A Fast Computational Optimization for Control and Trajectory Planning for Obstacle Avoidance between Polytopes

Akshay Thirugnanam*, Jun Zeng*, and Koushil Sreenath

Abstract—Obstacle avoidance between polytopes is a challenging topic for optimal control and optimization-based trajectory planning problems. Existing work either solves this problem through mixed-integer optimization, relying on simplification of system dynamics, or through model predictive control with dual variables using distance constraints, requiring long horizons for obstacle avoidance. In either case, the solution can only be applied as an offline planning algorithm. In this paper, we exploit the property that a smaller horizon is sufficient for obstacle avoidance by using discrete-time control barrier function (DCBF) constraints and we propose a novel optimization formulation with dual variables based on DCBFs to generate a collision-free dynamically-feasible trajectory. The proposed optimization formulation has lower computational complexity compared to existing work and can be used as a fast online algorithm for control and planning for general nonlinear dynamical systems. We validate our algorithm on different robot shapes using numerical simulations with a kinematic bicycle model, resulting in successful navigation through maze environments with polytopic obstacles.

I. INTRODUCTION

Obstacle avoidance in optimization-based control and trajectory planning has received significant attention in the robotics community. When a tight-fitting obstacle avoidance motion is expected, the robot and the obstacles need to be considered as polyhedral. In this paper, we propose an optimization formulation to consider obstacle avoidance between polytopes using discrete-time control barrier function (DCBF) constraints with dual variables. The proposed formulation is shown to be a computationally fast algorithm that can serve as a local planner to generate dynamically-feasible and collision-free trajectories, or even directly as a safety-critical controller for general dynamical systems.

A. Related Work

1) Graph Search-based and Sampling-based Approaches: Motion planning techniques in real-world applications often consider high-level path planning and low-level control synthesis, given safety requirements and dynamical constraints. Graph search-based and sampling-based approaches such as PRM [1], A* [2], RRT* [3] have been explored, and many variant approaches have also been proposed based on them, which could be applied as efficient strategies for high-dimensional kinematic planning. However, generally, these algorithms assume that a low-level controller exists, and is able to track kinematically feasible trajectories in real time. This leads to trajectories that are dynamically infeasible and results in large tracking errors on dynamical systems. Other approaches such as kinodynamic RRT* [4], LQR-RRT* [5] try to bridge the gap between path planning and control synthesis by finding appropriate steering inputs to go between two vertices in the sampling graph. But these approaches cannot do dynamic collision checking with respect to the exact nonlinear dynamics of the robot. For general dynamical systems, we still need to locally generate a dynamically feasible and collision-free trajectory.

2) Optimization-based Control and Trajectory Planning: We now narrow down our discussion to optimization-based approaches for generating collision-free trajectories. The existing methods in this sub-area can be classified under two categories: those that generate obstacle avoidance behavior with additional cost terms, and those that apply constraints to achieve similar behavior. Additional cost terms were first introduced under the philosophy of potential fields [6], and were later generalized to be named as “barrier function” [7]. This approach has been applied to solve optimal control and trajectory generation problems with broad applications [8]–[12]. Other methods consider the obstacle avoidance criteria
as constraints in the optimization problem. An example of such a constraint is the distance constraint, enforced using inequality constraints on the distance function between the robot and obstacles, where the robots and the obstacles are usually approximated as points [13], lines [14], paraboloids [15], ellipsoids [16], or hyper-spheres [17]. The distance functions for these shapes have analytical expressions and are differentiable so that nonlinear optimization (NLP) solvers can easily compute the gradients.

