Abstract

This paper presents a case study of using distributed word representations, word2vec in particular, for improving performance of Named Entity Recognition for the e-Commerce domain. We also demonstrate that distributed word representations trained on a smaller amount of in-domain data are more effective than word vectors trained on very large amount of out-of-domain data, and that their combination gives the best results.

1 Introduction

On-line commerce has gained a lot of popularity over the past decade. Large on-line C2C marketplaces like eBay, Alibaba, and Amazon feature a very large and long-tail inventory with millions of items (product offers) entered into the marketplace every day by a large variety of sellers.

To manage items effectively and provide the best user experience, it is critical for these marketplaces to structure their inventory into descriptive name-value pairs (called properties) and ensure that items of the same kind (digital cameras, for instance) are described using a unique set of properties (brand name, model number, zoom, resolution, etc.). This is important for recommendations in merchandising, providing faceted navigation, and assisting business intelligence applications.

While some sellers (generally large, professional retailers) provide rich, structured descriptions of their products (using schemas or global trade item numbers), the vast majority of sellers only provide unstructured natural language descriptions. In the latter case, one solution to the problem of structuring e-commerce inventory is to use techniques such as Named-Entity Recognition (NER) to extract properties from the textual description of the items. The scale at which on-line marketplaces operate makes it impractical to solve this problem manually. ¹

This paper focuses on NER, generally defined as the task of classifying elements of text into predefined categories (often referred to as entity types or entities). Entities usually include names of persons, organizations, locations, times, and quantities (CoNLL–2003 dataset), as well as nationalities or religious groups, products (vehicles, weapons, foods, etc.), and titles of books or songs (Ontonotes 5.0 dataset).

In the e-commerce domain, these entities are item properties such as brand name, color, material, clothing size, golf club type, makeup shade code, sun protection factor, etc. Another important specificity of the e-commerce domain with respect to NER is that the sentences are usually much shorter than in other applications and don’t exhibit the grammatical structure of natural language.

This paper investigates whether distributed word vectors benefit NER in the e-commerce domain. Distributed word representations based on neural networks from unlabeled text data have proven useful for many natural language tasks, including NER. In fact, Passos et al. (2014) reported results compa-

¹For instance, in late 2014, eBay.com reported 800 million available items at any given time and more than 25 million sellers. Alibaba.com reported 8.5 million sellers. Amazon.com has not disclosed similar information.
rable to state-of-the-art for the CoNLL 2003 NER
task using such representations. In this paper, we
evaluate distributed word vectors with a focus on us-
ing in–domain data for their training.

In the remainder of this paper, we first explain
the specificity of NER in the e-commerce domain
and describe the approach we use for performing the
 task. In Section 3, we describe our datasets. In Sec-
tion 4, we describe the setting of the experiments we
have conducted and discuss the results in Section 5.
Finally, we review related works in Section 6.

2 NER for e-Commerce

The e-commerce domain raises specific challenges
for NER. This section describes in detail the task,
and the methodology we have chosen to tackle it.

2.1 Description of the task

We consider the task of named entity recognition
(NER) on text from the e-commerce domain. The
text data associated with an e-commerce item usu-
ally consists of two parts: the title and the descrip-
tion. In the current work, we focus only on item
titles since item descriptions are often optional, vary
greatly from seller to seller and between market-
places, and are not shown on the search results page.
The item title is a short sentence usually consisting
of a sequence of approximately 10 to 35 nouns, ad-
jectives, and numbers. They rarely contain verbs,
pronouns, or determiners. The title is mandatory for
most marketplaces, as it is indexed by the search en-
gen and searched against by users of the website.
Snippets shown in search result pages are generated
from the titles of the items in the search result set.

Table 1 shows some examples of item titles (rows
1, 3, 5) from various online marketplaces. These
examples show that sellers use capitalization and
special characters as visual features in a manner
not necessarily consistent with conventional English
grammar rules. Besides their limited grammatical
structure and the lack of contextual information due
to their length, titles also contain typographical er-
rors and abbreviations. While many abbreviations
are standard in the e-commerce domain and used
across all marketplaces (such as “w/” for “with”,
“NIB” for “new in box”, “BNWT” for “brand new
with tag”, etc.), some are seller specific and are often
difficult to decipher.

