Abstract

We present a complete classification, at the classical level, of the observables of topological Yang-Mills theories with an extended shift supersymmetry of \( N \) generators, in any space-time dimension. The observables are defined as the Yang-Mills BRST cohomology classes of shift supersymmetry invariants. These cohomology classes turn out to be solutions of an \( N \)-extension of Witten’s equivariant cohomology. This work generalizes results known in the case of shift supersymmetry with a single generator.

1 Introduction

The prototype for topological theories of Witten’s type is the four dimensional topological Yang-Mills theory of Witten [1, 2, 3], whose quantum observables are the Donaldson invariants [4]. This model is characterized by a shift invariance, or “shift supersymmetry”, generated by a single scalar fermionic charge, which is interpreted as the BRST invariance describing the nonphysical character of the connection, with the result that only global “observables”, namely the Donaldson invariants, are present. Generalizations to supersymmetry (SUSY) with \( N = 2 \) or more generators where already proposed some years ago in [5, 6, 7] and more recently in [8, 9, 10, 11]. The construction of Lagrangian models for the gauge fixing of the shift supersymmetries may be found in [6] and, for arbitrary \( N \) and arbitrary space-time dimension, in [10, 11]. Most of these constructions are based on a superspace formalism for shift-SUSY introduced first in [12]. There, gauge invariance is formulated in terms of superfields. The Faddeev-Popov ghosts being superfields, supergauge invariance represents invariances with respect to a supermultiplet of local symmetries. However all these local invariances, except the original gauge invariance, may be fixed algebraically in a manner very similar to the Wess-Zumino (WZ) gauge fixing of usual supersymmetric gauge theories [13].

\(^1\)Supported in part by the Conselho Nacional de Desenvolvimento Científico e Tecnológico CNPq – Brazil.
The equivalence of the superspace theory and of the original one, e.g. that of Witten in the $N = 1$ case, is made explicit in this WZ like gauge [6, 14, 10].

The problem of the characterization of the observables of such theories was defined by Witten [1, 15] as the computation of “equivariant cohomology”, i.e. the cohomology of the shift-SUSY generator in the space of the gauge invariant local functionals of the fields. It was shown in [14] that this problem is almost equivalent to the presumably more tractable one of calculating, in the superspace formalism, the cohomology of the BRST operator associated with superspace gauge invariance, in the space of shift-SUSY invariant local functionals. In fact, this equivalence is exact up to solutions which are obviously trivial in the sense of Witten’s equivariant cohomology.

Our purpose is to characterize, for general $N$ and general space-time dimension, and in a formal classical set-up, all the observables defined as solutions of the BRST cohomology for SUSY invariant objects. We will also show that these solutions – up to some of them which turn out to be obviously trivial – are equivalent to solutions of an equivariant cohomology, defined in the WZ-gauge as a generalization of the $N = 1$ definition of Witten.

Section 2 presents an introduction to the superspace formalism, with superfields, superforms, supergauge invariance, superconnection, superghosts and BRST symmetry. The WZ-gauge fixing is recalled in Section 3 where also a generalized definition of equivariant cohomology is proposed. The problem of finding the observables and its solution are explained in Section 4. In Section 5 we write down the general result in the WZ-gauge, show that the integrants of the observables obey a set of generalized Witten’s descent equations and that they are nontrivial in the sense of equivariant cohomology. Our conclusions are presented in Section 6. Superspace conventions and notations are given in Appendix A. Some useful proposition on the relative cohomologies of a general set of $n$ coboundary operators, needed in the main text, are stated and proved in Appendix B. Appendix C contains the proof of another proposition of a more technical character. The WZ-gauge is recalled in Appendix D where a one-to-one correspondence between the fields in this gauge and a set of covariant superfields is constructed.

This paper may be viewed as a continuation of both papers [14] and [10], the first reference dealing with the problem of the observables in the case $N = 1$, and the second one presenting an introduction to the superspace formalism for $N > 1$ and the reduction to the Wess-Zumino gauge. Preliminary results of the present work were presented in [11].

2 $N$-Extended Supersymmetry

“Shift supersymmetry” may describe the gauge fixing of gauge field configurations with null curvature, or alternatively with selfdual curvature. It appeared originally in Donaldson-Witten model [1, 4], with one supersymmetry generator in four dimensional space-time. Generalizations of it for more than one supersymmetry generators and for any space-time dimension were described in [12, 6, 14, 10], where a superspace formalism has been developed. The purpose of this section is to review the formalism and fix the notation.
2.1 $N$ Superspace formalism

$N$ supersymmetry is generated by the fermionic charges $Q_I$, $I = 1, \ldots, N$ obeying the Abelian superalgebra
\[ [Q_I, Q_J] = 0 \, , \tag{2.1} \]
commuting with the space-time symmetry generators and the gauge group generators. The gauge group is some compact Lie group.

A representation of supersymmetry is provided by superspace, a supermanifold with $D$ bosonic and $N$ fermionic dimensions\(^3\). The respective coordinates are denoted by $(x^\mu, \mu = 0, \ldots, D-1)$, and $(\theta^I, I = 1, \ldots, N)$. A superfield is by definition a superspace function $F(x, \theta)$ which transforms as
\[ Q_I F(x, \theta) = \partial_I F(x, \theta) = \frac{\partial}{\partial \theta^I} F(x, \theta) \tag{2.2} \]
under an infinitesimal supersymmetry transformation.

An expansion in the coordinates $\theta^I$ of a generic superfield reads
\[ F(x, \theta) = f(x) + \sum_{n=1}^{N} \frac{1}{n!} \theta^{I_1} \cdots \theta^{I_n} f_{I_1 \cdots I_n}(x) \tag{2.3} \]
where the space-time fields $f_{I_1 \cdots I_n}(x)$ are completely antisymmetric in the indices $I_1 \cdots I_n$. We recall that all fields (and superfields) are Lie algebra valued. These fields and superfields may be generalized to $p$-forms and superfield $p$-forms
\[ \Omega_p(x, \theta) = \omega_p(x) + \sum_{n=1}^{N} \frac{1}{n!} \theta^{I_1} \cdots \theta^{I_n} \omega_{p, I_1 \cdots I_n}(x) \, . \tag{2.4} \]
In (2.3) or (2.4), the components $n \geq 1$ are SUSY transforms of the lowest component. This may be viewed explicitly through the identity
\[ \Omega_p(x, \theta) = \exp \{ \theta^I Q_I \} \omega_p(x) = \sum_{n=0}^{N} \frac{1}{n!} \theta^{I_1} \cdots \theta^{I_n} Q_{I_n} \cdots Q_{I_1} \omega_p(x) \, , \tag{2.5} \]
which holds due to the easily checked superfield property $\partial_I \Omega_p = Q_I \Omega_p$ and the fact that a superfield is uniquely determined by its $\theta = 0$ component.

We shall also deal with superforms. A $q$-superform may be written as
\[ \hat{\Omega}_q = \sum_{k=0}^{q} \Omega_{q-k; I_1 \cdots I_k} d\theta^{I_1} \cdots d\theta^{I_k} \, , \tag{2.6} \]
where the coefficients $\Omega_{q-k; I_1 \cdots I_k}$ are (Lie algebra valued) superfields which are space-time forms of degree $(q-k)$. They are completely symmetric in their indices since, the coordinates $\theta$ being anticommutative, the differentials $d\theta^I$ are commutative. The superspace exterior derivative is defined as
\[ \hat{d} = d + d\theta^I \partial_I \, , \quad d = dx^\mu \partial_\mu \, , \tag{2.7} \]
\(^2\)The bracket is here an anti-commutator. Throughout this paper brackets will denote either commutators or anticommutators, according to the statistics of their arguments.
\(^3\)Notations and conventions on superspace are given in Appendix A.
and is nilpotent: \( \hat{d}^2 = 0 \).

The basic superfield of the theory is the superconnection \( \hat{A} \), a 1-superform:

\[
\hat{A} = A + E_I d\theta^I ,
\]

with \( A = A_\mu(x, \theta) dx^\mu \) a 1-form superfield and \( E_I = E_I(x, \theta) \) a 0-form superfield. The superghost \( C(x, \theta) \) is a 0-superform. We expand the components of the superconnection (2.8) as

\[
A = a(x) + \sum_{n=1}^{N} \frac{1}{n!} \theta^{I_1} \cdots \theta^{I_n} a_{I_1 \cdots I_n}(x) ,
\]

where the 1-form \( a \) is the gauge connection, and the 1-forms \( a_{I_1 \cdots I_n} \) its supersymmetric partners. The expansions of \( E_I \) and of the ghost superfield \( C \) read

\[
E_I = e_I(x) + \sum_{n=1}^{N} \frac{1}{n!} \theta^{I_1} \cdots \theta^{I_n} e_{I_1 \cdots I_n}(x) ,
\]

\[
C = c(x) + \sum_{n=1}^{N} \frac{1}{n!} \theta^{I_1} \cdots \theta^{I_n} c_{I_1 \cdots I_n}(x) .
\]

The infinitesimal supergauge transformations of the superconnection are expressed as the nilpotent BRST transformations

\[
S \hat{A} = -\hat{d} C - [C, \hat{A}] , \quad SC = -C^2 , \quad S^2 = 0 .
\]

In terms of component superfields we have

\[
SA = -dC - [C, A] , \quad SE_I = -\partial_I C - [C, E_I] , \quad SC = -C^2 .
\]

The supercurvature

\[
\hat{F} = \hat{d} \hat{A} + \hat{A}^2 = F_A + \Psi_I d\theta^I + \Phi_{IJ} d\theta^I d\theta^J
\]

transforms covariantly:

\[
S\hat{F} = -[C, \hat{F}] ,
\]

as well as its components

\[
F_A = dA + A^2 , \quad \Psi_I = \partial_I A + D_A E_I , \quad \Phi_{IJ} = \frac{1}{2} (\partial_I E_J + \partial_J E_I + [E_I, E_J]) ,
\]

where the covariant derivative with respect to the connection \( A \) is defined by \( D_A(\cdot) = d(\cdot) + [A, (\cdot)] \).

