MINIMUM AREA ISOSCELES CONTAINERS

GERGELY KISS, JÁNOS PACH, GÁBOR SOMLAI

ABSTRACT. We show that every minimum area isosceles triangle containing a given triangle \(T\) shares a side and an angle with \(T\). This proves a conjecture of Nandakumar motivated by a computational problem. We use our result to deduce that for every triangle \(T\), (1) there are at most 3 minimum area isosceles triangles that contain \(T\), and (2) there exists an isosceles triangle containing \(T\) whose area is smaller than \(\sqrt{2}\) times the area of \(T\). Both bounds are best possible.

1. INTRODUCTION

Given two convex bodies, \(T'\) and \(T\), in the plane, it is not easy to decide whether there is a rigid motion that takes \(T'\) into a position where it covers \(T\). Suppose, for instance, that we place a 2-dimensional convex body \(T'\) in the 3-dimensional space, and let \(T\) denote the orthogonal projection of \(T'\) onto the \(x\)-\(y\) plane. The area of \(T'\) is at least as large as the area of \(T\), and it looks plausible that \(T'\) can be moved to cover \(T\). However, the proof of this fact is far from straightforward; see [3, 12]. As Steinhaus [21] pointed out, it is not even clear how to decide, whether a given triangle \(T'\) can be brought into a position where it covers a fixed triangle \(T\). The first such algorithm was found by Post in 1993, and it was based on the following lemma.

**Lemma 1.1 (Post).** If a triangle \(T'\) can be moved to a position where it covers another triangle \(T\), then one can also find a covering position of \(T'\) with a side that contains one side of \(T\).

In many problems, the body \(T'\) is not fixed, but can be chosen from a family of possible “containers,” and we want to find a container which is in some sense optimal. To find a minimum area or minimum perimeter triangle, rectangle, convex \(k\)-gon, or ellipse (Löwner-John ellipse) enclosing a given set of points are classical problems in geometry with interesting applications in packing and covering, approximation, convexity, computational geometry, robotics, and elsewhere [1, 2, 4, 5, 6, 8, 9, 10, 16, 18, 19]. Finding optimal circumscribing and inscribed simplices, ellipsoids, polytopes with a fixed number of sides or vertices, etc., are fundamental questions in optimization, functional analysis, and number theory; see e.g. [7, 13, 11, 20, 22].

Motivated by a computational problem, R. Nandakumar [15] raised the following interesting special instance of the above question: Determine the minimum area of an isosceles triangle containing a given triangle \(T\). The aim of the present note is to solve this problem and to find all triangles for which the minimum is attained. We call these triangles minimum area isosceles containers for \(T\). It is easy to verify that every triangle has at least one minimum area isosceles container (see Corollary [3.1]). However, we will see that in some cases the minimum area isosceles container is not unique.

Our main objective is to prove the following statement conjectured by Nandakumar [15].

**Theorem 1.2.** Let \(T\) be a triangle and let \(T' \supseteq T\) be one of its minimum area isosceles containers. Then, \(T'\) and \(T\) have a side in common, and their angles at one of the endpoints of this side are equal.

For any two points, \(A\) and \(B\), let \(AB\) denote the closed segment connecting them, and let \(|AB|\) stand for the length of \(AB\). To unify the presentation, in the sequel we fix a triangle \(T\) with vertices \(A, B, C\), and side lengths \(a = |BC|, b = |AC|, c = |AB|\). If two sides are of the same length, then \(T\) is the unique minimum area isosceles container of itself, so there is nothing to prove. Therefore, from now on we assume without loss of generality that \(a < b < c\).

To establish Theorem [1.2] and to formulate our further results, we need to introduce some special isosceles triangles associated with the triangle \(ABC\), each of which shares a side and an angle with \(ABC\).