3) Obstacle Avoidance between Polytopes: When a tight-fitting obstacle avoidance motion is expected, the above over-approximations of the shape of the robot can lead to deadlock maneuvers, shown in Fig. 1. A tight polytopic approximation of the shape of the robot enables obstacle avoidance maneuvers that are less conservative, see [18]. However, the distance function between two polytopes is implicit and not analytic [19], and requires a large amount of numerical computation [20], [21]. Moreover, this distance function between polytopes is also non-differentiable with respect to the robot’s configuration, which makes it hard to be treated as a constraint directly for a nonlinear programming problem. For collision avoidance between two polytopes, mixed-integer programming [19], [22], [23] and applies well for linear systems but cannot be deployed as a real-time controller or trajectory planner for general nonlinear systems due to the added complexity from integer variables [24]. To handle the non-differentiability of the distance function between two polytopes, a duality-based approach [25] is introduced to reformulate constraints as a set of smooth non-convex ones. However, obstacle avoidance behavior with this method can only be achieved with a relatively long horizon and needs to be solved offline for nonlinear systems, shown in various robot platforms [26]-[29]. Recently, a dual optimization formulation [30] was introduced to construct a differentiable control barrier function (CBF) [31] for polytopes, but it only optimizes one-step control input and is only applicable for continuous-time affine systems with a relative-degree of one. This formulation could also run into a deadlock or general high relative-degree systems.

4) Obstacle Avoidance with DCBFs: To resolve the problems mentioned above, it’s required to propose a computationally fast multi-step optimization formulation for systems with nonlinear discrete-time dynamics. Recently, it has been shown that considering discrete-time control barrier function (DCBF) constraints instead of distance constraints can handle this challenge, where DCBF constraints can regulate the obstacle avoidance behavior with a smaller horizon and prevent local deadlock for trajectory generation, see [32]. The control and planning problems with one-step [33] or multi-step [32] optimization using DCBF constraints have been studied, and various applications on different platforms, including car racing [17], autonomous vehicles [34], and bipedal robots [35] have validated this approach. In the work mentioned above, the robots and the obstacles are only considered as points or hyper-spheres, while obstacle avoidance constraint between polytopes is still an unsolved problem. This motivates us to propose an optimization formulation using DCBF for obstacle avoidance between polytopes.

B. Contributions

The contributions of our paper are as follows:

- We formulate the dual form of the obstacle avoidance constraint between polytopes as DCBF constraints for safety. This proposed DCBF constraints are incorporated into an NMPC formulation which enables fast online computation for control and planning for general nonlinear dynamical systems.

- The proposed NMPC-DCBF formulation for polytopes are validated numerically. Different convex and non-convex shaped robots are shown to be able to navigate with tight maneuvers through maze environments with polytopic obstacles using fast real-time control and trajectory generation.

II. BACKGROUND

In this section, we present a brief background on optimization formulations using discrete-time control barrier functions and obstacle avoidance between polytopic sets.

A. Optimization Formulation using DCBFs

Consider a discrete-time dynamical system with states $x \in \mathcal{X} \subset \mathbb{R}^n$ and inputs $u \in \mathcal{U} \subset \mathbb{R}^m$, as

$$x_{k+1} = f(x_k, u_k),$$  \hspace{1cm} (1)

where $x_k := x(k)$, $u_k := u(k)$, $k \in \mathbb{Z}^+$, $\mathcal{U}$ is a compact set and $f$ is continuous.

1) Discrete-time CBFs: Obstacle avoidance for safety for this dynamical system is defined in terms of invariance of its trajectories with respect to a connected set. In other words, if the dynamical system (1) is safe with respect to a set $\mathcal{S} \subset \mathcal{X}$, then any trajectory starting inside $\mathcal{S}$ remains inside $\mathcal{S}$. The set $\mathcal{S}$ is defined as the 0-superlevel set of a continuous function $h : \mathcal{X} \rightarrow \mathbb{R}$ as:

$$\mathcal{S} := \{x \in \mathcal{X} \subset \mathbb{R}^n : h(x) \geq 0\}. \hspace{1cm} (2)$$

We refer to $\mathcal{S}$ as the safe set and it represents the region outside the obstacle. $h$ is defined as a discrete-time control barrier function (DCBF) if $\forall \ x \in \mathcal{S}$, $\exists \ u \in \mathcal{U}$ such that

$$h(f(x, u)) \geq \gamma(x)h(x), \quad 0 \leq \gamma(x) < 1,$$  \hspace{1cm} (3)

Let $\gamma_k := \gamma(x_k)$. Satisfying (3) implies $h(x_{k+1}) \geq \gamma_k h(x_k)$, i.e. the lower bound of the DCBF decreases exponentially with the decay rate $\gamma_k$ [33]. Given a choice of $\gamma(x)$, we denote $\mathcal{K}(x)$ as

$$\mathcal{K}(x) := \{u \in \mathcal{U} : h(f(x, u)) - \gamma(x)h(x) \geq 0\}. \hspace{1cm} (4)$$

Then, if $x_0 \in \mathcal{S}$ and $u_k \in \mathcal{K}(x_k)$, then $x_k \in \mathcal{S}$ for $\forall \ k \in \mathbb{Z}^+$, i.e. the resulting trajectory is safe [33].