Special cases, \( N = 1, 2 \) and a discussion of the WZ-gauge can be found in [10].

3 Observables as equivariant cocycles

As discussed in [10] and recalled in Appendix [13] it is possible to suppress all the supergauge degrees of freedom except the usual one corresponding to the \( \theta = 0 \) component \( c \) of the superghost \( C \). This is the so-called “WZ-gauge fixing”, obtained by fixing to zero a set of field components as in (2.11). In the WZ-gauge the supersymmetry generators must be modified into new operators \( \hat{Q}_I \) (2.5).
differing from the previous ones, $Q_I$, by a field dependent gauge transformation. Accordingly, the algebra of the supercharges $\tilde{Q}_I$ closes up to field dependent gauge transformations as in (D.7).

A possible generalization for any $N$ of Witten’s equivariant cohomology $\mathbb{H}$ may be defined as follows, in the WZ-gauge:

– An “equivariant cocycle” is a gauge invariant local field polynomial – integrated or not – obeying to the conditions
\[ \tilde{Q}_I \Delta = 0 \, , \quad I = 1, \cdots , N \, ; \quad (3.1) \]

– A “trivial cocycle” is an equivariant cocycle of the form
\[ \Delta = \tilde{Q}_1 \cdots \tilde{Q}_N \Delta' \, , \quad (3.2) \]

where $\Delta'$ is gauge invariant.

– The “$N$-equivariant cohomology” is the set of equivalence classes of equivariant cocycles corresponding to the equivalence relation
\[ \Delta_1 \approx \Delta_2 \Leftrightarrow \Delta_1 - \Delta_2 \text{ is trivial} \, . \quad (3.3) \]

This suggests the following generalization of Witten’s definition:

**Definition 1** An “observable” is an element of the $N$-equivariant cohomology.

**Remark.** In the superspace formalism, a SUSY invariant has necessarily the form of a total SUSY variation $\Delta = Q_1 \cdots Q_N \Delta'$, as stated in Corollary 1 of Proposition B.4.

### 4 Observables as supersymmetric BRST cocycles

#### 4.1 Defining the problem

Computing the equivariant cohomology defined in the preceding section is presumably a difficult task. Instead of this, we shall generalize to arbitrary $N$ the approach made in [14] for the case $N = 1$, defining observables, in the superspace formalism, as elements of the BRST cohomology in the space of the SUSY invariant space-time integrals of local field polynomials. Our task is thus to define and find global observables, of the form
\[ K \Delta_{(d)} = \int_{M_d} K \omega_{d}^{0} \, , \quad (4.1) \]

integral of a $p$-form on a manifold $M_d$ of dimension $d$. The labels of a form $S \omega_p^g$ are defined as follows. $S$ is a $N$ component vector, with components $(s_1, s_2, \cdots , s_N)$ equal to the (nonnegative) SUSY numbers, $p$ is the (nonnegative) form degree and $g$ is the (nonnegative) ghost number.

---

4The cohomology defined here should not be confused with that of the nilpotent operator $Q = \sum I \epsilon^I Q_I$ or $\tilde{Q} = \sum I \epsilon^I \tilde{Q}_I$, where the $\epsilon^I$ are commuting constant supersymmetry ghosts. The latter may be used in matters such as perturbative renormalization. See e.g. [10] [17] in the context of supersymmetric gauge theories.
The observable \( \Delta_d \) has by definition to satisfy the BRST cocycle condition:

\[ S^K \Delta_d = 0, \quad K \Delta_d \neq S^K \Delta'_d, \quad (4.2) \]

\( K \Delta_d \) and \( K \Delta'_d \) being submitted to the SUSY constraints

\[ Q_I K \Delta_d = 0, \quad Q_I K \Delta'_d = 0, \quad I = 1, 2, \cdots, N \quad (4.3) \]

### 4.2 General solution of the SUSY constraints

We shall solve (4.3) for \( K \Delta_d \), the solution for \( K \Delta'_d \) being analogous. From (4.3) we obtain the following equations for the integrand defined in (4.1):

\[ Q_I^{(k_1, \cdots, k_N)} \omega^0_d + d^{(k_1, \cdots, k_I, 1, \cdots, k_N)} \omega^0_{d-1} = 0, \quad I = 1, 2, \cdots, N \quad (4.4) \]

Using Proposition 4 of Appendix B, we conclude that the general solution is given by

\[ K \omega^0_d = Q_1 \cdots Q_N K^{-E} \omega^0_d + d K^{-E} \varphi^0_{d-1}, \quad (4.5) \]

where \( E \) is the \( N \) dimensional vector \( E = (1, 1, \cdots, 1) \). From the identity \( (2.5) \) obeyed by any superfield and the fact that a product of more than \( N \) operators \( Q_I \) is identically vanishing, we see that we can replace the form \( K^{-E} \omega^0_d \) in (4.5) by the superfield form

\[ K^{-E} \Omega^0_d(x, \theta) = \exp\{\theta^I Q_I\} K^{-E} \omega^0_d(x), \quad (4.6) \]

and thus we can write (4.5) as

\[ K \omega^0_d(x) = Q_1 \cdots Q_N K^{-E} \Omega^0_d(x, \theta) + d K^{-E} \varphi^0_{d-1}, \quad (4.7) \]

and write (4.1) as a superspace integral\(^5\)

\[ K \Delta_d = \oint K^{-E} \Omega^0_d(x, \theta). \quad (4.8) \]

### 4.3 General solution of the BRST cocycle condition

The BRST invariance condition \( (4.2) \) yields, for the integrand of (4.1):

\[ S^{H+E} \omega^0_d + d^{H+E} \omega^1_{d-1} = 0, \]

for some form \( H+E \omega^1_{d-1} \). From our previous result (4.7), this can be rewritten as

\[ S Q_1 \cdots Q_N H \Omega^0_d + d^{H+E} \omega^1_{d-1} = 0. \quad (4.9) \]

For convenience we have redefined the SUSY numbers by putting \( H = (h_1, \cdots, h_N) = K - E = (k_1 - 1, \cdots, k_N - 1) \). Let us show that the second term in the latter equation can also be written as a total SUSY variation. Applying \( Q_I \) to this equation we obtain

\[ dQ_I^{H+E} \omega^1_{d-1} = 0, \quad I = 1, \cdots, N, \]

\(^5\)See the definition given by (A.1) in Appendix A.
hence, due to the triviality of the cohomology of \( d \) in the space of local field functionals \[18\]:

\[
Q_I H + E \omega_{d-1}^I = d(\cdots), \quad I = 1, \cdots, N.
\]

Application of Proposition 4 of Appendix \[13\] with \( \delta_i = Q_I \) and \( \delta_n = d \) then yields

\[
H + E \omega_{d-1}^I = Q_1 \cdots Q_N K^{-E} \Omega_{d-1}^I(x, \theta) + d(\cdots),
\]

and \[13\] takes the form

\[
Q_1 \cdots Q_N \left( S^H \Omega_d^0 + d^H \Omega_d^1 \right) = 0.
\]

Now, application of Proposition 2 of Appendix \[13\] gives

\[
S^H \Omega_d^0 + d^H \Omega_d^1 + \sum_I Q_I H^{-E_I} \Omega_d^I = 0.
\]

We shall show now that we can generate from the latter equation a complete set of “multi-descent equations” – a generalization of the notion of descent equations to the case of more than two antiderivative operators, which are here the operators \( S, d, Q_1, \cdots, Q_N \). In order to do it, it is convenient to work with “truncated superforms” \[14\], a special case of the “truncated extended forms” introduced in Appendix \[C\]. We define a truncated superform of degree \( q \) by

\[
\hat{\Omega}_q = \left[ \hat{\Omega}_q \right]^{(\text{tr})},
\]

where \( \hat{\Omega}_q \) is a \( q \)-superform as defined by \[2.4\], which we may write as

\[
\hat{\Omega}_q = \sum_{S \leq H, |S| = k} \sum_{s_I} S \Omega_{q-k} (d\theta)^S = \sum_{s_I}^{q} \sum_{s_1, \cdots, s_N} (s_1, \cdots, s_N) \Omega_{q-k} (d\theta)^{s_1} \cdots (d\theta)^{s_N},
\]

and where truncation, labeled by the exponent \( (\text{tr})^n \), means discarding, in the expansion \[4.13\], all the terms of degrees \( q - k > d \), \( s_I > h_I \) (\( I = 1, \cdots, I_N \)). Explicitly:

\[
\hat{\Omega}_q = \sum_{k=\text{Max}(0, q-d)}^q \sum_{S \leq H, |S| = k} S \Omega_{q-k} (d\theta)^S,
\]

where \( S \leq H \) means \( s_I \leq h_I \), \( \forall I \). We shall denote by \( \hat{\mathcal{E}}_{(d,H)} \) the space of truncated superforms defined by \[4.12\], \[4.14\].

