Optimising antimicrobial stewardship interventions in English primary care: a behavioural analysis of qualitative and intervention studies

Aleksandra J. Borek, Marta Wanat, Louise Atkins, Anna Sallis, Diane Ashiru-Oredope, Elizabeth Beech, Christopher C. Butler, Tim Chadborn, Susan Hopkins, Leah Jones, Clodna A. M. McNulty, Nia Roberts, Karen Shaw, Esther Taborn, Sarah Tonkin-Crine

ABSTRACT

Objective While various interventions have helped reduce antibiotic prescribing, further gains can be made. This study aimed to identify ways to optimise antimicrobial stewardship (AMS) interventions by assessing the extent to which important influences on antibiotic prescribing are addressed (or not) by behavioural content of AMS interventions.

Settings English primary care.

Interventions AMS interventions targeting healthcare professionals’ antibiotic prescribing for respiratory tract infections.

Methods We conducted two rapid reviews. The first included qualitative studies with healthcare professionals on self-reported influences on antibiotic prescribing. The influences were inductively coded and categorised using the Theoretical Domains Framework (TDF). Prespecified criteria were used to identify key TDF domains. The second review included studies of AMS interventions. Data on effectiveness were extracted. Components of effective interventions were extracted and coded using the TDF, Behaviour Change Wheel and Behaviour Change Techniques (BCTs) taxonomy. Using prespecified matrices, we assessed the extent to which BCTs and intervention functions addressed the key TDF domains of influences on prescribing.

Results We identified 13 qualitative studies, 41 types of influences on antibiotic prescribing and 6 key TDF domains of influences: ‘beliefs about consequences’, ‘social influences’, ‘skills’, ‘environmental context and resources’, ‘intentions’ and ‘emotions’. We identified 17 research-tested AMS interventions; nine of them effective and four nationally implemented. Interventions addressed all six key TDF domains of influences. Four of these six key TDF domains were addressed by 50%–67% BCTs that were theoretically congruent with these domains, whereas TDF domain ‘skills’ was addressed by 24% of congruent BCTs and ‘emotions’ by none.

Conclusions Further improvement of antibiotic prescribing could be facilitated by: (1) national implementation of effective research-tested AMS interventions (eg, electronic decision support tools, training in interactive use of leaflets, point-of-care testing); (2) targeting important, less-addressed TDF domains (eg, ‘skills’, ‘emotions’); (3) using relevant, under-used BCTs to target key TDF domains (eg, ‘forming/reversing habits’, ‘reducing negative emotions’, ‘social support’). These could be incorporated into existing, or developed as new, AMS interventions.

BACKGROUND

Optimising the use of antimicrobial medicines to control the spread of antimicrobial resistance (AMR) is a global and English public health priority. Despite antibiotic prescribing in England slowly decreasing since 2014, the majority of antibiotics continue to be prescribed in primary care (72% in general practice in 2018), with up to 23% estimated to be prescribed inappropriately, that is for self-limiting respiratory tract infections (RTIs) when antibiotics are not indicated or by using a suboptimal type of antibiotics (eg, broad instead of narrow spectrum). While not all antibiotic prescribing is inappropriate, further optimising antibiotic prescribing behaviours (eg, by reducing

Strengths and limitations of this study

- The study combined systematic reviewing and behavioural analysis methods to assess qualitative and intervention studies. This novel approach allowed us to identify how well existing interventions address influences on antibiotic prescribing and potential improvements.

- We focused on developing recommendations for English primary care so generalisability of findings to other contexts may be limited.

- Behavioural analysis relies on the quality and completeness of available reports and does not account for potential differences in delivery, contexts or engagement with and receipt of interventions.

unnecessary antibiotics for self-limiting infections) in primary care remains important.

Many antimicrobial stewardship (AMS) strategies have targeted healthcare professionals’ (HCPs) behaviours to optimise antibiotic prescribing. For example, an overview of systematic reviews identified 44 trials evaluating interventions targeted at antibiotic prescribing in primary care and found that the average effect size from these interventions tends to be small, with most interventions achieving a quarter or less reduction in total antibiotic prescribing. Recently, 39 nationally implemented interventions (with 22 targeted at prescribers) were identified that aimed at reducing antibiotic prescribing and use for RTIs in England alone. Considering the large number of interventions and the typically modest effects, it would be informative to identify how well the interventions address influences on antibiotic prescribing and whether interventions have ‘gaps’ which could highlight areas for improvement.