Given a valid DCBF $h$ [31], imposing DCBF constraint (3) in an optimization problem could guarantee system safety, i.e., collision-free trajectories. If $\gamma(x)$ is close to 1, the system converges to $\partial \mathcal{S}$ slowly but can easily become infeasible. On the other hand, if $\gamma(x)$ is close to 0, the constraint (3) is feasible in a larger domain but can approach $\partial \mathcal{S}$ quickly.
and become unsafe. The later proposed formulation in [32] introduces a relaxing form of DCBF constraint as follows,

\[ h(f(x, u)) \geq \omega(x) \gamma(x) h(x), \quad 0 \leq \gamma(x) < 1. \]  

(5)

where the relaxing variable \( \omega \) resolves the tradeoff between feasibility and safety and is optimized with other variables inside an optimization formulation.

When one-step control input is optimized [33], it could lead to a deadlock situation such that the robot is safe but unable to track the reference command. A nonlinear model predictive control formulation [17] can overcome these problems, shown as follows,

**NMPC-DCBF [17]:**

\[
\begin{align*}
\text{min} \quad & p(x_{t+N|t}) + \sum_{k=0}^{N-1} q(x_{t+k|t}, u_{t+k|t}) + \psi(\omega_k) \\
\text{s.t.} \quad & x_{t|t} = x_t, \\
& x_{t+k+1|t} = f(x_{t+k|t}, u_{t+k|t}), \quad k=0, \ldots, N-1 \\
& u_{t+k|t} \in \mathcal{U}, \quad x_{t+k|t} \in \mathcal{X}, \quad k=0, \ldots, N-1 \\
& h(x_{t+k+1|t}) \geq \omega_k \gamma_k h(x_{t+k|t}), \quad \omega_k \geq 0 \\
& \text{for} \quad k=0, \ldots, \text{N_{CBF}}-1
\end{align*}
\]

(6)

where \( x_{t+k|t} \) and \( u_{t+k|t} \) denote the predicted state and input at time \( t+k \) evaluated at the current time \( t \). \( N \) and \( \text{N_{CBF}} \leq N \) denote the prediction and safety horizons respectively, which allows us to control the optimization computation complexity, and \( U = [u_{t|t}^T, \ldots, u_{t+N-1|t}^T]^T \) and \( \Omega = [\omega_0, \ldots, \omega_{\text{N_{CBF}}-1}] \) are the joint input and relaxation variables respectively. \( p(\cdot) \) and \( q(\cdot, \cdot) \) are the terminal and stage costs respectively, and \( \psi \) is the penalty function for the relaxation variable.

The optimization formulation (6) can be regarded as a control problem with \( U^* = [u_{t|t}^T, \ldots, u_{t+N-1|t}^T]^T \) as the optimized control inputs, as well as a trajectory planning problem with \( X^* = [x_{t|t}^T, \ldots, x_{t+N|t}^T]^T \) as the optimized trajectory. From the joint optimal input vector \( U^* \) the first input \( u_{t|t}^* \) is applied at time \( t \in \mathbb{Z}^+ \), and the optimization (6) is solved again at time \( t+1 \) with \( x_{t+1} \).

**B. Obstacle Avoidance between Polytopic Sets**

In this work, we assume that there are \( \text{N_O} \) static obstacles together with a single controlled robot. We further assume that the geometry of all the obstacles and the robot can be over-approximated with a union of convex polytopes, which is defined as a bounded polyhedron.