**Special containers of the first kind.** Let \(B'\) denote the point on the ray \(CB\), for which \(|B'C| = |AC| = b\) (see Fig. 1). Analogously, let \(C'\) (and \(C''\)) denote the points on \(AC\) (resp., \(BC\)) such that \(|AC'| = c\) (resp., \(|BC''| = c\)). Obviously, the triangles \(AB'C, ABC',\) and \(ABC''\) are isosceles. We call them special containers of the first kind associated with \(ABC\).
Special containers of the first kind. Let $B_1$ denote the point on the ray $\overrightarrow{AB}$, different from $A$, for which $|B_1C| = |AC| = b$ (see Figure 2). Analogously, let $C_1$ (resp., $C_2$) denote the point on $\overrightarrow{AC}$ (resp., $\overrightarrow{BC}$) for which $|BC_1| = |AB| = c$ and $C_1 \neq A$ (resp., $|AC_2| = |AB| = c$ and $C_2 \neq B$). The triangles $AB_1C$, $ABC_1$, and $ABC_2$ are called the special containers of the second kind associated with $ABC$.

Special containers of the second kind. Let $B_1$ denote the point on the ray $\overrightarrow{AB}$, different from $A$, for which $|B_1C| = |AC| = b$ (see Figure 2). Analogously, let $C_1$ (resp., $C_2$) denote the point on $\overrightarrow{AC}$ (resp., $\overrightarrow{BC}$) for which $|BC_1| = |AB| = c$ and $C_1 \neq A$ (resp., $|AC_2| = |AB| = c$ and $C_2 \neq B$). The triangles $AB_1C$, $ABC_1$, and $ABC_2$ are called the special containers of the second kind associated with $ABC$.

Special containers of the third kind. Let $\overline{A}$ be the intersection of the perpendicular bisector of $BC$ and the line $AC$. Since we have $b = |AC| < |AB| = c$, the point $\overline{A}$ lies outside of $ABC$. Analogously, denote by $\overline{B}$ (resp., $\overline{C}$) the intersection of the perpendicular bisector of $AC$ (resp. $AB$) and the line $BC$. Note that $\overline{ABC}$ and $\overline{AB}C$ do not contain $ABC$ if $\angle BCA \geq 90^\circ$. The triangles $\overline{ABC}$, $\overline{ABC}$, and $\overline{ABC}$ are called special containers of the third kind associated with $ABC$, provided that they contain $ABC$. Thus, if $ABC$ is acute, then it has three special containers of the third kind. Otherwise, it has only one (see Figure 3).

All special containers share a common angle and a common side with the original triangle $ABC$. Obviously, there is no other isosceles container having the same property. Indeed, for each vertex of $ABC$, there are at most 3 isosceles triangles that share this vertex and the angle at this vertex with $ABC$, and also have a common side with $ABC$.

Therefore, Theorem 1.2 is an immediate corollary of the following statement.

**Theorem 1.3.** All minimum area isosceles containers for a triangle are special containers of the first kind, or of the second kind, or of the third kind.

Whenever a minimum area isosceles container of a triangle is acute, we can be more specific.

**Theorem 1.4.** If a minimum area isosceles container of a triangle is acute, then it is a special container of the first kind.

One is tempted to believe that if a triangle is acute, then all of its minimum area isosceles containers are acute and, hence, all of them are special containers of the first kind. However, this is not the case: Example 5.1 demonstrates that there are acute triangles with obtuse minimum area isosceles...
Corollary 1.5. A minimum area isosceles container for an acute triangle is obtuse if and only if it is a special container of the second kind.

It follows from Theorem 1.3 that every triangle has at most 9 minimum area isosceles containers: at most 3 special containers of each kind. In the next section, we prove that there are no minimum area isosceles triangles of the third kind (see Lemma 2.2). Thus, every triangle can have at most 6 minimum area isosceles triangles. In fact, this bound can be further reduced to 3.

Theorem 1.6. Every non-isosceles triangle $ABC$ has at most 3 minimum area isosceles containers, $AB'C$, $ABC'$, and $AB_1C$. In particular, every minimum area isosceles container is a special container of the first or the second kind.

There is a unique triangle $T^*$, up to similarity, which has precisely 3 different minimum area isosceles containers. Its angles are $\alpha^* \approx 41.831452^\circ$, $2\alpha^*$, and $180^\circ - 3\alpha^*$.

Finally, we discuss how large the area of a minimum area isosceles container for a triangle $T$ can be relative to the area of $T$. We also consider the same question for special containers of the first kind.