Behavioural analysis offers one possible approach to assessing behaviour change interventions. It involves categorising determinants of (influences on) behaviour(s) and intervention components to link them to behavioural mechanisms of action. This can be done by using existing behavioural sciences frameworks that synthesise behaviour change theories and mechanisms. The Theoretical Domains Framework (TDF) is a synthesis of determinants of behaviour from existing behaviour change theories; it includes 14 domains of determinants of behaviour (box 1). The Behaviour Change Wheel (BCW) is a synthesis of behaviour change theories with the COM-B model (capability, opportunity, motivation—behaviour) at the centre, and integrating it with nine intervention functions and seven policy categories (box 1). The third helpful framework is the Behaviour Change Techniques (BCTs) Taxonomy (V.1) that includes 93 types of techniques (‘active ingredients’) to change behaviours. These frameworks allow moving from focusing on specific intervention components to more general, abstract categories so that different types of interventions can be linked with behaviour change mechanisms and compared. For example, an AMS intervention may include the following component: explaining the link between antibiotic prescribing, AMR and future ineffective antibiotic treatment. We can identify a behaviour change mechanism that this component aims to facilitate by expressing it as a BCT ‘providing information about health consequences’ that works through ‘education’ (intervention function) by targeting change in ‘beliefs about consequences’ (TDF domain).

There is a risk that despite numerous AMS interventions, they may overlap in their content and target the same determinants of behaviour (TDF domains) using the same mechanisms (BCTs/intervention functions). Behavioural analysis allows recognising any overlap to help avoid potential duplication and identifying potential gaps: any influences which are not targeted or any BCTs and intervention functions that are underused.

Such behavioural analysis methods have been used, for example, to assess interventions to prevent sepsis, catheter-associated urinary tract infections, AMS interventions targeted at public and national AMS interventions.

Building on a recent study that assessed the behavioural content of national AMS interventions in England, the overall aim of this study was to identify possible ways to optimise AMS interventions in English primary care. To achieve this we aimed to assess the extent to which current national and research interventions addressed influences on antibiotic prescribing (and identify any potential gaps) by addressing the following objectives:
1. Identify the influences on appropriate antibiotic prescribing.
2. Identify research interventions that are effective at reducing antibiotic prescribing.

3. Assess the extent to which national and effective, research-tested AMS interventions address key influences on antibiotic prescribing.

We focused on interventions targeting HCPs’ antibiotic prescribing for RTIs in primary care (including general practices, out-of-hours (OOH), walk-in/urgent care centres and community pharmacies).

**METHODS**

The study was conducted in three stages. First, we conducted a rapid review of qualitative studies to identify perceived key influences on antibiotic prescribing. Second, we conducted a rapid review of intervention studies to identify research evidence on effective AMS interventions. We then compared these research interventions with previously identified national AMS interventions to see which effective interventions have been already nationally implemented. Third, we conducted a behavioural analysis, using behaviour sciences frameworks and matrices, to compare the extent to which national and research AMS interventions address the key influences on antibiotic prescribing.

**Stage 1: Rapid review of qualitative studies to identify influences on antibiotic prescribing**

**Search and study selection**

Five electronic databases (Medline, Embase, PsycINFO, Cochrane Library and Cumulative Index to Nursing and Allied Health Literature (CINAHL)) were searched on 5 November 2018 (updated on 18 June 2020) using a detailed search strategy informed by previous research (online supplemental document 1). Two searches were conducted: one to identify systematic reviews and one for primary qualitative studies.

We included systematic reviews of qualitative studies and primary qualitative studies of HCPs’ self-reported views about antibiotic prescribing for RTIs in relevant settings (ie, general practice, OOH, walk-in/urgent care, community pharmacy). Conference abstracts, dissertations/theses, reviews without eligible studies and not in English were excluded. Due to time constraints and to identify studies most relevant to current practice in England, we included only studies published since January 2000 and conducted in the UK (studies conducted across the UK did not report findings for England alone). To further focus on influences on appropriate prescribing (rather than influences on the use of particular interventions), we excluded papers reporting process evaluations of and focused on specific interventions.