Performing NER for e-commerce involves classi-
fying the various tokens in the title of an item into
property names (entities) relevant to that item. Ta-
ble 1 also shows the annotated entities (rows 2, 4, 6)
for each of the titles. Section 3 provide details about
the e-commerce categories, and the empirically de-
defined entities within each of those categories. Next,
we describe the approach that we use for NER.

2.2 Approach

Following current best practices, we approach NER
as a sequence labeling problem. We use linear–
chain Conditional Random Field (CRF) (Lafferty et
al., 2001) which has been shown to achieve the best
performance for many applications of NER (Suzuki
and Isozaki, 2008; Lin and Wu, 2009; Passos et
al., 2014), including NER for the e-commerce do-
main (Putthividhya and Hu, 2011).

We use a fairly standard set of lexical features
used in most NER systems, including character af-
fixes. Our features are detailed in Section 4.

In addition to the lexical features, modern NER
systems also attempt to leverage some form of vec-
tor representation of the syntactic and semantic
properties of the tokens. While discrete word rep-
resentations derived from word clusters have been
shown to be very beneficial to NER (Miller et al.,
2004; Lin and Wu, 2009; Ratinov and Roth, 2009;
Turian et al., 2010), more and more attention is be-
ing paid to distributed word representations since
the introduction of efficient algorithms to produce them
(Mikolov et al., 2013). Passos et al. (2014), for in-
stance, reported performance comparable to state-
of-the-art NER systems using a modified skip–gram
model trained to predict membership of words to a
domain specific lexicon.

To the best of our knowledge, all the results re-
ported so far for NER used distributed word vec-
tors trained from documents composed in standard,
mostly grammatical English (Collobert and Weston,
2008; Turian et al., 2010; Baroni et al., 2014; Passos
et al., 2014). However, it is clear that some phrases
in the e-commerce domain have a very different
meaning than in conventional English. For instance,
“adventure time,” “baby, the stars shine bright,”
and “miss me” are a few examples of e-commerce
brand names which occur rarely in Wikipedia. In
1: Apple iPhone 6 - 16GB - Space Grey (Unlocked) Smartphone
2: Cole Haan Men’s Carter Grand Cap Oxford
3: Womens CRISTINALOVE SHOULDER DRESS - Size XL - L@@K

Table 1: Examples of annotated titles for different e-commerce categories from various online marketplaces. Entity types are denoted by the single letters: “a”- “contract,” “b”– “brand name,” “c”– “color,” “d”– “dimension,” “g”– “gender,” “p”– “product name or number,” “t”– “type,” “s”– “size.”

In this paper, we investigate whether useful distributed representations can be learned from fairly unstructured, short, ungrammatical documents such as e-commerce titles and capture enough e-commerce semantics to benefit NER. We also study how they compare to distributed vectors trained from a non e-commerce corpus.

3 Data

To make discovering and browsing the inventory easy, most on-line marketplaces organize their inventory into a category structure similar to a topic hierarchy. eBay and Alibaba hierarchies comprise around 40 top level nodes, called categories, and more than 10,000 leaf nodes. The goods from different categories are usually very different in nature as exemplified by eBay categories such as “Antiques,” “Clothing, Shoes & Accessories,” and “Toys & Hobbies,” to name a few.

3.1 Data Selection

The models trained for our experiments focus on a subset of five popular categories, namely Cellphones (CELLPH), Cellphone Accessories (CELLACC), Men’s Shoes (MSHOES), Watches (WATCHES), and Women’s Clothing (WCLOTH). Our datasets consist of user-defined e-commerce item titles. Table 2 provides statistics about these titles. Titles were tokenized using CoreNLP (Manning et al., 2014).

3.2 Training and testing data

Training and testing data for CRF was produced by manually labeling data. Based on the labeling resources available, we sampled 2,000 titles for most categories. Splitting these samples resulted in the training and test splits shown in Table 3.
this does not scale well and makes the annotation task more difficult. Table 4 shows the set of entities used for each category and the distribution of entities over the individual tokens within each category.