The exterior derivative \( \tilde{d} \) acting in the space \( \hat{\mathcal{E}}_{(d,H)} \) is defined, according to \[C.3\] (Appendix \[C\]), as

\[
\tilde{d} \hat{\Omega}_q = \left[ \tilde{d} \hat{\Omega}_q \right]^{(\text{tr})}
\]

\[
= \sum_{k=\text{Max}(0, q+1-d)}^q \sum_{S \leq H, |S| = k} d^S \Omega_{q-k} (d\theta)^S + \sum_{I=1}^N \left( \sum_{k=\text{Max}(0, q-d)}^q \sum_{S \leq H^{-E_I}, |S| = k} \partial_1^S \Omega_{q-k} \partial_I^I (d\theta)^S \right).
\]

As shown in Appendix \[C\], \( \tilde{d} \) is nilpotent. Proposition \[C.1\] may be restated as:

\[6\]The second summation in \[4.12\] is performed over all nonnegative values of the SUSY numbers \( s_I \), constrained by \( |S| = k \), where \( |S| = \sum_{I=1}^N s_I \).

\[7\]Recall that all numbers such as form degree, SUSY number and ghost number, are nonnegative. As a general convention, any term which may appear with negative such numbers is understood to vanish.
Lemma 4.1 The cohomology of $\tilde{d}$ in the space $\tilde{\mathcal{E}}_{(d,H)}$ consists of the truncated superforms of maximal weights:

$$\tilde{\Omega}_D = H \Omega_d(d\theta)^H, \quad D \equiv d + |H|.$$  \hfill (4.16)

One checks easily that (4.11) may be written in terms of truncated superforms:

$$\tilde{S} \tilde{\Omega}_D^0 + \tilde{d} \tilde{\Omega}_D^{-1} = 0,$$  \hfill (4.17)

where $D = d + |H|$, and the upper index as usual denotes the ghost number. The two truncated superforms appearing in this equation are

$$\tilde{\Omega}_D^0 = H \Omega_d^0(d\theta)^H, \quad \tilde{\Omega}_D^{-1} = H \Omega_{d-1}^1(d\theta)^H + \sum_{I=1}^{N} H - E_i \Omega_{d}^1(d\theta)^{H-E_i}. \hfill (4.18)$$

Applying $\tilde{d}$ to (4.17), we obtain

$$\tilde{d} \tilde{S} \tilde{\Omega}_D^1 = 0,$$

which, due to the triviality of the cohomology of $\tilde{d}$, solves in

$$\tilde{S} \tilde{\Omega}_D^1 + \tilde{d} \tilde{\Omega}_D^2.$$

Repeating the argument we finally obtain the ($S$, $\tilde{d}$) descent equations

$$\tilde{S} \tilde{\Omega}_D^g + \tilde{d} \tilde{\Omega}_{D-g-1}^{g+1}, \quad g = 0, \ldots, D. \hfill (4.19)$$

These are the “multi-descent equations” which characterize the observable $\tilde{d}$, of dimension $d$ and SUSY weight $H + E$. These equations read, explicitly:

$$S \tilde{\Omega}_p^g + d \tilde{S} \tilde{\Omega}_{p-1}^{g+1} + \sum_{I=1}^{N} Q_I S - E_i \tilde{\Omega}_p^{g+1} = 0,$$  \hfill (4.20)

where $S = (s_1, \ldots, s_N)$, $H = (h_1, \ldots, h_N)$, $|S| = \sum_1^N s_I$, $|H| = \sum_1^N h_I$ and $D = d + |H|$.

4.4 Solving the multi-descent equations

4.4.1 Cohomology of $S$

With the purpose of resolving the multi-descent equations (4.19), our first task will be to resolve the cohomology of the BRST operator $S$ in the space $\mathcal{E}_S$ of the local polynomials in the superfield forms of the theory and of their derivatives, and then in the space $\tilde{\mathcal{E}}_{(d,H)}$ of the truncated superforms (4.12). An obvious algebraic basis of $\mathcal{E}_S$ is given by the set of superfields (2.9-2.10) and their derivatives:

$$\{A, E_I, C, A_{I_1\ldots I_n}, E_{I_1\ldots I_n}, C_{I_1\ldots I_n}, dA, dE_I, dC, dA_{I_1\ldots I_n}, dE_{I_1\ldots I_n}, dC_{I_1\ldots I_n}; n \geq 1\}, \hfill (4.21)$$

*For the case of one SUSY generator (see [14]) they are called bi-descent equations.
where we use the notation $X_{i_1 \cdots i_n} = \partial_{i_1} \cdots \partial_{i_n} X$ for the $\theta$-derivatives.

A more convenient basis is one that consists of BRST doublet superfields and of covariant superfields. The BRST doublets are identified as

$$\left( E_{i_1 \cdots i_n}^{(A)}, K_{i_1 \cdots i_n}^{(A)} \right), \quad n \geq 1, \quad (4.22)$$

where the $E_{i_1 \cdots i_n}^{(A)}$ are the completely antisymmetrized $\theta$-derivatives of $E_i$, and the $K_{i_1 \cdots i_n}^{(A)}$ are their BRST variations:

$$E_{i_1 \cdots i_n}^{(A)} = E_{[i_1, i_2 \cdots i_n]}, \quad K_{i_1 \cdots i_n}^{(A)} = S E_{i_1 \cdots i_n}^{(A)}, \quad SK_{i_1 \cdots i_n}^{(A)} = 0 .$$

The remainder of the basis is given by the set of covariant superfields constructed in Appendix D and shown in Eq. (D.8). A complete algebraic basis is thus provided by:

$$\left\{ E_{i_1 \cdots i_n}^{(A)}, K_{i_1 \cdots i_n}^{(A)}, dE_{i_1 \cdots i_n}^{(A)}, dK_{i_1 \cdots i_n}^{(A)} ; n \geq 1 \right\}$$

$$\bigoplus \left\{ A, C, F_A, dC; \Psi_{i_1 \cdots i_n}^{(A)}(n \geq 1), \Phi_{i_1 \cdots i_n}^{(M)}(n \geq 2), D_A \Psi_{i_1 \cdots i_n}^{(A)}(n \geq 1), D_A \Phi_{i_1 \cdots i_n}^{(M)}(n \geq 2) \right\}$$

A first obvious conclusion is that the fields $E_{i_1 \cdots i_n}^{(A)}$ and $K_{i_1 \cdots i_n}^{(A)}$ and their derivatives do not contribute to the cohomology of $S$, since they are BRST doublets [17]. Moreover, the fields $\Psi_{i_1 \cdots i_n}^{(A)}$ and $\Phi_{i_1 \cdots i_n}^{(M)}$ can be viewed as “matter” fields, transforming in the adjoint representation of the gauge group. Then, as a consequence of the general results of [18], we can conclude that the cohomology of $S$ in the space $E_S$ consists of the local polynomials generated by the cocycles

$$\theta_r(C) \quad (r = 1, \ldots, \text{rank } G) \quad \text{and} \quad P^{\text{inv}}(F, \Psi_{i_1 \cdots i_n}^{(A)}, \Phi_{i_1 \cdots i_n}^{(M)}, D_A \Psi_{i_1 \cdots i_n}^{(A)}, D_A \Phi_{i_1 \cdots i_n}^{(M)}) , \quad (4.24)$$

where $P^{\text{inv}}(\cdots)$ is any gauge invariant polynomial of its arguments, and where $\theta_r$ is the ghost cocycle associated in a standard way [18] to the $r^{\text{th}}$ Casimir operator of the gauge group $G$ and given, as function of the superghost $C$, by

$$\theta_r(C) = (-1)^{m_r-1} \frac{m_r!(m_r-1)!}{g_r!} \text{Tr } C^{g_r} \quad (g_r = 2m_r - 1, \quad r = 1, \ldots, \text{rank } G) , \quad (4.25)$$

where the index $r$ labels the $r^{\text{th}}$ Casimir operator of the structure group (gauge group) $G$, whose degree is denoted by $m_r$. An obvious generalization of the results of [18] shows that the cocycles (4.25) are related by superdescent equations involving superforms $[\hat{\theta}]_{_p}^{g_r-p}$ of form degree $p \geq 0$ and ghost-number $g_r - p$:

$$S \left[ \hat{\theta}_r \right]_{_p}^{g_r-p} + d \left[ \hat{\theta}_r \right]_{p-1}^{g_r-p+1} = 0 \quad (p = 0, \ldots, g_r) , \quad (4.26)$$

with $[\hat{\theta}_r]_0^{g_r} = \theta_r(C)$ and $d [\hat{\theta}_r]_{g_r}^{0} = f_r(\hat{F})$,

where

$$f_r(\hat{F}) = \text{Tr } \hat{F}^{m_r} \quad (r = 1, \ldots, \text{rank } G) , \quad (4.27)$$

9
\( \hat{F} = \hat{d}\hat{A} + \hat{A}^2 \) being the supercurvature \((2.13)\). According to the last of equations \((4.26)\), the “bottom” superform \( [\hat{\theta}_r]^0_g \) is the Chern-Simons superform of degree \( g_r \) associated to the \( r^{th} \) Casimir operator.

A straightforward generalization of the result \((4.24)\) from superfield forms to truncated superforms yields the following lemma:

**Lemma 4.2** The cohomology of \( S \) in the functional space \( \hat{\mathcal{E}}_{(d,H)} \) is given by the truncated forms whose nonvanishing coefficients are polynomials in the superfield forms given in \((4.24)\).

### 4.4.2 Cohomology of \( S \) modulo \( \hat{d} \)

The resolution of the cohomology of \( S \) modulo \( \hat{d} \) in the space \( \hat{\mathcal{E}}_{(d,H)} \) of truncated superforms, i.e. the resolution of the multi-descent equations \((4.19)\) has been done in Appendix A.4 of [14] for the case \( N = 1 \). The computation, relying on the cohomologies of \( \hat{d} \) and \( S \) in \( \hat{\mathcal{E}}_{(d,H)} \) (Lemmas 4.1 and 4.2), applies as well to arbitrary \( N \), thus leading to the proposition:

**Proposition 4.3** The general solution of the multi-descent equations \((4.19)\) corresponding to the observable \((4.7)\) is generated, at ghost-number zero, by two classes of solutions. The first one is given by the superfield forms (recall that \( H = K - E \))

Solution of Type I:

\[
H \Omega^0_d (d\theta)^H = \left[ [\hat{\theta}_r]^0_{g_r} f_r(\hat{F}) \cdots f_L(\hat{F}) \right]_{S=H,p=d}
\]

with \(|H| + d = D\), \( D = 2 \sum_{i=1}^{L} m_{r_i} - 1 \), \( L \geq 1 \),

where the Chern-Simons superform \( [\hat{\theta}_r]^0_{g_r} \) and supercurvature invariant \( f_r(\hat{F}) \) are defined by the equations \((4.25) - (4.27)\).