Let the state of the robot be \( x \in \mathbb{R}^n \) with its discrete-time dynamics as defined in (1) and the geometry of the robot and obstacles be in a \( l \)-dimensional space. We denote the geometry of \( i \)-th static obstacle and the dynamic robot at some state \( x \in \mathcal{X} \) by the polytopes:

\[
\begin{align*}
\mathcal{O}_i := \{ y \in \mathbb{R} : A^O_i y \leq b^O_i \}, \\
\mathcal{R}(x) := \{ y \in \mathbb{R}^l : A^R(x) y \leq b^R(x) \},
\end{align*}
\]

(7)

respectively, where \( y^O_i \in \mathbb{R}^{s^O_i}, i \in \{1, \ldots, \text{N_O} \} \) and \( b^R(x) \in \mathbb{R}^{s^R} \), where \( A^R, b^R \) are continuous. Inequalities on vectors are enforced element-wise. We assume that \( \mathcal{O}_i, i \in \{1, \ldots, \text{N_O} \} \) and \( \mathcal{R}(x) \) are bounded and non-empty. \( s^O_i, s^R \) represent the number of facets of polytopic sets for the \( i \)-th obstacle and the robot, respectively.

Then \( \mathcal{O}_i, \forall i \in \{1, \ldots, \text{N_O} \} \), and \( \mathcal{R}(x), \forall x \in \mathcal{X} \), are non-empty, convex, and compact sets, and the minimum distance between any pair \( (\mathcal{O}_i, \mathcal{R}(x)) \) is well-defined. The minimum distance is 0 if and only if \( \mathcal{O}_i \) and \( \mathcal{R}(x) \) intersect. The square of the minimum distance between \( \mathcal{O}_i \) and \( \mathcal{R}(x) \), denoted by \( h_i(x) \), can be computed using a QP as follows:

\[
\begin{align*}
h_i(x) &= \min_{(y^O_i, y^R) \in \mathbb{R}^{s^O_i}} \| y^O_i - y^R \|_2^2 \\
\text{s.t.} \quad & A^O_i y^O_i \leq b^O_i, \quad A^R(x) y^R \leq b^R(x),
\end{align*}
\]

(8a)

(8b)

where (8) is a convex optimization problem. To ensure safe motion of the robot, we enforce DCBF constraints [5] pairwise between each robot-obstacle pair. Then, the safe set corresponding to the pair \( (\mathcal{O}_i, \mathcal{R}) \) is defined as:

\[
S_i := \{ x \in \mathbb{R}^n : h_i(x) > 0 \}^c,
\]

(9)

where \( (-)^c \) denotes the closure of a set. Enforcing DCBF constraint for each \( h_i \) ensures that the state remains in \( S_i \) for all \( i \), and thus the state remains in \( S := \bigcap_{i=1}^{\text{N_O}} S_i \). Note that, due to the relaxation variable \( \omega \), enforcing multiple DCBF constraints for each \( h_i \) is equivalent to enforcing a single DCBF constraint on \( h(x) := \min_i h_i(x) \). Thus, we focus on how to enforce DCBF constraint for a given pair \( (\mathcal{O}_i, \mathcal{R}) \).

However, [3] requires computation of \( h_i(f(x, u)) \) via (6), which can only be solved numerically. This results in an optimization formulation with non-differentiable implicit constraints, which results in a significant increase in computation time. In the following section we derive explicit differentiable constraints which guarantee that the DCBF constraint is satisfied without affecting the feasible set of safe inputs \( K(x) \forall x \in \mathcal{X} \).

**III. OPTIMIZATION WITH DUAL DCBF CONSTRAINTS**

In this section, we derive the duality-based optimization which allows to generate obstacle avoidance maneuvers for the controlled robot in tight environments with obstacles.