**Data extraction and analysis**

We extracted data on study characteristics, aims and key findings, study design, methods, setting and participants. Included papers were uploaded to NVivo software (V.11). All data within each paper relevant to the research questions were included in the analysis, including authors’ interpretations and direct participants’ quotes. Three papers were independently coded by AJB, MW and ST-C using an inductive approach. After discussion, a coding framework was agreed and then used to code remaining papers. The codes were reviewed, discussed and arranged into higher level categories describing types of influences on antibiotic prescribing. The coded data were reviewed to identify whether each influence was described as a barrier or facilitator to appropriate antibiotic prescribing, or both.

We used the TDF to categorise each barrier and facilitator to enable a comparison between the types of influences reported by HCPs and the types of influences targeted by AMS interventions. TDF domains were ranked based on: frequency (number of studies reporting influences within the domain); elaboration (number of types of influences identified within the domain); and evidence of ‘bi-directionality’ (when influences within the domain could act as either barriers or facilitators). The six highest ranked domains were considered to be the ‘key TDF domains’, following previous research.

**Stage 2: Rapid review of research studies to identify effective AMS interventions**

**Search and study selection**

The same five electronic databases were searched on 5 November 2018 (updated on 25 June 2020) using a search strategy informed by previous research (online supplemental document 2). Two searches were conducted: one to identify systematic reviews and one for primary studies.

We included systematic reviews and primary studies of AMS interventions targeting antibiotic prescribing or use for RTIs in relevant settings (ie, general practice, OOH, walk-in centres, community pharmacy). Any study design...
was included, but papers had to report impact of interventions on changing antibiotic prescribing or use. As above, only studies published in English since January 2000 and conducted in the UK were included.

Titles and abstracts, and then full texts, were screened by AJB, with 20% independently double-screened by MW. Differences were discussed and resolved with ST-C. Individual studies were initially identified from the included systematic reviews. Since the most up-to-date systematic review searched for studies up to January 2018, studies published in 2018 retrieved from our database search were screened to identify more recent studies. All electronic search results were also searched specifically for studies conducted in OOH, walk-in/urgent care centres and community pharmacy.

Data extraction and analysis
We extracted data on study characteristics, aims, study design, interventions and comparators, setting, participants and effectiveness of interventions on antibiotic prescribing/use. The data were summarised descriptively.

The identified research interventions were compared with the nationally implemented AMS interventions in England (identified previously) to see which national interventions were evaluated and had evidence of effectiveness, and which effective research interventions have not been yet nationally implemented.

RESULTS
Influences on antibiotic prescribing
Three relevant systematic reviews and 10 studies (published after the most up-to-date review) were identified, resulting in 65 potentially eligible qualitative studies being screened. After full-text screening, 13 qualitative studies were included, published between 2003 and 2017. Eleven studies were conducted in general practice, one in OOH, and one in a walk-in centre. Eleven studies involved general practitioners and five nurse and/or pharmacist prescribers. The update search in June 2020 identified 105 references, with one study matching the inclusion criteria (although it was not included in the analysis). Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow chart is available in online supplemental document 3 and study characteristics in online supplemental document 4.

Forty-one types of self-reported influences on antibiotic prescribing were identified and organised into 14 categories (table 1). Within these influences, 49 barriers and 45 facilitators to appropriate prescribing were identified. Table 2 reports the six highest ranked TDF domains. There were no self-reported influences categorised with TDF domains ‘optimism’, ‘goals’ and ‘behavioural regulation’.