The second class of solutions depends on the superfield forms \( F, \Psi \) and \( \Phi^{(M)} \) appearing in the cohomology of \( S \) (See \((4.24)\)) and it is given by

Solution of Type II:

\[
H \Omega^0_d = H Z^0_d (F, \Psi^{(A)}_{I_1 \cdots I_n}, \Phi^{(M)}_{I_1 \cdots I_n}, D_A \Psi^{(A)}_{I_1 \cdots I_n}, D_A \Phi^{(M)}_{I_1 \cdots I_n})
\]

Here, \( H Z^0_d \) is an arbitrary invariant polynomial of its arguments, which has a form degree \( d \) and SUSY-numbers given by \( H \), and which is nontrivial in the sense that

\[
H Z^0_d \neq d^H \Phi^0_{d-1} + \sum_{l=1}^{N} Q_l H - E_i \Phi^0_d .
\]

**Remarks.**

1. As in the \( N = 1 \) case [14] the superspace integral (see \((4.8)\)) of any solution of the type \((4.29)\):

\[
K \Delta_d = \oint K - E Z^0_d
\]
which belongs to the BRST cohomology in the space of the SUSY invariant BRST cocycles, is in fact trivial from the point of view of the equivariant cohomology defined in Subsection 3. Indeed, being the space-time integral of a superfield form

\[ K \omega^0_d = -\frac{1}{N!} Q_1 \cdots Q_N K^{-E} Z^0_d, \quad \text{where} \quad K^{-E} Z^0_d \quad \text{is gauge invariant}, \]

it reduces in the WZ-gauge to an equivariantly trivial expression

\[ \int_{M_d} K \omega^0_d = -\frac{1}{N!} \tilde{Q}_1 \cdots \tilde{Q}_N \int_{M_d} K^{-E} z^0_d, \quad \text{where} \quad K^{-E} z^0_d \quad \text{is gauge invariant}. \]

This follows from the fact that the operators \( Q_I \) and \( \tilde{Q}_I \) coincide, when applied to gauge invariant expressions, as seen from (D.5).

2. As we shall see in Section 5, solutions of the type (4.28) are not trivial from the point of view of the equivariant cohomology. In the case \( N = 1 \) [14] they are the Witten-Donaldson observables [1]. The cases \( N > 1 \) offer thus a generalization of the latter.

### 4.5 Superform expression of the observables

Let us consider the untruncated version of the equations (4.19) involving full superforms (see (2.6)):

\[ S \hat{\Omega}_{D-g}^g + d \hat{\Omega}_{D-g-1}^{g+1}, \quad g = 0, \ldots, D \quad (D = |H| + d). \quad (4.30) \]

It can be shown [14] on the basis of the results of [18] about BRST cohomology, that the general solution of the super-descent equations (4.30) which contains superforms down to and including ghost number \( g = 0 \), is given by

\[ \hat{\Omega}_{D-g_{r_1}+p}^{g_{r_1}+p} = \left[ \hat{\theta}_{r_1} \right]_{p}^{g_{r_1}+p} f_{r_2}(\hat{F}) \cdots f_{r_L}(\hat{F}), \quad p = 0, \ldots, g_{r_1}, \quad (4.31) \]

with the \( \left[ \hat{\theta}_{r_1} \right]_{p}^{g_{r_1}+p} \) and the supercurvature invariant \( f_c(\hat{F}) \) defined by the equations (4.25) - (4.27). The superfield components \( S \hat{\Omega}_{p}^g \), with \( |S| + g + p = D \), of these superforms are clearly solutions of the multi-descent descent equations (4.19) since the latter is a subsystem of (4.30). The corresponding observables are given by the superspace integrals of the superfield components of the expansion

\[ \hat{\Omega}_D^0 = \left[ \hat{\theta}_{r_1} \right]_{g_{r_1}}^0 f_{r_2}(\hat{F}) \cdots f_{r_L}(\hat{F}) \equiv \sum_{H}^{H \leq D} H \hat{\Omega}_D^H (d\theta)^H, \quad (4.32) \]

i.e. (see (4.1) and (4.8))

\[ K \Delta_d = H \hat{\Omega}_D^0, \quad d = D - |H|, \quad K = H + (1, \cdots, 1). \quad (4.33) \]

On the other hand, we see from the equations (4.32) taken with all possible values of \( D \) and of the numbers \( g_{r_1} \) that the components of the solutions of the superdescent equations (4.30) span all the solutions of type I (4.28) of the multidescent equations (4.19). Thus:
Proposition 4.4 Let $\hat{\Omega}^0_D$ represent the general solution of the super-descent equations (4.30). Then the superfield forms $\hat{\Omega}^0_{D-|H|}$ defined by the expansion of $\hat{\Omega}^0_D$ in (4.32) represent the general solution of type (4.28) of the multi-descent equations (4.19).

We note for the sake of completeness that the superforms $\hat{\Omega}^{g_{r_1}-p}_{D-g_{r_1}+p}$ obey the system of superdescent equations

\[ S\hat{\Omega}^{g_{r_1}-p}_{D-g_{r_1}+p} + d\hat{\Omega}^{g_{r_1}-p+1}_{D-g_{r_1}+p-1}, \quad p = 0, \ldots, g_{r_1}, \]

involving ghost numbers up to the value $g_{r_1}$, which is less than the maximum possible value $D$ if $L > 2$.

A convenient way of representing the observables (4.33) and deducing interesting properties of them, is based on the identity $\hat{d} \left[ \theta_{r_1} \right]_0^0 = f_{r_1}(\hat{F})$ for the Chern-Simons form, and the expansion

\[ \hat{d}\hat{\Omega}^0_D = f_{r_1}(\hat{F}) \cdots f_{r_L}(\hat{F}) = f_{r_1}(F) \cdots f_{r_L}(F) + \sum_{S}^{1 \leq |S| \leq D+1} S W^0_{D+1-|S|} (d\theta)^S, \]  

(4.34)

with the first term being a $d$-derivative, and

\[ S W^0_{D+1-|S|} = \sum_{l=1}^{N} Q_l S^{-E_l} \Omega^0_{D+1-|S|} + d S \Omega^0_{D-|S|}. \]  

(4.35)

Integrating both sides of the latter equation in superspace, we see that we can write (4.33) as

\[ K \Delta_d = \oint \hat{H} \Omega^0_d = (-1)^{N-J} \int_{M_d}^{\infty} Q_1 \cdots \hat{Q}_J \cdots Q_N H^{+E_J} W^0_d, \]  

(4.36)

with $H = K - E$, $d = D - |H| = D + N - K$,

where the notation $\hat{X}$ means suppression of the factor $X$. The value of $J$ in the right-hand side is arbitrary. Let us show that the expression is in fact independent of $J$ as it should. Applying the nilpotent operator $\hat{d}$ on (4.34) we obtain the descent equations

\[ \sum_{l=1}^{N} Q_l H^{-E_l} W^0_{D+2-|H|} + d H W^0_{D+1-|H|} = 0, \quad 1 \leq |H| \leq D + 1, \]  

(4.37)

\[ \sum_{l=1}^{N} Q_l H^{-E_l} W^0_0 = 0, \quad |H| = D + 2 . \]

Considering the difference of the expressions (4.36) obtained for two values of $J$, which we may choose without loss of generality as $J = N$ and $J = N - 1$, respectively, we obtain

\[ \int_{M_d}^{\infty} Q_1 \cdots Q_{N-2} \left( Q_{N-1} H^{-E_{N-1}} W^0_d + Q_N H^{-E_N} W^0_d \right), \quad H' = H + E_N + E_{N-1} , \]

which, by virtue of (4.37) for $|H| = D + 2 - d$, reads

\[ -\int_{M_d}^{\infty} Q_1 \cdots Q_{N-2} \sum_{l=1}^{N-2} Q_l H^{-E_l} W^0_d = 0, \]

and which vanishes due to the nilpotency of the operators $Q_l$. 

12
Witten’s observables and descent equations

Let us rewrite the integral (4.36), expressing a generic observable, as a space-time integral:

\[ K | M d K \omega_d + \int M d K \omega_d, \quad (5.1) \]

the integrant being defined up to a total space-time derivative. Let us define the latter as

\[ K \omega_d = \sum_{J=1}^N (-1)^{N-J} \alpha_J Q_1 \cdots Q_J \cdots Q_N H^{E_J} W_d^0 \bigg|_{\theta=0}, \quad \text{with} \quad \sum_J \alpha_J = 1. \quad (5.2) \]

It is clear from the discussion at the end of last Subsection that, to the contrary of its integrant, the integral does not depend on the arbitrary numbers \( \alpha \). Calculating

\[ Q_I K \omega_d = (-1)^{N-1} \alpha_I Q_1 \cdots Q_N H^{E_I} W_d^0, \]

and

\[ d K^{E_I} \omega_{d-1} = \sum_{J=1}^N (-1)^{J-1} \alpha_J Q_1 \cdots Q_J \cdots Q_N d^{H^{E_J+E_I}} W_{d-1}^0 \bigg|_{\theta=0} = (-1)^N \alpha_I Q_1 \cdots Q_N H^{E_I} W_d^0, \]

where we have used (4.37) for the last equality, we conclude that the integrants (5.2) obey the descent equations

\[ Q_I K \omega_d + \alpha_I d K^{E_I} \omega_{d-1} = 0, \quad I = 1, \cdots, N, \quad N \leq |K| \leq D - d + N. \quad (5.3) \]

We can now go to the WZ-gauge (see Appendix D). The forms \( K \omega_d \) being gauge invariant functions of the covariant superfields (D.8) taken at \( \theta = 0 \), they reduce to correspondent gauge invariant functions of the covariant WZ-gauge fields (D.2) by virtue of the correspondence (D.10). Moreover, since the expressions are gauge invariant, the applications of generators \( \tilde{Q}_I \) and \( Q_I \) are identical. Hence, the equations (5.3) reduce to

\[ \tilde{Q}_I K \omega_d + \alpha_I d K^{E_I} \omega_{d-1} = 0, \quad I = 1, \cdots, N, \quad N \leq |K| \leq D - d + N, \quad (5.4) \]

which are the possible generalizations to arbitrary \( N \) of Witten’s descent equations [1].