3.4 Annotation Procedure

Titles in Table 3 were annotated by two language specialists. Annotators had access to the listing page of the item in question to use as a reference. This page typically includes some pictures as well as a description of the item which may provide information about a particular token and reduce the amount of research required to correctly label a token (e.g. an obscure brand name). The two annotators regrouped after tagging to resolve disagreements between the individually tagged data sets. Agreement scores between the annotators were calculated using unweighted Cohen’s Kappa with the following results: CELLPH: .92, CELLACC: .82, MSHOES: .78, WATCHES: .81, WCLOTH: .93. BIO encoding was not used for these datasets, but experimenting with it is important, and we plan do so in future work.

3.5 word2vec training data

For training the category–specific in–domain word vector representations, the set of tokenized titles referred to in Table 2 are used for the respective category. Section 4 provides details about the word2vec training process.

4 Experiments

We now present our experimental results for NER on e-commerce item titles. The goal of our work is not necessarily to present the best possible results for this task. Instead, our experiments are driven by the following two questions: (1) Are distributed word representations created from highly unstructured data (namely, e-commerce item titles) beneficial for the task of named entity recognition on the same kind of unstructured data? (2) How do distributed word vector representations created from out-of-domain (namely, non e-commerce data) compare with those created from in-domain data?

4.1 Training

We use the CRFsuite package (Okazaki, 2007) for our experiments. Following Turian et al. (2010), we use stochastic gradient descent (SGD) for our training, and allow negative state features and negative transition features. The \( l^2 \) regularization hyper–parameter \( (c^2 \) for CRFsuite) is tuned using a randomly chosen subset of 30% sentences (item titles) held out as the development set during training. The final model is retrained on the entire training set using the best value of \( c^2 \) (which varies depending on the feature configuration). The set of \( c^2 \) values we tried is \{0.001, 0.005, 0.01, 0.05, 0.1, 1, 2, 5, 10, 50, 100\}.

4.2 Baseline Features

Table 5 shows the features that we use for our baseline. We refer to this feature set by the name BASE in our results section.

We also experimented with larger window sizes (two and three) for all of the windowed features listed in Table 5, however, the performance degraded for larger window sizes. We believe this is due to the highly unstructured nature of text in the item titles.

4.3 Distributed Word Vector Features

We explored two different types of sources of text for the generation of distributed word representations for our task. First, we used word vectors trained by Baroni et al. (2014) — in particular, the “best predict vectors” made available by the authors. These are, for our purposes, vectors trained on out-of-domain text corpora. Results using features based on these word vectors are denoted by the name BASE+GEN. In our experiments, features based on word vectors are always added on top of

| feature | comment |
|---------|---------|
| \( w_0, w_{-1}, w_{+1} \) | current token, tokens in window of 1 |
| \( \langle w_{-2}, w_{-1}, (w_{+1}, w_{+2}) \) | left and right bigram |
| CLASS\((w_{-1}, w_0, w_{+1})\) | ALLCAPS, Initcap, UpperCamelCase, etc. |
| \( w_{0} \) | length of current token |
| RELPOS\((w_{0})\) | relative position in the item title |
| AFFIXES\((w_{-1}, w_0, w_{+1})\) | up to 3-character prefixes and suffixes |
| \( t_{-1} \) | tag of the previous token |

Table 5: Table shows the features that we use for our baseline.

\(^2\)http://clic.cimec.unitn.it/composes/semantic-vectors.html
Table 4: The entities targeted by our NER system and their distributions over total tokens for each category.

| Category | Tag |
|----------|-----|
| CELLPH   | Product Name 17.8%, Brand 11.3%, Dimension 7.4%, Color 5.2%, Contract 3.8%, Operating System 2.1%, Location 0.4%, no tag 52.0% |
| CELLACC  | Product Name 25.6%, Type 19.4%, Brand 7.3%, Feature 3.8%, Material 2.4%, Color 2.3%, Style 1.2%, Connectivity 1.1%, Pattern 0.6%, Battery Capacity 0.4%, Location 0.4%, Finish 0.3%, Fit 0.3%, Storage Capacity 0.3%, Storage Format 0.2%, Sports Team 0.2%, no tag 34.2% |
| MSHOES   | Product Line 28.2%, Brand 11.4%, Color 8.8%, Size 6.9%, Type 5.6%, Gender 3.9%, Purpose/Occasion/Activity 2.9%, Material 2.2%, Height 1.3%, Style 1.1%, Pattern 0.4%, no tag 27.3% |
| WATCHES  | Product Name 13.8%, Brand 9.3%, Type 7.4%, Feature 5.1%, Gender 4.7%, Material 4.0%, Color 3.1%, Movement 2.9%, Component 2.9%, Style/Purpose/Occasion 2.9%, Size 1.1%, Display Type 0.8%, Location 0.8%, Purity/Quality 0.3%, Shape 0.2%, Closure 0.1%, no tag 40.6% |
| WCLOTH   | Type 16.0%, Brand 8.3%, Size 7.3%, Color 4.0%, Material 3.8%, Purpose/Occasion/Activity 3.2%, Style 2.1, Pattern 1.5%, Location 0.8%, no tag 53.0% |