Theorem 1.7. (a) Every triangle of area $1$ has an isosceles container whose area is smaller than $\sqrt{2}$. (b) Every triangle of area $1$ has a special container of the first kind, whose area is smaller $1 + \frac{\sqrt{5}}{2}$.

Both bounds are best possible.

As (b) is best possible, there exists a triangle of area $1$ whose every special container of the first kind has area larger than $\sqrt{2}$. Therefore, by (a), none of its special containers of the first kind can be a minimum area isosceles container. This disproves an earlier conjecture of Nandakumar, according to which every triangle $T$ admits a minimum area isosceles container which is a special container of the first kind.

Our paper is organized as follows. In Section 2, we prove some useful inequalities for the areas of special containers. In particular, we prove Theorem 1.7 (b). In Section 3 we establish some elementary properties of minimum area isosceles containers. Section 4 contains the proofs of Theorems 1.3 and 1.4. Finally, Theorem 1.6, and 1.7 (a) are proved in Section 5.

2. Preliminaries—Proof of Theorem 1.7 (b)

In this section, we collect some basic facts about special containers and establish Theorem 1.7 (b).

First, we consider special containers of the first kind, because their areas can be easily compared to the area of the triangle $ABC$. As everywhere else, we assume that the side lengths of $ABC$ satisfy $a < b < c$. The area of $ABC$ is denoted by $t(ABC)$.

Lemma 2.1. For any non-isosceles triangle $ABC$, we have

(a) $t(ABC'''') > t(ABC')$, 
(b) $t(ABC') > t(ABC''')$ (resp., $t(AB'C) \geq t(ABC''')$) if and only if $b^2 > ac$ (resp., $b^2 \geq ac$).
**Proof.** Let $m$ be the length of the altitude of $ABC$ perpendicular to the side $BC$. We have $t(ABC) = \frac{a \cdot m}{2}$ and $t(AB'C) = \frac{b \cdot m}{2}$. Thus, the ratio $t(AB'C)/t(ABC) = b/a$.

Similar arguments show that

$$\frac{t(ABC')}{t(ABC)} = \frac{c}{b} \quad \text{and} \quad \frac{t(ABC'')}{t(ABC)} = \frac{c}{a}.$$  

(a) Since $b > a$, we have $t(ABC'') > t(ABC')$.

(b) Straightforward.

Next, using Lemma 2.1 we determine the supremum of the ratio of the area of the smallest isosceles containers of the first kind to the area of the original triangle $ABC$. This will also provide an upper bound for the ratio of the area of a smallest area isosceles containers to the area of the original triangle. This fact will be frequently used in the sequel.

**Proof of Theorem 1.7 (b).** Let $r_1^*$ denote the supremum of the ratio of the area of a smallest container of the first kind associated with $ABC$ and the area of $ABC$, over all triangles $ABC$ with the above property. We show that $r_1^* = \frac{1 + \sqrt{5}}{2}$. Suppose without loss of generality that $a = 1$. By our assumptions and the triangle inequality, we have $1 < b < c < b + 1$. Let

$$r(b, c) := \begin{cases} b & \text{if } b^2 \leq a, \\ c/b & \text{if } b^2 > c. \end{cases}$$

By Lemma 2.1, $r(b, c) = \min \left( \frac{t(AB'C)}{t(ABC)}, \frac{t(ABC'')}{t(ABC)} \right)$, and

$$r_1^* = \sup_{1 < b < c < b + 1} r(b, c).$$

If $b^2 \leq c < b + 1$, then $r(b, c) = b < \frac{1 + \sqrt{5}}{2}$.

If $b^2 > c$ and $b < \frac{1 + \sqrt{5}}{2}$, then $r(b, c) = \frac{c}{b} < b < \frac{1 + \sqrt{5}}{2}$. Otherwise, if $b \geq \frac{1 + \sqrt{5}}{2}$ (and, hence, $b^2 > c$), then $r(b, c) = \frac{c}{b} < \frac{b + 1}{b} = 1 + \frac{1}{b} < 1 + \frac{2}{1 + \sqrt{5}} = \frac{1 + \sqrt{5}}{2}$. Thus, we obtain that $r_1^* \leq \frac{1 + \sqrt{5}}{2}$.