Specializing to two particular values of the set of numbers \( \alpha_I \), we would obtain:

\[
\begin{align*}
\tilde{Q}_I K \omega_d + \frac{1}{N} d K^{E_I} \omega_{d-1} & = 0 \quad (\alpha_I = \frac{1}{N}), \\
\tilde{Q}_J K \omega_d + d K^{E_J} \omega_{d-1} & = 0 \quad (\alpha_J = 1, \ \alpha_I = 0, \ I \neq J).
\end{align*}
\]

Let us recall that in all systems of equations above, any term with negative SUSY number or form degree is assumed to vanish.

The equations (5.4) show that our solutions, which solve Witten’s descent equations, are indeed Witten’s observables, their space-time integrals being \( \tilde{Q}_I \)-invariant for any \( I \). It remains to show that they are nontrivial in the sense defined in Section 3. For this it is sufficient to check the
nontriviality of the \( w \)'s of highest SUSY numbers (hence of zero form degree). The latters are \( \tilde{Q}_I \) invariant, and read (see e.g. \( \text{(5.2)} \) for \( \alpha_1 = 1, \alpha_I = 0, I \neq 1, \) and \( \text{(4.34)} \))

\[
I_1J_1\cdots I_nJ_n w_0 = (-1)^{N-1} Q_2 \cdots Q_N \left( \Phi_{I_1J_1}, \cdots, \Phi_{I_nJ_n} \right) \bigg|_{\text{symmetrized in } (I_1, \cdots, J_n)}, \quad \text{with } n = \sum_{r=1}^{L} m_r ,
\]

where we use the notation \( \text{(4.13)} \) and \( \Phi_{I_1, \cdots, J_n} \) is a symmetric invariant polynomial of its arguments. In the WZ-gauge:

\[
I_1J_1\cdots I_nJ_n w_0 = (-1)^{N-1} \tilde{Q}_2 \cdots \tilde{Q}_N \left( e^M_{I_1J_1}, \cdots, e^M_{I_nJ_n} \right) \bigg|_{\text{symmetrized in } (I_1, \cdots, J_n)}, \quad \text{with } n = \sum_{r=1}^{L} m_r .
\]

It is easy to check that the \( e^M_{IJ} \) can never be written as a \( \tilde{Q}_1 \)-variation. Hence \( w_0 \) cannot be written as a full \( \tilde{Q}_1\tilde{Q}_2 \cdots \tilde{Q}_N \)-variation and thus belongs to the equivariant cohomology.

## 6 Conclusion and open problems

The results on the classification of the observables known for the topological Yang-Mills theories with one supersymmetry generator, were generalized to the case of theories defined with more supersymmetry generators. We have obtained a complete classification of the observables according to their definition as nontrivial BRST cocycles in the space of supersymmetry invariant local functionals.

Although our solutions are solutions of the equivariant cohomology problem defined in Section 3 we have no proof that it provides the complete solution of the latter. However, we have also found generalized Witten’s descent equations for the integrants of the observables and showed their nontriviality in the equivariant cohomology sense.

Our results are formal, being established in the classical approximation. Their interpretation at the quantum level as topological invariants remains an open problem in the general case of arbitrary numbers of SUSY generators and space-time dimensions, although some results are known for special cases, in particular for \( N = 2 \) \([6, 9]\).

**Acknowledgements.** We are much indebted to José Luiz Boldo for his collaboration at a preliminary stage of this work, and to José Alexandre Nogueira and Wander G. Ney for many useful discussions. C.P. Constantinidis would like to thank the Abdus Salam International Center of Theoretical Physics (ICTP) for hospitality during a visit under the Associate Program.
Appendices

A \textit{N- supersymmetry and superspace}

(D, N)-superspace bosonic coordinates are denoted by $x^\mu, \mu = 0, \ldots, D-1$, the fermionic (Grassmann, or anticommuting) coordinates being denoted by $\theta^I, I = 1, \ldots, N$. The $N$ supersymmetry generators $Q_I$ are represented on superfields $F(x, \theta)$ by

$$Q_I F = \partial_I F \equiv \frac{\partial}{\partial \theta^I} F,$$

where, by definition, $\partial_K \theta^J = \delta^J_K$. Further conventions and properties about the $\theta$-coordinates are the following:

$$\theta^N = \epsilon^{I_1 \cdots I_N} \theta^{I_1} \cdots \theta^{I_N} = N! \theta^{1} \cdots \theta^{N},$$

$$(\partial_\theta)^N = \epsilon^{I_1 \cdots I_N} \partial_{I_1} \cdots \partial_{I_N} = N! \partial_1 \cdots \partial_N,$$

$$(\partial_\theta)^N \theta^N = -(N!)^2,$$

where $\epsilon^{I_1 \cdots I_N}$ is the completely antisymmetric tensor of rank $N$, with the conventions

$$\epsilon^{1 \cdots N} = 1, \quad \epsilon^{I_1 \cdots I_N} = (-1)^{N+1} \epsilon^{I_1 \cdots I_N}.$$

One may define the conserved supersymmetry number – \textit{SUSY number} – attributing the value 1 to the generators $Q_I$, hence $-1$ to the $\theta$-coordinates. The SUSY number of each field component is then deduced from the SUSY number given to each superfield.

Superspace integration of a superfield form $\Omega_p(x, \theta)$ is defined by integrals

$$\oint \Omega_p(x, \theta) = \int_{M_p} \int d^N \theta \Omega_p(x, \theta),$$

where the $x$-space integral is made on some $p$-dimensional (sub)manifold $M_p$, and the $\theta$-space integral is the Berezin integral defined by

$$\int d^N \theta \cdots = -\frac{1}{(N!)^2} (\partial_\theta)^N \cdots,$$

such that $\int d^N \theta \theta^N = 1$.

B \textit{Some useful propositions}

The propositions and proofs presented here are generalizations of results given in [IS]. They hold for both usual forms and superfield forms.

\textbf{Definitions and notations.} Let $\omega^{(s_1, \cdots, s_n)}$ be forms whose weights $s_i$ are associated to $n$ operators $\delta_i, (i = 1, \cdots, n)$, nilpotent and anticommuting, i.e., $\{\delta_i, \delta_j\} = 0$. The cohomology group of each
operator \( \delta_i \) is trivial by hypothesis. If some of the weights \( s_i \) are negative we have, by convention, 
\[ \omega^{(s_1, \cdots, s_n)} = 0. \]
We shall use the condensed notations
\[
\omega^S, \quad S = (s_1, \cdots, s_n), \quad |S| = \sum_{i=1}^{n} s_i, \\
E_i = (0, \cdots, 1, \cdots, 0) \quad \text{(unique nonvanishing component is a 1 at the } i^{\text{th}} \text{ position)}, \\
E = \sum_{i=1}^{n} E_i = (1, 1, \cdots, 1), \\
S - T = (s_1 - t_1, \cdots, s_n - t_n), \quad S \leq T \iff s_i \leq t_i, \ i = 1, \ldots, n.
\]
The forms \( \omega^S \) may be fields or superfields.

**Proposition B.1** Let the set of forms \( \{ \omega^{T-E_i} \}_i \) satisfy the cocycle condition
\[
\sum_{i=1}^{n} \delta_i \omega^{T-E_i} = 0. \tag{B.2}
\]

1. The set \( \{ \omega^{T-E_i} \}_i \) can be extended to an extended form \( \tilde{\omega} \), defined by
\[
\tilde{\omega} = \sum_{S} \omega^S, \tag{B.3}
\]
such that
\[
\tilde{\delta} \tilde{\omega} = 0; \quad \tilde{\delta} = \sum_{i=1}^{n} \delta_i. \tag{B.4}
\]

2. There exists an extended form
\[
	ilde{\varphi} = \sum_{S} \varphi^S, \tag{B.5}
\]
where \( \tilde{\omega} \) and \( \tilde{\varphi} \) satisfy
\[
\tilde{\omega} = \tilde{\delta} \tilde{\varphi}. \tag{B.6}
\]

**Corollary 1** The cohomology of \( \tilde{\delta} \) is trivial.

**Corollary 2** The general solution of (B.2) for any \( \omega^{T-E_i} \) is given by
\[
\omega^{T-E_i} = \sum_{j=1}^{n} \delta_j \varphi^{T-E_i-E_j}, \quad j = 1, \cdots, n, \tag{B.7}
\]
where all \( \varphi^{T-E_i-E_j} \) for \( i, j = 1, \cdots, n \) are components of a single extended form \( \tilde{\varphi} \).