**A. Dual Optimization Problem**

Corresponding to the minimization problem (8), we can define a dual problem. The dual problem is always a convex optimization problem, and a maximization problem if the original primal problem is a minimization one. The dual formulation of (8) can be explicitly computed as [36, Chap. 8]:

\[
\begin{align*}
g_i(x) &= \max_{(\lambda_i^O, \lambda_i^R)} -\lambda_i^O b^O_i - \lambda_i^R b^R(x) \\
\text{s.t.} \quad & \lambda_i^O A^O_i + \lambda_i^R A^R(x) = 0, \\
& \| \lambda_i^O A^O_i \|_2 \leq 1, \quad \lambda_i^O \geq 0, \quad \lambda_i^R \geq 0.
\end{align*}
\]

(10a)

(10b)

(10c)

Here \( \lambda_i^O, A^O_i \) represents the normal vector of the plane of maximum separation between the polytopes.
Let the idea in Sec. III-B by enforcing a constraint stronger than (3) which does not require explicit computation of $h_i(x)$. The dual formulation of (8), (10) can be used to achieve this. Let $\bar{g}_i(x, \lambda^{O_i}, \lambda^R) = -\lambda^{O_i}b^{O_i} - \lambda^R b^R(x) \leq h_i(x)$.

Then, at time $k$, we can enforce the stronger constraint

$$ -\lambda^{O_i}b^{O_i} - \lambda^R b^R(f(x_k, u)) \geq \gamma_k h_i(x_k) $$

(13)

which, using (12), implies

$$ h_i(f(x_k, u)) \geq \gamma_k h_i(x_k), $$

(14)

as required. Hence, the DCBF constraint can be enforced by (13) subject to $f(x_k, u)$, $\lambda^{O_i}$, $\lambda^R$ being feasible, i.e. the following set of inequalities should be satisfied

$$ -\lambda^{O_i}b^{O_i} - \lambda^R b^R(f(x_k, u)) \geq \gamma_k h_i(x_k), $$

(15a)

$$ \lambda^{O_i} A^{O_i} + \lambda^R A^R(f(x_k, u)) = 0, $$

(15b)

$$ \|\lambda^{O_i} A^{O_i}\|_2 \leq 1, \lambda^{O_i} \geq 0, \lambda^R \geq 0. $$

(15c)

By the Strong Duality Theorem [11], $\lambda^{O_i, *}, \lambda^R$ satisfying (10b)-(10c) such that for all $x \in \mathcal{X}$,

$$ \bar{g}_i(x, \lambda^{O_i, *}, \lambda^R) = -\lambda^{O_i, *}b^{O_i} - \lambda^R b^R(x) = h_i(x). $$

(16)

This means that for any fixed $x \in \mathcal{X}$, the input $u$ satisfies the DCBF constraint [4] with the implicit definition of $h_i$ if and only if the tuple $(u, \lambda^{O_i, *}, \lambda^R)$ satisfies (13). So, the feasible set of inputs is not reduced at any $x \in \mathcal{X}$.

C. Optimization Formulation

We adopt the philosophy of NMPC-DCBF method to enforce safety constraints between polytopes, as shown in Sec. III-B and construct a multi-step optimization formulation. For simplicity of notation, we drop the explicit dependence of $h_i(x_t+k|i)$ on $x_t$ and $[u^T_{t+1}, ..., u^T_{t+k-1}]^T$. Since $h_i(x_t+k|i)$ is also not explicitly known at time $t$, to impose DCBF constraints along the horizon, we extend the idea in Sec. III-B by enforcing a constraint stronger than $h_i(x_{t+k+1|i}) \geq \gamma_k h_i(x_t+k|i)$ which does not rely on computations of $h_i(x_{t+k+1|i})$ and $h_i(x_t+k+1|i)$ via (5).

The primal optimization problem [3] provides an upper bound to $h_i(x)$, which can be used in the stronger DCBF constraints. Let $(y^{O_i}, y^R)$ be any feasible solution of (3).

Since (3) is a minimization problem and its solution is well-defined for all $x \in \mathcal{X}$,

$$ h_i(x, y^{O_i}, y^R) := \|y^{O_i} - y^R\|_2^2 \geq h_i(x). $$

(17)

Then at time $t$, we can enforce

$$ -\lambda^{O_i}b^{O_i} - \lambda^R b^R(x_{t+k+1|i}) \geq \gamma_k \|y^{O_i} - y^R\|_2^2 $$

(18)

which, using (12) and (17), implies

$$ h_i(x_{t+k+1|i}) \geq -\lambda^{O_i}b^{O_i} - \lambda^R b^R(x_{t+k+1|i}) \geq \gamma_k \|y^{O_i} - y^R\|_2^2 \geq \gamma_k h_i(x_t+k|i), $$

(19)

as required. Additionally, we can introduce the relaxation variables without affecting the analysis in this section.