The supremum of $r(b, c)$, restricted to the parabola arc $c = b^2 < b + 1$ in the $(b, c)$ plane, is $\frac{1 + \sqrt{5}}{2}$. Since every point $(b, c)$ of this arc corresponds to a triangle with side lengths $1, b, c$, we obtain that $r_1^* = \frac{1 + \sqrt{5}}{2}$, as required.

We show that for any special container of the third kind, there exists a special container of the second kind whose area is smaller area.

**Lemma 2.2.** For any triangle $ABC$, we have

$$t(AB_1C) < t(AB\overline{C}), \quad t(ABC_1) < t(A\overline{BC}), \quad \text{and} \quad t(ABC_2) < t(\overline{ABC}).$$

Thus, the area of a special container of the third kind can never be minimal.

**Proof.** We verify only the first inequality; the other two statements can be shown analogously.

Assign planar coordinates to the points. We can assume without loss of generality that $A = (0, 0)$, $B = (2, 0)$, $C = (p, q)$, and $\overline{C} = (1, d)$. Then $t(AB\overline{C}) = d$. The equation of the line passing through $B$, $C$, and $\overline{C}$ is $dx + y = 2d$. Taking $p = 1 + s$ for some $0 < s < 1$, we have $q = d(1 - s)$ and $B_1 = (2(1 + s), 0)$. Hence, $t(AB_1C) = d(1 - s^2) < d = t(AB\overline{C})$.  

![Figure 4. Proof of Lemma 2.2](image-url)
3. Three useful lemmas

The aim of this section is to prepare the ground for the proofs of the main results that will be given in the next two sections.

First, we show that the problem is well-defined, that is, for every triangle $ABC$, there is at least one isosceles triangle containing $ABC$, whose area is smaller than or equal to the area of any other isosceles container.

Corollary 3.1. Every triangle $ABC$ has at least one minimum area isosceles container.

Proof. It follows from Theorem 1.7 (b) that the area of a minimum area isosceles container is at most $\frac{1+\sqrt{5}}{2}$ times larger than the area of the original triangle $ABC$. Therefore, the vertices of any minimum area isosceles container must lie within a bounded distance from $ABC$, and the statement follows by a standard compactness argument. □

Lemma 3.2. Let $ABC$ be a triangle and $SPR$ a minimum area isosceles container for $ABC$. Then, $A, B, C$ are on the boundary of $SPR$. Moreover, $ABC$ and $SPR$ have a common vertex.

Proof. The first part of the statement follows from Lemma 1.1 and the minimality of $SPR$. Either one of the endpoints of the common segment of the sides of $ABC$ and $SPR$ is a vertex, or, by the minimality of $SPR$, their vertices opposite to this segment coincide. □

Let $SPR$ be an isosceles triangle and let $m_S, m_P, m_R$ denote the midpoints of the sides $PR, SR,$ and $SP$, respectively. The boundary of $SPR$ splits into three polygonal pieces, $\overline{m_Pm_R}, \overline{m_Rm_S}$ and $\overline{m_Sm_P}$, each of which consists of two closed line segments. Namely,

\[
\overline{m_Pm_R} = m_P S \cup Sm_R, \quad \overline{m_Rm_S} = m_R P \cup Pm_S, \quad \overline{m_Sm_P} = m_S R \cup Rm_P.
\]

See Figure 5.

Lemma 3.3. Let $ABC$ be a triangle and $SPR$ a minimum area isosceles container for $ABC$. Then, each of the closed polygonal pieces $\overline{m_Pm_R}, \overline{m_Rm_S}$ and $\overline{m_Sm_P}$ contains precisely one vertex of $ABC$.

Proof. By Lemma 3.2, the vertices $A, B, C$ lie on the boundary of $SPR$. Suppose for contradiction that the closed polygonal piece $\overline{m_Pm_S}$ contains two vertices of $ABC$. We may and do assume without loss of generality that these vertices are $B$ and $C$.