**Proof of Proposition B.1.** The proof will be performed by induction from the case \( n = 2 \) which will be first treated explicitly.
**Case** $n = 2$. In this case, equation (B.2) is given by
\[ \delta_1 \omega^{(t_1-1,t_2)} + \delta_2 \omega^{(t_1,t_2-1)} = 0. \] (B.8)

**Proof of Part 1.** Applying \( \delta_1 \) to (B.8) we obtain: \( \delta_2 \delta_1 \omega^{(t_1,t_2-1)} = 0 \). Remembering that the cohomology of \( \delta_2 \) is trivial, we deduce the existence of a form \( \omega^{(t_1+1,t_2-2)} \), such that:
\[ \delta_1 \omega^{(t_1,t_2-1)} + \delta_2 \omega^{(t_1+1,t_2-2)} = 0. \] (B.9)

Repeating successively this procedure we finally get
\[ \delta_1 \omega^{(|T|-1,0)} = 0, \quad |T| = t_1 + t_2. \] (B.10)

We have thus obtained the set of equations
\[ \delta_1 \omega^{(t_1+k-1,t_2-k)} + \delta_2 \omega^{(t_1+k,t_2-k-1)} = 0, \quad 0 \leq k \leq t_2. \]

Applying now \( \delta_2 \) to (B.8) and using the triviality of the cohomology of \( \delta_1 \), we obtain in an analogous way the following equations
\[ \delta_1 \omega^{(t_1-k'-1,t_2+k')} + \delta_2 \omega^{(t_1-k',t_2+k'-1)} = 0, \quad 0 \leq k' \leq t_1. \]

These last two systems of equations can be put into a unique set:
\[ \delta_1 \omega^{(t_1+p-1,t_2-p)} + \delta_2 \omega^{(t_1+p,t_2-p-1)} = 0, \quad -t_1 \leq p \leq t_2, \] (B.11)

which is exactly (B.4) written in components, corresponding to the extended form and to the extended operator
\[ \tilde{\omega} = \sum_{p=-t_1}^{t_2} \omega^{(t_1+p-1,t_2-p)}, \quad \tilde{\delta} = \delta_1 + \delta_2. \] (B.12)

**Proof of part 2.** Equation (B.11) for \( p = -t_1 \) is (B.10). From the triviality of the cohomology of \( \delta_2 \) we obtain the general solution
\[ \omega^{(0,|T|-1)} = \delta_2 \varphi^{(0,|T|-2)}, \] (B.13)

and by substituting (B.13) in (B.11) for \( p = -t_1 + 1 \), we obtain
\[ \delta_2 \left[ -\delta_1 \varphi^{(0,|T|-2)} + \omega^{(1,|T|-2)} \right] = 0, \] (B.14)

whose general solution for \( \omega^{(1,|T|-2)} \) is
\[ \omega^{(1,|T|-2)} = \delta_1 \varphi^{(0,|T|-2)} + \delta_2 \varphi^{(1,|T|-3)}. \] (B.15)

The procedure continues until equation (B.11) for \( p = t_2 - 1 \), leading finally to
\[ \omega^{(t_1+p-1,t_2-p)} = \delta_1 \varphi^{(t_1+p-2,t_2-p)} + \delta_2 \varphi^{(t_1+p-1,t_2-p-1)}, \quad -t_1 + 1 \leq p \leq t_2. \] (B.16)

with the last equation, for \( p = t_2 \), being identically satisfied. Notice that the set (B.11) can be put in the form (B.6) with
\[ \tilde{\varphi} = \sum_{p=-t_1+2}^{t_2} \varphi^{(t_1+p-2,t_2+p)} \]. (B.17)
The general case

In order to establish the proof for general $n$ we suppose that the proposition is valid for $(n - 1)$. Applying for example $\delta_1$ on (B.2), we get

$$\sum_{i=2}^{n} \delta_i \omega^{(t_1,t_2,\ldots,t_{i-1},\ldots,t_n)} = 0 .$$

(B.18)

By the induction hypothesis there exists $(n - 1)$ forms $\omega^{(t_1+1,t_2-2,t_3,\ldots,t_n)}$ and $\omega^{(t_1+1,t_2-1,t_3,\ldots,t_{i-1},\ldots,t_n)}$, with $i = 3, \ldots, n$, such that

$$\delta_1 \omega^{(t_1,t_2-1,t_3,\ldots,t_n)} + \delta_2 \omega^{(t_1+1,t_2-2,t_3,\ldots,t_n)} + \sum_{i=3}^{n} \delta_i \omega^{(t_1+1,t_2-1,t_3,\ldots,t_{i-1},\ldots,t_n)} = 0 .$$

(B.19)

Repeating the procedure we get

$$\delta_1 \omega^{(t_1+k-1,t_2-k,t_3,\ldots,t_n)} + \delta_2 \omega^{(t_1+k,t_2-k-1,t_3,\ldots,t_n)} + \sum_{i=3}^{n} \delta_i \omega^{(t_1+k,t_2-k-1,t_3,\ldots,t_{i-1},\ldots,t_n)} = 0 ,$$

(B.20)

with $0 \leq k \leq t_2$. Beginning the same procedure from (B.2), but applying $\delta_2$ and considering the cohomology of $\delta_1, \delta_3, \ldots, \delta_n$, we obtain

$$\delta_1 \omega^{(t_1-k',t_2+t',t_3,\ldots,t_n)} + \delta_2 \omega^{(t_1-k',t_2+t',t_3,\ldots,t_n)} + \sum_{i=3}^{n} \delta_i \omega^{(t_1-k',t_2+t',t_3,\ldots,t_{i-1},\ldots,t_n)} = 0 ,$$

(B.21)

$$0 \leq k' \leq t_1 .$$

We can unify the last two set of equations in the following one

$$\delta_1 \omega^{(t_1+p-1,t_2-p,t_3,\ldots,t_n)} + \delta_2 \omega^{(t_1+p,t_2-p-1,t_3,\ldots,t_n)} + \sum_{i=3}^{n} \delta_i \omega^{(t_1+p,t_2-p-1,t_3,\ldots,t_{i-1},\ldots,t_n)} = 0 ,$$

(B.22)

$$-t_1 \leq p \leq t_2 .$$

Introducing now the 2–extended operator $\tilde{\delta}_{(1,2)} = \delta_1 + \delta_2$ and the sets of 2–extended forms

$$\omega^{(f,t_3,\ldots,t_{i-1},\ldots,t_n)}_{(1,2)} = \sum_{s_1+s_2=f}^{s_1+s_2=t} \omega^{(s_1,s_2,t_3,\ldots,t_{i-1},\ldots,t_n)}, \quad i = 3, \ldots, n ,$$

$$\omega^{(h-1,t_3,\ldots,t_n)}_{(1,2)} = \sum_{s_1,s_2}^{s_1+s_2=t-1} \omega^{(s_1,s_2,t_3,\ldots,t_n)},$$

we can rewrite (B.22) as:

$$\tilde{\delta}_{(1,2)} \omega^{(\tilde{f},t_3,\ldots,t_n)}_{(1,2)} + \sum_{i=3}^{n} \delta_i \omega^{(\tilde{f},t_3,\ldots,t_{i-1},\ldots,t_n)} = 0 , \quad \tilde{t} = t_1 + t_2 .$$

(B.24)

Observe that the operator $\tilde{\delta}_{(1,2)}$ is nilpotent and anticommutes with the others $\delta_i$. By virtue of Proposition (B.1) already proved for the case $n = 2$, its cohomology is trivial. In order to solve
(B.24) we make use of Proposition B.1 true for \((n-1)\), by assumption, where the \((n-1)\) operators are given by \(\{\tilde{\delta}_{(1,2)}, \delta_3, \cdots, \delta_n\}\). We have thus the extended form

\[
\tilde{\omega}^{(\tilde{s},s_3,\cdots,s_n)}_{(1,2)} = \sum_{\tilde{s},s_3,\cdots,s_n} \omega^{(s_1,\cdots,s_n)} = \tilde{\omega},
\]

satisfying (B.2):

\[
\left(\tilde{\delta}_{(1,2)} + \sum_{i=3}^{n} \delta_i\right) \tilde{\omega} = 0, \quad \tilde{\delta} = \sum_{i=1}^{n} \delta_i.
\]

We also know from part 2 of Proposition B.1 for \((n-1)\) that there exists an extended form

\[
\tilde{\varphi} = \sum_{\tilde{s},s_3,\cdots,s_n} \tilde{\varphi}^{(\tilde{s},s_3,\cdots,s_n)}_{(1,2)} = \sum_{s_1,\cdots,s_n} \varphi^{s_1,\cdots,s_n} = \tilde{\varphi},
\]

which satisfies

\[
\tilde{\varphi} = \left(\tilde{\delta}_{(1,2)} + \sum_{i=3}^{n} \delta_i\right) \tilde{\varphi} = \tilde{\delta} \tilde{\varphi}.
\]

Proposition B.2 If the form \(\omega = \omega^T = \omega(t_1,\cdots,t_n)\) satisfies the equation

\[
\delta_1 \cdots \delta_n \omega = 0,
\]

it admits a solution of the type

\[
\omega = \sum_{i=1}^{n} \delta_i \varphi^T E_i.
\]

Proof of Proposition B.2. The proof is by induction. For the case \(n = 1\) equation (B.27) reads \(\delta \omega = 0\), and from the triviality of the cohomology of \(\delta\) the solution is given by

\[
\omega = \delta \varphi.
\]

For the general case, we can rewrite (B.27) as

\[
(\delta_1 \cdots \delta_{n-1}) \delta_n \omega = 0,
\]

and supposing that Proposition B.2 is valid for \((n-1)\), we can solve (B.29) with respect to \(\delta_n \omega\), obtaining

\[
\delta_n \omega(t_1,\cdots,t_{n-1}) = \sum_{i=1}^{n-1} \delta_i \eta^T E_i.
\]

From Proposition B.1 it follows that

\[
\omega = \sum_{i=1}^{n} \delta_i \varphi^T E_i.
\]
Proposition B.3 If the form \( \omega^T = \omega^{(t_1, \ldots, t_n)} \) satisfies the following equation,
\[
\delta_1 \cdots \delta_{n-1} \omega^T + \delta_n \psi^T + E_1 + \cdots + E_{n-1} - E_n = 0 ,
\] (B.32)
the general solution for it is given by
\[
\omega^T = \sum_{i=1}^{n} \delta_i \varphi^{T-E_i} .
\] (B.33)

Proof of Proposition B.3 Applying \( \delta_n \) on (B.32) we have
\[
\delta_1 \cdots \delta_{n-1} \delta_n \omega^T = 0 ,
\]
whose solution is (B.33) by virtue of Proposition B.2.