Then at time $t$, we first calculate $h_i(x_t|i)$ and the optimal solutions $(y_t^{O_i}, y_t^{R})$ explicitly using $x_t$ and (3), hence the NMPC-DCBF formulation for polytopes is shown as follows:

NMPC-DCBF for Polytopes:

$$ \text{min} \ p(x_{t+N|t}) + \sum_{k=0}^{N-1} q(x_{t+k|t}, u_{t+k|t}) + \psi(\omega_k) $$

(20a)

s.t. $x_{t|t} = x_t$, $y_t^{O_i} = y_t^{O_i,*}$, $y_t^{R} = y_t^{R,*}$

$$ x_{t+k+1|t} = f(x_{t+k|t}, u_{t+k|t}), \ k=0, ..., N-1 $$

(20c)

$$ u_{t+k|t} \in U, \ x_{t+k|t} \in \mathcal{X}, \ k=0, ..., N-1 $$

(20d)

$$ -\lambda^{O_i}b^{O_i} - \lambda^R b^R(x_{t+k+1|t}) \geq \gamma_k \|y^{O_i} - y^R\|_2^2, $$

(20e)

$$ \lambda^{O_i} A^{O_i} + \lambda^R A^R(x_{t+k|t}) = 0, \|\lambda^{O_i} A^{O_i}\|_2 \leq 1, $$

(20f)

$$ \lambda^{O_i} \geq 0, \lambda^R \geq 0, $$

(20g)

$$ \lambda^{O_i,k} \geq 0, \lambda^{R,k} \geq 0, \omega_k \geq 0, $$

(20h)

The subscripts of $\lambda^{O_i}, \lambda^R, y^{O_i}, y^R$ denote the time, (20e) is the DCBF constraint between polytopes, (20f) is the primal feasibility condition, and (20g)-(20h) are the dual feasibility conditions.

The initial conditions, system dynamics, constraints, and input and state constraints are represented by (20b), (20c), and (20d) respectively. This NMPC-DCBF formulation (20) corresponds to enforcing safety constraints only between the pair $(\mathcal{O}_i, \mathcal{R})$ of polytopes. To enforce DCBF constraints between every pair of robot and obstacle, we introduce corresponding dual and primal variables and enforce the constraints (20f)-(20h) for each pair.

D. Complexity and Performance

1) Exponential DCBF Constraint: To reduce complexity of the NMPC-DCBF shown in (20), we can modify the DCBF constraint $h_i(x_{t+k+1|i}) \geq \gamma_k h_i(x_{t+k|i})$ by enforcing the following exponential DCBF constraints:

$$ h(x_{t+k|i}) \geq \omega_k (\Pi_{j=0}^{k} \gamma_j) h(x_{t|t}). $$

(21)
The DCBF constraint (21) only contains $h(x_{t|t})$ in the RHS for all $k$, which can be explicitly computed at each time step using $x_t = x_{t|t}$. This leads to modifying (20e) as follows,

$$-\lambda_k^b b^b - \lambda_k^R b^R(x_{t+1|t}) \geq \omega_k(\Pi_{j=0}^k \gamma_j) h_i(x_{t|t})$$

Such a formulation speeds up the computational time as only $h(x_{t|t})$ is needed to be calculated at each time $t$. This change affects neither the feasibility nor the safety of the system.

2) Horizon Length Selection: Compared with distance constraints, DCBF constraints allow effective obstacle avoidance behavior with smaller horizon length. Our NMPC-DCBF does not require the obstacle avoidance horizon length $N_{\text{CBF}}$ equals to $N$, which additionally optimizes the complexity [32]. Additionally, maneuvers such as deceleration for obstacle avoidance or reversing motion for deadlock avoidance are motion primitives that only require a small horizon in the MPC formulation. To sum up, DCBF constraints with dual variables enable the fast optimization for obstacle avoidance between polytopes.