Let $T_1$ and $T_2$ denote the intersection points of the segment $m_Pm_S$ with $AB$ and $AC$, respectively. The quadrangle $CBT_1T_2 \subseteq Rm_Pm_S$, so that $t(CBT_1T_2) \leq t(Rm_Pm_S)$. Since $|T_1T_2| \leq |m_Pm_S|$, we have $t(AT_1T_2) \leq t(m_Sm_Pm_R)$. Consequently, we get

\[
t(ABC) \leq t(Rm_Pm_S) + t(m_Sm_Pm_R) = \frac{1}{2}t(SPR).
\]

Equality holds if and only if $A = S, B = R, C = m_S$ or $A = P, B = R, C = m_P$.

On the other hand, by Theorem 1.7 (b), we obtain $t(SPR) < \frac{1 + \sqrt{5}}{2}t(ABC)$, the desired contradiction. □

![Figure 5. Illustration for the proof of lemma 3.3.](image-url)
4. NANDAKUMAR’S CONJECTURE—PROOFS OF THEOREMS 1.3 AND 1.4

We start with the proof of Theorem 1.3, which immediately implies Nandakumar’s conjecture (Theorem 1.2).

**Proof of Theorem 1.3** Let $SPR$ be a minimum area container for $ABC$ with apex $R$. By Lemma 3.2, $A$, $B$, and $C$ are on the boundary of $SPR$, and the triangles $SPR$ and $ABC$ share a vertex. Using Lemma 3.3 under the assumption that $ABC \neq SPR$, we can distinguish 8 cases, up to symmetry (see Figure 6). Cases (1)-(3) represent those instances when $ABC$ and $SPR$ have two common vertices. In these cases, $SPR$ is a special container of the first, the second, and the third kind, respectively, so we are done.

In the remaining cases, $ABC$ and $SPR$ have only one vertex in common. In cases (4)-(6), this vertex is a base vertex (say, $S$) of $SPR$. Finally, in cases (7)-(8), $R$ is the unique common vertex of $ABC$ and $SPR$. It is sufficient to show that in cases (4)-(8), the area of $SPR$ is not minimal.

![Figure 6](image-url)

**Figure 6.** The 8 cases up to symmetry. Triangle $ABC$ is shaded.

First, we discuss cases (5)-(8). Case (4) is more delicate and is left to the end of the proof.

Cases (5) and (6) are analogous. Let $D$ denote the vertex of $ABC$ lying on $RP$. In both cases, we have $ABC \subseteq SPD$. Clearly, $SPR$ is a special container of the third kind associated with $SPD$ and,
by Lemma 2.2, it cannot be minimal. Since every container for $SPD$ is also a container for $ABC$, we conclude that $SPR$ is not a minimum area container for $ABC$.

In case (7), we can find an isosceles triangle with apex $R$ which contains $ABC$ and whose base is properly contained in $PS$. Thus, $SPR$ was not minimal.

In case (8), one vertex of $ABC$ is $R$, another (denoted by $D$) belongs to $Sm_S$, and the third lies on $Ps_S$. Since $SPR$ is an isosceles triangle, we have $\angle RDS \geq 90^\circ$. Hence, $ABC$ can be slightly rotated about $R$ so that it remains within $SPR$, which leads to a contradiction.

It remains to handle case (4). We distinguish two subcases. Denote the apex angle $\angle SRP$ by $\delta$. If $\delta \geq 60^\circ$, then we can rotate $ABC$ about $S$. Indeed, vertex $D$ of $ABC$ belongs to $m_S P$, while the base of the altitude belonging to $PR$ lies on $m_S R$. Hence, we have $\angle DSP \geq 90^\circ$, and the image of $ABC$ through a small counterclockwise rotation about $S$ is still contained in $SPR$. Therefore, in this case, $SPR$ cannot be minimal either.

Therefore, from now on we assume $\delta < 60^\circ$. Choose a suitable coordinate system, in which the vertices of $ABC$ are $(0, 0), (s, 0)$, and $D = (p, q)$. We also have $S = (0, 0)$ and $R = (s + x, 0)$ for some $x > 0$. Since $\delta < 60^\circ < 90^\circ$, vertex $D$ is to the left of $R$, that is, $p < s + x$.