our baseline features (BASE). Second, we used word vectors trained on a large set of in-domain data for each of the five categories, namely e-commerce item titles for the respective categories. The word vectors for each category were trained separately, in order to provide the “purest” form of in–domain data. Results using features based on these word vectors are denoted by the name BASE+DOM. Additionally, we also conduct experiments using features based on both the in–domain as well as out–of–domain word vectors. Results using this combined set of word vector features are denoted by BASE+ALL.

Word vector features are computed for $w_0$, $w_{-1}$, and $w_{+1}$— that is, for the current token and its two surrounding tokens. Here too, we experimented with larger window sizes, but that resulted in a lower overall performance.

4.4 word2vec

Both the out–of–domain and the in–domain word vectors that we train are trained using the word2vec toolkit$^3$ (Mikolov et al., 2013). Details of how the out–of–domain word vectors were trained is provided by Baroni et al. (2014) — their 400–dimensional word vectors were trained on approximately 2.8 billion tokens using word2vec’s continuous bag–of–words (cbow) representation, with a window size of five.

Initially, we experimented with several parameter choices for training our word2vec models. In particular, we tried the following grid of values: representation: skip–gram, continuous bag–of–words (cbow); context window size: $\{2, 5\}$, downsampling parameter: $\{1e-3, 1e-4, 1e-5\}$; hierarchical softmax: $\{off, on\}$; # of negative samples: $\{5, 10\}$; word frequency cutoff: $\{10, 50\}$; and word vector dimensionality: $\{50, 100, 200, 300, 400, 500\}$. Based on this parameter sweep, we found that the following parameters worked best overall for our task: representation: skip–gram, context window size: 2, down–sampling parameter: $1e-3$, hierarchical softmax: off, # negative samples: 10, word frequency cutoff: 50. These are the settings we use for all the results reported in this paper. As for the word vector dimensionality, we tuned it based on our validation set (similar to the $c2$ parameter for CRFsuite), using the following set of values: $\{50, 100, 200, 300, 400, 500\}$). In our results we will report the best word vector dimensionality when features based on in–domain word vectors are used.

The skip–gram representation worked better in our experiments for capturing semantics of the word co–occurrences in the item titles. This is consistent with the comparative analysis published by Mikolov et al. (2013) between skip–gram and cbow models — the cbow models were found to be better for syntactic tasks while the skip–gram models were better for semantic tasks. A narrower context window is better for our highly unstructured data.

5 Results and Discussion

Table 6 shows our complete set of results. We report the weighted token–level precision, recall, and F1 score for all our experiments: $F_{\text{weighted}} =$

---

$^3$https://code.google.com/p/word2vec
Table 6: Table shows the full set of results (weighted precision, recall, and F1) for each of the five e-Commerce categories we experiment with. The last column shows the best (tuned) word2vec dimensionality for the in-domain word vectors.

\[ \sum_{t \in \text{tags}} p(t) F1(t), \] where \( p(t) \) is the relative frequency of tag \( t \) in the test set and \( F1(t) \) is the F1 score for tag \( t \).