Effective AMS interventions
Eighteen relevant systematic reviews and 26 individual studies (published after the most up-to-date review) were identified, resulting in 48 potentially eligible studies being screened. After full-text screening, 17 studies were

| 11. Reinforcement             | 2                               | 1                                    | No                | ▶ Attitudes to and use of AMS strategies (use of financial incentives) |

*Number of studies in which the TDF domain was identified. †Number of influences identified in studies in each TDF domain. ‡Bidirectionality was when the influence could be either a barrier or a facilitator to appropriate prescribing (eg, the influence ‘knowledge of evidence or guidelines’ could be a barrier (ie, a lack of knowledge of evidence or guidelines) or a facilitator (ie, having knowledge of evidence and guidelines). §TDF domain ‘intentions’ was double-coded with TDF domains ‘skills’ and ‘beliefs about consequences’. ¶TDF domain ‘emotions’ was double-coded with TDF domain ‘beliefs about consequences’. **Some influences included in the theme ‘Monitoring, auditing, feedback and accountability’ were also double-coded with TDF domain ‘social influences’. ††Some influences included in the theme ‘Awareness & perceptions of responsibility for AMR’ were also double-coded with TDF domain ‘beliefs about consequences’. AMR, antimicrobial resistance; AMS, antimicrobial stewardship.
Comparison of national and research interventions

Twenty-six nationally implemented interventions targeting prescribers and community pharmacists in England were identified in previous research. Four effective research interventions have been nationally implemented (table 3).

Behavioural content of AMS interventions

Table 4 summarises the behavioural content (TDF domains, intervention functions and BCTs) of the 26 national interventions (identified and analysed previously, including the four effective research interventions), and of the five effective research-only interventions (31 in total). The content of each effective research intervention is reported in online supplemental document 7.

TDF domains

Interventions addressed all 14 TDF domains. The majority (81%) of interventions addressed ‘knowledge’, which was not a key influence (based on the ranking of self-reported influences identified in qualitative studies). Four of the six key TDF domains were addressed by several interventions. For example, ‘skills’ (55% of interventions) was addressed by providing training on communication and consultation skills and instructions related to antibiotic prescribing; ‘environmental context and resources’ (48%)—by adding objects (eg, leaflets, clinical scores) to practice environment; ‘beliefs about consequences’ (45%)—by providing information about benefits and harms of antibiotics, and impact on future consultations; ‘social influences’ (36%)—by using trusted credible sources to promote AMS and prudent prescribing, comparing prescribing rates between practices, providing support and encouragement (including peer discussions and sharing). The key domain ‘intentions’ was addressed by seven nationally implemented (23% of all) interventions (eg, by encouraging HCPs’ intentions to review prescribing or make a pledge on the Antibiotic Guardian website), three of which were also effective research-tested interventions (ie, TARGET resources, CMO letters and STAR training). The key domain ‘emotions’ was addressed in only one intervention (ie, the nationally available Health Education England video comparing AMR to a terrorist attack).

Intervention functions

Interventions used eight (out of nine) intervention functions. ‘Training’ was used in 87% of interventions, for example, by providing training, instructions and demonstrations of relevant behaviours. ‘Enablement’ was used in 77% of interventions, for example, by providing support (eg, via meetings or forums to reflect on own practice and share good practice), patient leaflets (used as substitute for prescriptions) and facilitating action planning and monitoring of antibiotic prescribing. ‘Education’ was used in 74% of interventions, for example, by providing information about antibiotic prescribing, prescribing guidelines and AMR. ‘Persuasion’ was used in 12 nationally implemented interventions, three of which were also effective research-tested interventions (ie, TARGET resources, CMO letters and STAR training). ‘Modelling’ was used in three national interventions, two of which were also effective research interventions (ie, TARGET resources and STAR training). ‘Coercion’ was used in two national interventions (ie, via BCT ‘future punishment’ in the UK five-year AMR strategy and ‘managing acute respiratory tract infection’ e-module), but neither were research-tested. ‘Restriction’ was the only intervention function not used in any intervention.