Proposition B.4 If the form \( \omega^T = \omega^{(t_1, \ldots, t_n)} \) satisfies the following set of equations
\[
\delta_i \omega^T + \delta_n \psi^T + E_i - E_n = 0 , \quad i = 1, \cdots, n-1 ,
\] (B.34)
the general solution is given by
\[
\omega^T = \delta_1 \cdots \delta_{n-1} \varphi^{T-E_1 - \cdots - E_{n-1}} + \delta_n \eta^{T-E_n} .
\] (B.35)

Corollary 1 Let \( \omega^T = \omega^{(t_1, \cdots, t_n)} \), obeys the following set of equations
\[
\delta_i \omega^T = 0 , \quad i = 1, \cdots, n .
\] (B.36)
The general solution for (B.36) is
\[
\omega^T = \delta_1 \cdots \delta_n \varphi^{T-E_1 - \cdots - E_n} .
\] (B.37)

Proof of Proposition B.4 From Proposition B.1 we write the solution for the first equation of the set (B.34):
\[
\omega^T = \delta_1 \varphi^{T-E_1} + \delta_n (\cdots) .
\] (B.38)
Substituting it into the second equation of (B.34) we have
\[
\delta_2 \delta_1 \varphi^{T-E_1} + \delta_n (\cdots) = 0 .
\] (B.39)
From Proposition B.3 we get the solution for (B.39):
\[
\varphi^{T-E_1} = \delta_1 \varphi^{T-2E_1} + \delta_2 \varphi^{T-E_1 - E_2} + \delta_n (\cdots) .
\] (B.40)
Substituting (B.40) into (B.38) we arrive at
\[
\omega^T = \delta_1 \delta_2 \varphi^{T-E_1 - E_2} + \delta_n (\cdots) .
\] (B.41)
Repeating the argument we finally obtain the result (B.35).
C Truncated extended forms and cohomology

Let us consider as in Appendix B forms $\phi^R = \phi^{(r_1, \ldots, r_n)}$, which may be fields or superfields. The notations and conventions are explained in the beginning of that appendix. The nilpotent extended operator $\tilde{\delta}$ and an extended $q$-form of total weight $q$ are defined as

$$\tilde{\delta} = \sum_{i=1}^{n} \delta_i, \quad \tilde{\phi}^q = \sum_{R} \phi^R. \quad (C.1)$$

Let us define the truncated extended $q$ forms associated to the heighest $H = (h_1, \ldots, h_n)$ (in short: truncated forms) as

$$\tilde{\phi}^q = \left[ \tilde{\phi}^q \right]^{(tr)} = \sum_{R \leq H} \phi^R. \quad (C.2)$$

The truncation, indicated by the exponent $^{(tr)}$, means discarding in the expression all the forms of degree not constrained by $R \leq H$. The polynomials in these truncated forms and their truncated exterior derivatives span the space $\tilde{\mathcal{E}}_H$, with the exterior multiplication and derivation rules

$$\tilde{\phi}^q_1 \tilde{\phi}^q_2 = \left[ \tilde{\phi}^q_1 \tilde{\phi}^q_2 \right]^{(tr)} \quad \text{and} \quad \tilde{\delta} \tilde{\phi}^q = \left[ \tilde{\delta} \tilde{\phi}^q \right]^{(tr)}. \quad (C.3)$$

$\tilde{\delta}$ is obviously nilpotent, and the operations defined in (C.3) map $\tilde{\mathcal{E}}_H$ to $\tilde{\mathcal{E}}_H$.

**Proposition C.1** The cohomology of $\tilde{\delta}$ in the space $\tilde{\mathcal{E}}_H$ consists of the highest weight truncated forms

$$\tilde{\phi}^{[H]} = \phi^H, \quad \tilde{\phi}^{[H]} \neq \tilde{\delta} \tilde{\phi}^{[H]-1}. \quad (C.4)$$

**Remark.** A highest weight truncated form $\tilde{\phi}^{[H]}$ is always closed: $\tilde{\delta} \tilde{\phi}^{[H]} = 0$.

**Proof of Proposition C.1.** The proof is by induction. The result being obvious for $n = 1$, we shall prove it for the generic case $n$ assuming it to hold for $n - 1$. Let us divide the weights $r_1, \ldots, r_n$ in two subsets: $r_1$ and $R' = (r_2, \ldots, r_n)$. We define accordingly the partially extended operator $\tilde{\delta}'$ and the partially extended forms

$$\tilde{\delta}' = \sum_{i=2}^{n} \delta_i, \quad \tilde{\phi}'^{(q-r,r)} = \sum_{R'} \phi^{(q-r,R')}, \quad r = 0, \ldots, q, \quad (C.5)$$

as well as the partially truncated extended forms

$$\tilde{\phi}'^{(q-r,r)} = \left[ \tilde{\phi}'^{(q-r,r)} \right]^{(tr)} = \sum_{R' \leq H} \phi^{(q-r,R')}, \quad r = 0, \ldots, q, \quad (C.6)$$

on which act the partially truncated derivative $\tilde{\delta}'$ defined by

$$\tilde{\delta}' \tilde{\phi}'^{(q-r,r)} = \left[ \tilde{\delta}' \tilde{\phi}'^{(q-r,r)} \right]^{(tr)} = \sum_{i=2}^{n} \left( \sum_{R'} \delta_i \phi^{(q-r,R')} \right), \quad r = 0, \ldots, q. \quad (C.7)$$

21
From the induction hypothesis, the cohomology of $\tilde{\delta}'$ is trivial in the subspace of the partially truncated forms (C.7) restricted by the condition $r < h'$. 

Let us now solve the cohomology equation

$$\tilde{\delta} \tilde{\phi}^q = 0 .$$

(C.8)

The truncated form (C.2), can be written as

$$\tilde{\phi}^q = \sum_{r=\max(0,q-h_1)}^{\min(q,h')} \tilde{\phi}^{q-r,r} .$$

(C.9)

We have thus to examine separately the four cases $0 \leq q < h_1$, $h_1 \leq q < h'$, $h' \leq |H| < h_1$, $q = |H| = h_1 + h'$, corresponding respectively to the areas (1), (2), (3) and to the point (4) of the figure C.1.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure.png}
\caption{Weight diagram for the partially truncated superforms $\tilde{\phi}^{r}(r_1,r'_{r})$. The numbers (1), (2), (3) and (4) refer to the 4 cases examined in the text.}
\end{figure}

Case 1: $0 \leq q < h_1$. We have

$$\tilde{\phi}^q = \sum_{r=0}^{q} \tilde{\phi}^{(q-r,r)} , \quad \tilde{\delta} \tilde{\phi}^q = \sum_{r=0}^{q} (\delta_1 + \tilde{\delta}') \tilde{\phi}^{(q-r,r)} .$$

The cohomology condition (C.8) implies the following equations

$$\delta_1 \tilde{\phi}^{(q,0)} = 0 ,$$

$$\tilde{\delta}' \tilde{\phi}^{(q-r,r)} + \delta_1 \tilde{\phi}^{(q-r-1,r+1)} = 0 , \quad r = 1, \cdots, q - 1 ,$$

$$\tilde{\delta} \tilde{\phi}^{(0,q)} = 0 .$$

\footnote{We use the notation $h'$ for $|H'| = \sum_{i=2}^{n} h_i$.}
Solving these equations in turn, beginning from the first one, we obtain easily, using the triviality of the cohomology of $\delta_1$:
\[
\tilde{\phi}'(q,0) = \delta_1 \tilde{\psi}'(q-1,0),
\]
\[
\tilde{\phi}'(q-r,r) = \delta_1 \tilde{\psi}'(q-r-1,r) + \tilde{\delta}' \tilde{\psi}'(q-r,r-1), \quad r = 1, \ldots, q - 1,
\]
\[
\tilde{\phi}'(0,q) = \tilde{\delta}' \tilde{\psi}'(0,q-1).
\]
This result can be rewritten as
\[
\tilde{\phi}' = \tilde{\phi}' \tilde{\psi}^{q-1}, \quad \text{with} \quad \tilde{\psi}^{q-1} = \sum_{r=0}^{q-1} \tilde{\psi}'(q-1-r,r).
\]
We note that for $q = 0$ we have $\tilde{\phi}' = \tilde{\phi}'(0,0)$ and the solution is $\tilde{\phi}' = 0$. We have thus proven the triviality of the cohomology in the case 1.

**Case 2**: $h_1 \leq q < h'$. In this case the truncated form is given by
\[
\tilde{\phi}^q = \sum_{r=q-h_1}^{q} \tilde{\phi}'(q-r,r),
\]
and the cohomology condition (C.8) yields
\[
\tilde{\delta}' \tilde{\phi}'(h_1-r,q-h_1+r) + \delta_1 \tilde{\phi}'(h_1-r-1,q-h_1+r+1) = 0, \quad r = 0, \ldots, h_1,
\]
\[
\tilde{\delta}' \tilde{\phi}'(0,q) = 0.
\]
This time one has to begin with the last of these equations, and use the induction hypothesis according to which the cohomology of $\tilde{\delta}'$ is trivial when applied to partial truncated forms (C.6) which are not of maximal weights, i.e. such that $r < h'$. The solution reads
\[
\tilde{\phi}'(0,q) = \tilde{\delta}' \tilde{\psi}'(0,q-1),
\]
\[
\tilde{\phi}'(r,q-r) = \tilde{\delta}' \tilde{\psi}'(r,q-r-1) + \delta_1 \tilde{\psi}'(r-1,q-r), \quad r = 1, \ldots, h_1,
\]
which again may be written as in (C.10), showing the triviality of the cohomology in the case 2.