Several trends are clear from the results. First, the combined feature set based on in-domain and out-of-domain word vectors (BASE+ALL) gives the best performance for all categories, with a boost of 2+ percentage points over BASE for all categories except CELLPH. Second, most of the improvement over the baseline (BASE) is achieved by the in-domain word vector features (BASE+DOM). Except for the WATCHES category, the out-of-domain word vector features by themselves are less useful compared to the in-domain vectors. This is not entirely surprising. However, it is worth noting for a couple of reasons: (1) The in-domain data we have, as mentioned earlier, is highly unstructured, and it is not obvious that word vectors trained on such data will be meaningful, let alone useful in a quantitative evaluation like the one we have presented. (2) The in-domain data that we use for word vector training is, in most cases, significantly smaller than the dataset used for training the out-of-domain word vectors. While we directly use the word vectors from Baroni et al. (2014) as our out-of-domain vectors (since they have been shown to perform well across a range of semantic relatedness tasks), in the future it might be worth tuning the out-of-domain word vectors specifically for our task.

In order to gain an understanding of where the distributed word representations are useful, we performed an error analysis on the predictions from our various models. Table 7 shows several different item titles where our trained models differed. The table shows, for example, that the BASE+DOM model is able to identify “Movistar” as a brand correctly, while the BASE model is not. This is interesting because “Movistar” does not appear in our training data at all. However, it does have a representation in our word2vec model, and thus the BASE+DOM model is able to correctly tag it. The BASE+DOM model also correctly tags both tokens in “Red Pocket” as a brand, unlike the BASE+GEN model, which tags them as color and contract incorrectly. This shows that the in-domain semantic representation for the token “Red” is more useful compared to its out-of-domain representation. Finally, there are also cases where the out-of-domain semantic representation adds value: “TANGERINE”, for example, is correctly predicted as a color by BASE+ALL, but not by BASE+DOM because it is not present in our in-domain vectors.

6 Related Work

6.1 Word representations

The problem of modeling the meaning of words in text has been approached in various ways including distributional semantics (see Turney and Pantel (2010), Erk (2012) for surveys), word clustering (Brown et al., 1992; Lin and Wu, 2009), and, more recently, distributed representations (Mnih and Hinton, 2007; Collobert and Weston, 2008).

While word clusters and distributional approaches have been shown to be very effective for NER applications (Miller et al., 2004; Lin and Wu, 2009; Ratinov and Roth, 2009; Turian et al., 2010; Dhillon et al., 2011), direct applications of distributed representations to NER systems did not show benefit over Brown clusters (Turian et al., 2010). However, Passos et al. (2014) recently reported performance
comparable to state-of-the-art NER systems using a modified skip-gram model trained to predict membership of words to a domain specific lexicon.

### 6.2 E-Commerce

E-commerce has recently garnered attention in the natural language processing research community.

Ghani et al. (2006) and Putthividhya and Hu (2011) also address the problem of structuring items in the e-commerce domain through NER and present experimental results on data similar to ours, but do not leverage word vector representations. Mauge et al. (2012) presents an unsupervised approach for identifying attribute names and values from unstructured natural language listings seen in e-commerce sites. Finally, unrelated to NER, Shen et al. (2012) proposed a method for hierarchical classification of product offers which they validated on eBay data.

### 7 Conclusions

Distributed word representations have been used successfully for improving performance on several natural language processing tasks in the recent past, including the task of named entity recognition (NER). Much of the work, however, has focused on learning these word representations from corpora that consist of relatively well-formed, grammatical language. Moreover, the NER tasks that used these word representations were also based on similar well-formed language. In this work we explore distributed word representations based on e-commerce domain item titles, which are highly unstructured in nature. We also evaluate our constructed word vectors on the task of NER for these item titles.

Our experiments show the following: (1) It is possible to learn useful (as evaluated quantitatively on an NER task) distributed word representations based on unstructured e-commerce item title data. (2) The word representations that we train on a relatively small amount of in-domain data are, in general, more useful than word representations trained on very large out-of-domain data. (3) The combination of in-domain and out-of-domain word representations gives the best result, adding domain knowledge where necessary, while also using background general knowledge from out-of-domain representations.

Based on our experiments, there are a couple of interesting questions that may be considered for future research. First, we use the most straightforward way of combining in-domain and out-of-domain knowledge – training these word representations separately and using features based on both of them. Whether it is possible to learn better word representations by considering in-domain and out-of-domain data simultaneously at training time is an open question. Second, in our task formulation, the multiple e-commerce categories were trained separately even though they share some semantic tags. This can be improved upon in the future by considering approaches to multi-task learning.