Behaviour change techniques

Thirty-four BCTs were used in interventions; between 1 and 15 (mean 5) in national interventions, and 3–15 (mean 8) BCTs in research interventions. The majority (94%) of interventions included the BCT ‘instruction on how to perform the behaviour’. In research interventions it was delivered, for example, by providing prescribing guidelines and instructions related to consultation skills, use of leaflets, CRP POC testing and use of other resources (eg, TARGET toolkit). BCT ‘information about health consequences’ was used in 55% of interventions, for example, by providing information about links between antibiotic prescribing and AMR or providing evidence about health-related outcomes of using or not using antibiotics for RTIs. Other commonly used BCTs (in over 25% of interventions) were: ‘adding objects to the environment’ (eg, patient leaflets, decision support tools, computer prompts, clinical scores), ‘feedback on behaviour’ (eg, feedback on antibiotic prescribing rates) and ‘credible source’ (eg, CMO or other trusted HCPs to communicate information about antibiotics). Only one BCT ‘verbal persuasion about capabilities’ was used in a

research intervention and not in any national intervention—all other BCTs used in research interventions were also already used in national interventions.

Theoretical congruence with key TDF domains
Based on a predefined matrix, all six key TDF domains (identified on the basis of self-reported influences on antibiotic prescribing) were targeted by at least one congruent intervention function (online supplemental document 8). However, theoretical congruence was lacking between intervention function ‘restriction’ and linked key TDF domains ‘social influences’ and ‘environmental context and resources’ as the function was not used in any intervention.

Interventions contained most theoretically congruent BCTs within the TDF domains ‘environmental context and resources’ (67% of theoretically congruent BCTs), ‘beliefs about consequences’ (60%) and ‘social influences’ (60%) (table 5). There was a low proportion of potential, theoretically congruent BCTs used in the domain ‘skills’ (24%), with most interventions using one BCT instruction on how to perform the behaviour’. No theoretically congruent BCTs addressed the domain ‘emotions’. Of the 34 BCTs identified in interventions, 16 BCTs had high and 14 medium theoretical congruence with key TDF domains, whereas 4 BCTs (‘behavioural substitution’, ‘focus on past success’, ‘problem solving’ and ‘verbal persuasion about capabilities’) had low congruence, meaning they were not linked with theoretically congruent key TDF domains (online supplemental document 9).

**DISCUSSION**
We identified 41 types of self-reported influences on antibiotic prescribing and six key TDF domains representing these influences. We next identified nine research-tested interventions effective at reducing antibiotic prescribing, with four already nationally implemented. All research interventions contained multiple behavioural components. Lastly, we compared the behavioural content of 31 (national and effective research) interventions with the six key TDF domains of influences. This behavioural analysis showed that interventions address all 14 TDF domains, 8/9 intervention functions and 34 BCTs (with 30 theoretically congruent with the key TDF domains). All BCTs except ‘verbal persuasion about capabilities’ used in effective research interventions were also used in national interventions. Interventions used most (50%–67%) theoretically congruent BCTs within the TDF domains ‘environmental context and resources’, ‘beliefs about consequences’ and ‘social influences’.

**Implications**
We found that five effective research interventions have not been implemented nationally in England, with three
### Table 5  Frequency of theoretically congruent behaviour change techniques (BCTs) within the key Theoretical Domains Framework (TDF) domains

| BCTs theoretically congruent with the key TDF domains (based on a predefined matrix) | BCT frequency | % Potentially relevant BCTs used |
| --- | --- | --- |
| **TDF domain 1: beliefs about consequences** | | |
| Information about health consequences | 14 | 3 | 60% (9/15) |
| Information about social and environmental consequences | 5 | 2 |
| Salience of consequences | 2 | 0 |

of them also supported by international evidence from systematic reviews. Thus, wider implementation of these interventions may be route to improvement. These interventions include:

- Electronic decision support tools (accessed during consultations), which are also supported by international evidence from systematic reviews. The update search identified another study that evaluated a multifaceted intervention of electronically delivered prescribing feedback and decision support and showed safe and moderate reductions of antimicrobial prescribing for adults with RTIs in UK general practices.

- Training in the interactive use of ‘When Should I Worry’ booklets for parents/carers of children with RTIs; the use of written information is supported by systematic reviews.

- CRP POCT (with and without communication skills training and interactive use of a patient booklets), which is supported by evidence from systematic reviews; however, national implementation would need to consider specific barriers to adoption and longer-term sustainability. The update search identified a 12-month follow-up of the included intervention, and showed that the initial improvement in antibiotic prescribing when using CRP POCT decreased, while the initially lesser effects of communication skills training were more sustainable.

