinants are omitted and only the neutral determinants have to be normalised.