![Figure 7. Possible realizations of Case (4) when $\delta < 60^\circ$.](image)

By simple calculation,

$$P = (s + x, 0) + \frac{(s + x)}{\sqrt{(p - (s + x))^2 + q^2}}(p - (s + x), q).$$

Denote by $m$ the length of the altitude of $SPR$ belonging to the side $SR$. Then, $m$ is equal to the second coordinate of $P$ (see Figure 7). We have

$$m = \frac{q(s + x)}{\sqrt{(p - (s + x))^2 + q^2}}.$$

Let us compute the derivative of the function

$$f(x) = 2t(SPR) = q(s + x)^2 \cdot [(p - (s + x))^2 + q^2]^{-\frac{1}{2}}.$$

We obtain

$$f'(x) = q \left(2(s + x) \cdot \left((p - (s + x))^2 + q^2\right)^{-\frac{1}{2}} + q(s + x)^2(p - (s + x)) \cdot \left((p - (s + x))^2 + q^2\right)^{-\frac{3}{2}}\right) =$$

$$= q(s + x) \cdot \left((p - (s + x))^2 + q^2\right)^{-\frac{3}{2}} \left((p - (s + x))(2p - (s + x)) + 2q^2\right) =$$

$$= q(s + x) \cdot \left((p - (s + x))^2 + q^2\right)^{-\frac{3}{2}} \left[\left(\frac{3}{2}p - (s + x)\right)^2 - \frac{1}{4}p^2 + 2q^2\right].$$

**Case (4/a1):** $q \geq \frac{1}{2}p$. Then, $-\frac{1}{2}p^2 + 2q^2 > 0$ and, hence, $f'(x) > 0$ for all $x \geq 0$. Thus, $f$ is strictly increasing and since $x$ cannot be negative, $f$ takes its minimum at $x = 0$. This means that the area of a special container of the first kind where $x = 0$ (see the triangle with dashed sides on Figure 7(4/a)) is smaller than the area than $SPR$ for $x > 0$.

**Case (4/a2):** $2p < s + x$. Then $\frac{3}{2}p < (s + x) - \frac{3}{2}p$, so that $(\frac{3}{2}p - (s + x))^2 - (\frac{1}{2}p)^2 > 0$. Again, we have $f'(x) > 0$ for all $x \geq 0$ and, as above, we obtain a special container of the first kind whose area is smaller than the area of $SPR$ (see Figure 7(4/a)).

**Case (4/b):** $q < \frac{1}{2}p$ and $2p \geq s + x$. Let $\Delta$ denote the triangle with vertices $(0, 0), (p, q)$, and $(2p, 0)$. It follows from the inequality $2p \geq s + x$ that $\Delta$ is an isosceles container of the second kind associated
with \(ABC\) (see Figure 4(b)). We show that \(\Delta\) has smaller area than \(SPR\). To prove this, we have to verify that
\[
t(\Delta) = pq < q \frac{(s+x)^2}{2\sqrt{(p-(s+x))^2 + q^2}} = t(SPR).
\]
Using our assumption that \((p, q) \in m_S P\), we obtain
\[
p \leq s + x + \frac{(s+x)(p-(s+x))}{2\sqrt{(p-(s+x))^2 + q^2}}.
\]
The right-hand side of the last inequality is the first coordinate of the midpoint \(m_S\) of \(PR\), where \(P\) is given by formula (1) and \(R = (s + x, 0)\). Thus, it is sufficient to show that
\[
(s + x) + \frac{(s+x)(p-(s+x))}{2\sqrt{(p-(s+x))^2 + q^2}} < \frac{(s + x)^2}{2\sqrt{(p-(s+x))^2 + q^2}},
\]
which reduces to \(3p^2 + 4q^2 < 4(s+x)p\). The last inequality holds, because \(p < s + x\) and, by our assumption, \(2q \leq p\). This completes the proof of Theorem 1.3. \(\square\)

**Proof of Theorem 1.4.** By Theorem 1.3 every minimum area isosceles container for a triangle \(ABC\) is one of its special containers. By Lemma 2.2, it must be a special container of the first or the second kind.

Suppose for a contradiction that a minimum area special container \(SPR\) associated with the triangle \(ABC\) is acute, but it is of the second kind. Assume without loss of generality that \(S = B\) and \(R = A\). (The other cases can be treated in a similar manner.) By our notation, \(P = C_2\). We prove that \(t(ABC') < t(ABC_2) = t(SPR)\) (see Figure 8).