- Implementing evidence-based practice protocols for management of RTIs (although the evidence is from a pre–post study in one general practice).

- Workshops on antibiotic prescribing guidelines and promoting of online TARGET resources; these are currently being rolled out more widely through training of TARGET trainers.

While these interventions have not been nationally implemented in England, some (eg, CRP POCT) may have been implemented locally, depending on local priorities and resources. Some interventions (eg, developing and implementing specific practice-based protocols) may be more suited for local, tailored implementation. As antibiotic prescribing varies, specific, tailored interventions may be needed locally (and not necessarily nationally) to address particular issues in areas/practices with high prescribing. Implementation of interventions may also need to be tested locally before a national roll-out.

The behavioural analysis showed that current AMS interventions include a wide range of TDF domains, intervention functions and BCTs. However, the key TDF domains that are currently under-represented in AMS interventions could be addressed by a wider range of theoretically congruent BCTs; for example:

- The top TDF domain ‘beliefs about consequences’ is currently mainly addressed by BCT ‘information about health consequences’; other congruent BCTs could be used, such as ‘information about emotional consequences’ (eg, resulting from providing good
care and educating patients by prescribing only when necessary) or ‘comparative imagining of future outcomes’.

- Key TDF domain ‘skills’ is primarily addressed by BCT ‘providing instructions’; other BCTs could also be used, for example, ‘reversing and forming habits’.
- Key TDF domain ‘intentions’ could be addressed in more interventions by theoretically congruent BCTs, for example, ‘commitment’ or ‘behavioural contract’.
- Key TDF domain ‘emotions’ is currently not addressed by theoretically congruent BCTs; interventions could include BCTs, such as ‘reducing negative emotions’ (eg, those related to not prescribing or concerns with medico-legal consequences) or ‘social support (emotional)’ (eg, providing encouragement or reassurance).

- Intervention function ‘restriction’ is currently not addressed in interventions, despite being congruent with the key TDF domains ‘social influences’ and ‘environmental context and resources’; it could be addressed, for example, by making access to antibiotics more restricted than to alternative strategies for managing self-limiting illness (eg, leaflets) or adding barriers to immediate use of antibiotics (eg, using delayed/back-up prescriptions by post-dating or asking patients to collect them at a later date if needed).

Current, or new, interventions could also facilitate under-used behavioural mechanisms (ie, TDF domains and BCTs that are less commonly addressed/used); for example:

- TDF domain ‘social/professional role and identity’ could be facilitated, for example, by BCTs providing emotional ‘social support’ (eg, encourage perceiving self-care advice and patient education as central to HCPs’ roles and address concerns perceived as undermining professional roles/expertise).
- TDF domain ‘beliefs about capabilities’, for example, by BCTs ‘verbal persuasion about capabilities’ (used in research but not in national interventions), ‘focus on past success’ or ‘problem solving’.
- TDF domain ‘memory, attention, decision making’, for example, by BCTs ‘prompts and cues’ (eg, prompting self-care advice or delayed prescription instead of immediate antibiotics).
- TDF domain ‘reinforcement’, for example, by BCTs (material and non-material) ‘incentives’ or ‘rewards’.

These suggestions should be considered carefully as there is currently no evidence on whether addressing more or fewer, and which, TDF domains, intervention functions and BCTs contribute to effectiveness of AMS interventions. Future research may test effectiveness of specific mechanisms and BCTs in changing behaviours related to AMS. Qualitative research suggests that multifaceted interventions (ie, combining multiple interventions within one approach) may be more attractive and helpful to clinicians, especially with components that help reflect on own prescribing, decrease clinical uncertainty, educate about appropriate prescribing and promote patient-centred care. Such multifaceted interventions may provide better results, but more primary research evidence is needed.

In addition to optimising the content of AMS interventions, it is important to increase engagement with these interventions. Consulting relevant stakeholders may help identify factors specific to implementation and engagement. For example, high workloads, competing priorities and insufficient time were reported by HCPs as barriers to appropriate antibiotic prescribing, and by stakeholders as barriers to engaging with current AMS interventions in England. Thus, specifically targeting such barriers may improve both engagement and prescribing. More in-depth analysis focused on specific interventions (eg, involving both behavioural analysis and consultations with intervention users) may help identify implementation-specific opportunities for optimisation.