**Case 3**: $h' \leq q < |H|$. The truncated form reads
\[
\tilde{\phi}^q = \sum_{r=q-h_1}^{q-h'} \tilde{\phi}'(q-r,r),
\]
and the cohomology condition (C.8) yields
\[
\tilde{\delta}' \tilde{\phi}'(h_1-r,q-h_1+r) + \delta_1 \tilde{\phi}'(h_1-r-1,q-h_1+r+1) = 0, \quad r = 0, \ldots, h_1 + h' - q - 1.
\]
The situation is a bit more subtle. We begin from the equation (C.11) with $r = 0$, and use the result of Corollary 2 of Proposition B.1 – valid due to the triviality of the cohomology of both $\delta_1$ and $\tilde{\delta}'$ – from which we can write
\[
\tilde{\phi}'(h_1,q-h_1) = \tilde{\delta}' \tilde{\psi}'(h_1,q-h_1-1) + \delta_1 \tilde{\psi}'(h_1-1,q-h_1),
\]
\[
\tilde{\phi}'(h_1-1,q-h_1+1) = \tilde{\delta}' \tilde{\psi}'(h_1-1,q-h_1) + \delta_1 \tilde{\psi}'(h_1-2,q-h_1+1).
\]
Now substituting this result in \((C.11)\) for \(r = 1\) and using the triviality of the cohomology of \(\delta_1\), we get the first of the following equations – the one for \(r = 2\):

\[
\tilde{\phi}_r'(h_1 - r, q - h_1 + r) = \delta_1^{\prime} \tilde{\psi}_r'(h_1 - r, q - h_1 + r - 1) + \delta_1 \tilde{\psi}_r'(h_1 - r - 1, q - h_1 + r), \quad r = 2, \ldots, h_1 + h' - 1. \quad (C.13)
\]

The remaining ones, for \(r \geq 3\), are obtained in the usual way using the triviality of the cohomology of \(\delta_1\). The result \((C.13)\) can be rewritten as \((C.10)\), showing the triviality of the cohomology in the case 3.

**Case 4:** \(q = |H| = h_1 + h'\)  
This is the case of highest weight:

\[
\tilde{\phi}^{q} = \tilde{\phi}_r'(h_1, h') = \phi(h^1, \ldots, h^n),
\]

which satisfies identically the cohomology condition \((C.8)\). It may be the \(\delta'\)-variation of some truncated form \(\tilde{\phi}_r'|H|^{-1}\), or not. In the latter case it belongs to the cohomology of \(\delta'\).

Joining together the results of these four cases ends the proof of Proposition \(C.1\). \(\square\)

## D  Wess-Zumino gauge and covariant superfields

As shown in \([10]\) it is possible to fix algebraically the gauge degrees of freedom corresponding to the ghosts \(c_{I_1 \cdots I_n}(x)\) \((1 \leq n \leq N)\), through the conditions\(^\text{10}\)

\[
e_I(x) = 0, \quad e_{[I_1 \cdots I_n]}(x) = 0 \quad (1 \leq n \leq N). \quad (D.1)
\]

This defines the so-called Wess-Zumino (WZ) gauge, analogous to the one encountered in the supersymmetric Yang-Mills theories \([13]\). We are left with the usual gauge degree of freedom corresponding to the ghost \(c(x)\). The physical degrees of freedom are labeled by the covariant fields

\[
\left\{ F_a, a_{I_1 \cdots I_n}, e_{I_1 \cdots I_{n+1}}^{(M)}, D_a a_{I_1 \cdots I_n}, D_a e_{I_1 \cdots I_{n+1}}^{(M)} : n \geq 1 \right\}, \quad (D.2)
\]

where \(F_a\) and \(D_a\) are the Yang-Mills curvature and the covariant exterior derivative with respect to the connection \(a\), and \(e_{I_1 \cdots I_n}^{(M)}\) is the mixed symmetry tensor corresponding to the second Young tableau in the right-hand side of the figure \(D.1\) and defined by the expansion

\[\text{Figure D.1: Expansion (D.3) of the tensor } e_{I_1 I_2 \cdots I_n}\]

\(^{10}\)The field components of the superfields of the theory are defined by \((2.9-2.10)\).
The BRST transformations of the fields (D.2) are covariant:

\[ S\phi = -[c, \phi] \]  

(D.4)

The stability of the WZ-gauge choice requires a redefinition of the SUSY operators – acting on the fields (D.2) and \( a \):

\[ \tilde{Q}_I = Q_I + \delta(\lambda_I), \]  

(D.5)

where \( \delta(\lambda_I) \) is a supergauge transformation of field dependent parameters

\[ \lambda_{I1\ldots In} = \frac{1}{n!n} e^{(M)}_{I1\ldots In} \]  

(D.6)

equivalent to a superfield BRST transformation (2.12) with the ghost components \( c_{I1\ldots In} \) given by (D.6) and with \( c = 0 \). The superalgebra (2.1) now closes on gauge transformations

\[ [\tilde{Q}_I, \tilde{Q}_J] = -2\delta_{\text{gauge}}(e^{(M)}_{IJ}) \]  

(D.7)

doing field dependent parameters \( e^{(M)}_{IJ} \).

Let us now show that there is a bijection between the set of fields (D.2) and the following set of covariant superfields:

\[ \left\{ F_A, \Psi^{(A)}_{I1\ldots In}, \Phi^{(M)}_{I1\ldots In+1}, D_A\Psi^{(A)}_{I1\ldots In}, D_A\Phi^{(M)}_{I1\ldots In+1}; n \geq 1 \right\}. \]  

(D.8)

\( F_A \) and \( D_A \) are the Yang-Mills curvature and the covariant exterior derivative with respect to the superfield connection \( A \), and the remaining elements are defined from the supercurvature components (2.14) by

\[ \Psi^{(A)}_{I1\ldots In} = \Psi_{[I_1|I_2\ldots I_n]}, \]  

\[ \Phi^{(M)}_{I1\ldots In+1} = \frac{n}{n+1} \left( \Phi_{I1[I_2|I_3\ldots I_{n+1}]} + \Phi_{I2[I_1|I_3\ldots I_{n+1}]} \right) \]  

(D.9)

The bracket \([\cdots]\) means complete antisymmetrization in the indices, the bar | symbolizes covariant \( \theta \)-derivations:

\[ \Psi_{I1|I_2\ldots I_n} = D_I D_{I_2\ldots I_n} \Psi_{I}, \quad D_I X = \partial_I X + [E_I, X], \]  

and the mixed symmetry tensors \( \Phi^{(M)}_{I1\ldots In+1} \) belong to the expansion of the covariant \( \theta \)-derivatives \( \Phi_{I1I2|I_3\ldots I_{n+1}} \) in irreducible representations of the permutation group \( S_{n+1} \): they correspond to the Young diagram shown in the right-hand side of the figure D.2.

All the objects \( X \) in (D.8) are covariant, i.e.

\[ S X = -[C, X]. \]  

25
The bijection between the set (D.2) and the set (D.8) is simply given by the fact that the elements of the former are equal to the \( \theta = 0 \) components of the elements of the latter, provided the WZ-gauge conditions (D.1) are applied:

\[
\begin{pmatrix}
F_a, & a_{I_1\cdots I_n}, & e^{(M)}_{I_1\cdots I_{n+1}}, & D_a a_{I_1\cdots I_n}, & D_a e^{(M)}_{I_1\cdots I_{n+1}} \\
F_A, & \Psi^{(A)}_{I_1\cdots I_n}, & \Phi^{(M)}_{I_1\cdots I_{n+1}}, & D_A \Psi^{(A)}_{I_1\cdots I_n}, & D_A \Phi^{(M)}_{I_1\cdots I_{n+1}}
\end{pmatrix}
\bigg|_{\theta = 0, \text{WZ}}, \quad n \geq 1.
\]

This is obvious for \( F_A \). For \( \Psi^{(A)}_{I_1\cdots I_n} \), we observe that each \( \theta \)-derivative of \( \Psi_I \) brings in factors of \( \theta \)-derivatives \( E_{I_1\cdots I_k} \) or space-time covariant derivatives of them. However, only completely antisymmetrized derivatives \( E_{[I_1,I_2\cdots I_k]} \) may contribute as factors to the completely antisymmetric tensor \( \Psi^{(A)} \). Since these completely antisymmetrized derivatives vanish at \( \theta = 0 \) due to the WZ-gauge conditions, we are left with the simple \( \theta \)-derivatives of \( A \), which at \( \theta = 0 \) yield the fields \( a_{I_1\cdots I_n} \). The same conclusion holds for the terms \( D_A \Psi^{(A)}_{I_1\cdots I_n} \).

The argument is similar for the terms \( \Phi^{(M)}_{I_1\cdots I_{n+1}} \) (and \( D_A \Phi^{(M)}_{I_1\cdots I_{n+1}} \)): only factors of completely antisymmetrized derivatives of \( E_I \) may contribute to these mixed symmetry tensors, made from covariant \( \theta \)-derivatives of the symmetric tensor \( \Phi_{I_1I_2} \) and symbolized by the diagram shown in the right-hand side of the figure (D.2). And this same diagram defines the symmetry properties of \( e^{(M)}_{I_1\cdots I_{n+1}} \).