![Figure 8](image)

**Figure 8.** An acute minimum area isosceles container cannot be a special container of the second kind.

Indeed, we have \(|AB| = |AC_2| = |AC'|\) and \(<C'AB < <C_2AB\). Since \(SPR = ABC_2\) is acute, it follows that \(t(ABC') < t(ABC_2)\). \(\square\)

**Corollary 4.1.** If a minimum area isosceles container for \(ABC\) is a special container of the second kind, then it must be \(AB_1C\).

**Proof.** By Theorem 1.3 if a special container of the second kind has minimum area, then it has to be non-acute. If \(ABC_2\) is non-acute, then \(ABC_1\) is obtuse and \(t(ABC_2) > t(ABC_1)\), because \(|AB| = |AC_2| = |AC_1|\) and \(<ABC_1 > <ABC_2 \geq 90^\circ\). On the other hand, as \(AB_1C\) and \(ABC_1\) share a base angle at \(A\) and \(b < c\), it follows that \(t(ABC_1) > t(AB_1C)\). \(\square\)

5. Quantitative results—Proofs of Theorems 1.6 and 1.7 (a)

**Proof of Theorem 1.6.** By Theorem 1.3 a minimal area isosceles container for \(ABC\) is a special container associated with \(ABC\). In view of Lemma 2.2, it must be a special container of the first or second kind. By Lemma 2.1 (a) and Corollary 4.1 among special containers of the first kind, it is enough to consider \(ABC'\) and \(AB'C\), and among special containers of the second kind, only \(AB_1C\). These immediately show that every triangle \(ABC\) admits at most 3 minimum area isosceles containers.

If \(ABC\) is an obtuse or right triangle, then \(t(AB'C) > t(AB_1C)\). Indeed, in this case \(|AC| = |AB'\) = \(|AB_1|\), both \(AB'C\) and \(AB_1C\) are obtuse triangles, and their apex angles satisfy \(<ACB' < <ACB_1\). Thus, there are only two candidates for a minimum area isosceles container: \(ABC'\) and \(AB_1C\).
If \( ABC \) is an acute triangle and it has 3 minimum area isosceles containers, then \( t(ABC') = t(ABC'') = t(ABC''') \). Since \( t(BCB_1) = t(BCC'') \), we obtain
\[
(c - b) \sin(\alpha + \beta) = b \sin(\beta - \alpha).
\]
Note that this equation also holds when \( ABC \) is obtuse.

Simple calculation gives \( \frac{c}{b} = \frac{2 \sin(\beta) \cos(\alpha)}{\sin(\alpha + \beta)} \). By Lemma 2.1 (b), the equation \( t(AB'C) = t(ABC') \) reduces to \( \frac{c}{b} = \frac{b}{\sin(\alpha + \beta)} \). Thus, \( \frac{\sin(\beta)}{\sin(\alpha + \beta)} = \frac{2 \sin(\beta) \cos(\alpha)}{\sin(\alpha + \beta)} \), so that \( \sin(\alpha + \beta) = \sin(2\alpha) \). Therefore, either \( \alpha = \beta \), which is impossible, or \( 180^\circ - (\alpha + \beta) = \gamma = 2\alpha \).

It follows from \( \frac{c}{b} = \frac{b}{\sin(\alpha + \beta)} \) that
\[
\frac{\sin(2\alpha)}{\sin(3\alpha)} = \frac{\sin(3\alpha)}{\sin(\alpha)}.
\]
Since \( ABC \) is acute and \( 180^\circ - 3\alpha = \beta < \gamma = 2\alpha \), we have \( 36^\circ < \alpha < 45^\circ \). Simple analysis shows that equation \([3]\) has exactly one solution \( \alpha^* \) in the interval \([36^\circ, 45^\circ]\). It can be approximated by computer.

The other two angles of the corresponding triangle are \( \beta^* = 180^\circ - 3\alpha^* \) and \( \gamma^* = 2\alpha^* \).

**Example 5.1.** By the proof of Theorem 1.6, any minimal area isosceles container for \( ABC \) is either \( AB'C \), or \( AB''C \), or \( AB_1 C \). Here, we construct a family of acute triangles \( ABC \) whose only minimal area isosceles containers are special containers of the second kind, i.e., \( AB_1 C \). Moreover, \( AB_1 C \) is obtuse.