It may also be informative to explore why interventions may be less or not effective. In our behavioural analysis of intervention content, we did not include interventions that were not shown effective (ie, with statistically significant reduction of antibiotic prescribing). However, most showed promising results. Two studies were small service evaluations of diagnostic testing without pre-post measures or comparators, but showing that a minority of patients tested required antibiotics.

One multifaceted intervention (web-based tool and printouts for carers) for children with RTIs showed higher rates of antibiotic prescribing in the intervention than control arm, but the authors considered this to be due to a differential recruitment (with more children with severe illness in the intervention arm). Despite sometimes non-significant differences between trial arms testing delayed prescriptions (particularly those comparing different formats), studies showed that delayed prescriptions can safely reduce patients’ use of antibiotics. Further behaviour change interventions are also needed aimed at promoting prescribers’ choice to use delayed prescriptions.

Finally, we found that the majority of the UK-based qualitative and intervention studies have been conducted in general practice. Only one identified intervention study was conducted in urgent care/walk-in centre, evaluating CRP POCT and showing promising results. In community pharmacy, a sore throat test-and-treat service (using the Centor criteria and a throat swab) showed that only 9.8% patients tested were given antibiotics. The update search identified two recent studies in community pharmacies. One pilot study showed that the majority of tested patients were recommended to ‘watch and wait’ or self-care, rather than antibiotics. The other evaluated a multifaceted intervention including AMS webinar and patient leaflets, and showed more frequent self-care advice and fewer referrals to general practice in the intervention arm. Future research should focus more on understanding influences on antibiotic prescribing/use, and developing, testing and optimising...
AMS interventions in primary care settings other than general practice.

**Strengths and limitations**

By using systematic methods for identifying and reviewing relevant literature, including evidence on effectiveness of interventions, we have extended the previous research on AMS interventions implemented in English primary care. The study combined systematic reviewing with behavioural analysis methods, using a novel approach and established theoretical frameworks. These were also supplemented by feedback from stakeholders and experts, reported previously.

As up-to-date evidence from systematic reviews is available, we used rapid review methods (eg, studies’ quality was not assessed). We aimed to develop suggestions for AMS interventions in England so we only included UK-based studies. The majority of studies identified were conducted in general practice. Thus, generalisability of findings and implications for other settings are limited. Influences on prescribing were identified only from qualitative studies of self-reports—it is possible that some influences on antibiotic prescribing were missed (eg, subconscious) or some were over-reported (eg, those most salient to participants). Conducting and reviewing other types of studies (eg, analyses of actual prescribing, predictors of prescribing or patients’ perspectives) might lead to different influences being identified and ranked. We used prespecified criteria to identify the key domains of influences—other domains of influences might also be important to address. Coding behavioural content of interventions depended (and was limited by) the reporting quality and did not account for differences in delivery, contexts or engagement with and receipt of interventions or BCTs. The relevance, importance and effectiveness of different BCTs or intervention functions may vary between types of interventions, behaviours and contexts. Links between constructs may also evolve as the frameworks, definitions and matrices develop. Finally, we used the behavioural analysis tools retrospectively to assess the content of interventions that (except) were not developed or reported using these frameworks (many published before the frameworks), so the coding relied on our interpretation of intervention components in behavioural terms. Such retrospective use of behavioural frameworks is common but it will be more precise and reliable as more researchers use these tools/frameworks to develop and describe behavioural interventions.

**CONCLUSIONS**

National and effective research AMS interventions in England address a relatively wide range of TDF domains, intervention functions and BCTs, and target the key types of influences on antibiotic prescribing. AMS in England may be further optimised by nationally implementing other effective interventions (eg, electronic decision support tools, training in interactive use of leaflets, point-of-care CRP testing) and by using additional theoretically congruent BCTs to target the less commonly addressed influences (eg, BCTs reversing and forming habits, reducing negative emotions or providing social support). Where appropriate, effective AMS interventions could also be adapted to, tested and implemented in other primary care settings (ie, OOH, urgent care, community pharmacies) where little research has been conducted.