Let \( \alpha > \alpha^* \) and \( 90^\circ > \gamma > 2\alpha > \gamma^* \). Then,
\[
\frac{\sin(\gamma)}{\sin(\beta)} > \frac{\sin(\gamma^*)}{\sin(\beta^*)} = \frac{\sin(\beta^*)}{\sin(\alpha^*)} > \frac{\sin(\beta)}{\sin(\alpha)},
\]
which implies that \( t(AB'C) < t(ABC') \). The triangles \( AB_1 C \) and \( AB'C \) are isosceles with legs of length \( b \), so it is enough to show that \( \sin(\angle ACB_1) = \sin(180^\circ - 2\alpha) < \sin(\gamma) = \sin(\angle ACB') \). However, this follows from the inequalities \( 90^\circ > \gamma > 2\alpha \). The base angle of \( AB_1 C \) satisfies \( \alpha < 45^\circ \), so that \( AB_1 C \) is obtuse.

**Proof of Theorem 1.7 (a):** Let \( r^* \) denote the supremum of the ratio of the area of a minimum area isosceles container of a triangle to the area of the triangle itself. In view of Theorem 1.6, we have
\[
r^* = \sup_{\text{triangle } ABC} \min \left( \frac{t(AB'C)}{t(ABC)}, \frac{t(AB'C)}{t(ABC)}, \frac{t(AB_1 C)}{t(ABC)} \right).
\]

If \( \beta \geq 45^\circ \), then \( \sin(\beta) \geq \frac{1}{\sqrt{2}} \). Using Lemma 2.1(b) and the law of sines, we obtain
\[
\frac{t(ABC')}{t(ABC)} = \frac{c}{b} = \frac{\sin(\gamma)}{\sin(\beta)} \leq \frac{1}{\sqrt{2}} = \sqrt{2}.
\]
Equality holds here if and only if \( \beta = 45^\circ \) and \( \gamma = 90^\circ \), in which case \( ABC \) is an isosceles triangle and the ratio of the area of the minimum isosceles container to the area of \( ABC \) is 1.

If \( \beta < 45^\circ \), then \( \gamma > 90^\circ \). Hence, \( ABC \) is obtuse and, by the proof of Theorem 1.6, the minimum area isosceles container is \( ABC' \) or \( AB_1 C \). For fixed \( \beta \) and \( c \), we can express the ratios of the areas as functions of \( \alpha \). Let
\[
f(\alpha) = \frac{t(ABC')}{t(ABC)} = \frac{c}{b} \quad \text{and} \quad g(\alpha) = \frac{t(AB_1 C)}{t(ABC)} = \frac{2b \cos(\alpha)}{b \cos(\alpha) + a \cos(\beta)} = \frac{1}{\frac{1}{2} + \frac{\tan(\alpha)}{2 \tan(\beta)}},
\]
where \( 0 < \alpha < \beta \). Obviously, \( f(\alpha) \) is strictly increasing and \( g(\alpha) \) is strictly decreasing on the open interval \((0, \beta)\), and both functions are continuous. We have
\[
\lim_{\alpha \to 0^+} f(\alpha) = 1, \quad 1 < \lim_{\alpha \to 0^+} f(\alpha) < 2, \quad \lim_{\alpha \to 0^+} g(\alpha) = 2, \quad \lim_{\alpha \to 0^+} g(\alpha) = 1.
\]
Therefore, the graphs of \( f \) and \( g \) intersect at a unique point \( z \). Thus, \( \max_{0^\circ < \alpha < \beta} (f(\alpha), g(\alpha)) = f(z) = g(z) \), which implies \( t(ABC') = t(AB_1 C) \). This means that \( t(BCB_1) = t(BCC') \), so that equation \([2]\) above holds. Using the law of sines, we obtain \( \frac{c}{b} = 2 \cos(z) < 2 \) and, hence, \( \frac{c}{b} < \sqrt{2} \). If \( \beta \to 0 \), then \( z \to 0 \) and \( c/b \to \sqrt{2} \). This implies that \( r^* = \sqrt{2} \), but the supremum is not realized by any triangle \( ABC \). \(\square\)