IV. Numerical Results

In this section, we consider an autonomous navigation problem. We model the controlled robot with different shapes, including triangle, rectangle, pentagon and L-shape. The proposed optimization-based planning algorithm allows us to successfully generate dynamically-feasible collision-free trajectories even in tight maze environments, shown in Fig. 2. Animation of the navigation problems can be found in the video attachment.

1) Environment: The tight maze environments is described by a combination of multiple convex obstacles, including shapes like triangle, rectangle, pentagon, etc. The controlled robot is also modeled with different shapes,
including triangle, rectangle, pentagon and L-shape, whose orientation is determined by the yaw angle. The L-shape is non-convex, but can be represented by two convex polytopes. The dimensions for each robot shape are mentioned in Fig. 2.

2) System Dynamics: The controlled robot is described by the kinematic bicycle model, which is typical for testing trajectory planning algorithm in tight environment. The continuous-time dynamics of the robot is given as follows, 
\[ \dot{c}_x = v \cos(\phi), \quad \dot{c}_y = v \sin(\phi), \quad \dot{v} = a, \quad \phi = \frac{v \tan \delta}{l}, \]  
where system states are \( c_x, c_y, v, \phi \) with \( c_x, c_y \) as the center of rear axes, \( \phi \) as yaw angle and \( v \) as the velocity, and \( a = (a, \delta) \) are inputs with steering angle \( \delta \) and acceleration \( a, l \) is the wheel base of the robot. The steering angle and acceleration are limited between \( \pm 0.5r \text{ad} \) and \( \pm 1m/s^2 \).

3) Global Planning: The global path from the starting position to the goal is generated using the A* algorithm. The 2-D space is sub-divided into grids and obstacle collisions checks are performed at each grid point during the algorithm. A safety margin, which is smaller than at least one dimension of the robot, is used for the collision checks. Finally, the generated optimal path is reduced to fewer waypoints using line-of-sight reductions, similar to the \( \theta^* \) algorithm [37]. The generated global path is not dynamically feasible, and is only safe at the node points.

4) Local Trajectory Generation: The local trajectory planning algorithm in tight environment. The continuous-time dynamics of the robot is given as follows, 
\[ \dot{x} = v \cos(\phi), \quad \dot{y} = v \sin(\phi), \quad \dot{v} = a, \quad \phi = \frac{v \tan \delta}{l}, \]  
where system states are \( x, y, v, \phi \) with \( x, y \) as the center of rear axes, \( v \) as yaw angle and \( v \) as the velocity, and \( a = (a, \delta) \) are inputs with steering angle \( \delta \) and acceleration \( a, l \) is the wheel base of the robot. The steering angle and acceleration are limited between \( \pm 0.5r \text{ad} \) and \( \pm 1m/s^2 \).

5) Warm Start: The NMPC-DCBF formulation is a non-convex optimization, and hence computationally challenging to solve in general. Although the DCBF constraints help to reduce the complexity, as discussed in Sec. [III-D.2], it still requires a good initial guess to lead to faster numerical convergence. The initial guess trajectory and control inputs are generated using a braking controller. An acceleration input equal to the maximum deceleration is provided and the steering angle is set to zero. Once the robot comes to a halt, the acceleration input is also set to zero. The braking control inputs, along with the trajectory generated from it are provided as an initial guess to the optimization at each time step. Since at each time step \( b_i(x_{i+1}) \) is solved using (10), the dual optimal solution from this computation is provided as an initial guess for the dual variables for the entire horizon.

6) Simulation Results: To evaluate the performance of (20), we study the navigation problem with two different maze environments with four choices of robot shapes. The optimization problems are implemented in Python with CasADi [38] as modelling language, solved with IPOPT [39] on Ubuntu 18.04 with Intel Xeon E-2176M CPU with a 2.7GHz clock. From the snapshots we can observe tight-fitting obstacle avoidance motion of the robot, and also reversing motion to avoid deadlock. These examples highlight the safety and planning features of our implementation. We also analyze the computational time of trajectory generation using (20), which is shown in TABLE 1. This illustrates that optimization (20) can be solved sufficiently fast to be deployed on different shaped robot for trajectory generation in different maze environments.

| Env | Robot Shape | median | std  | min  | max  |
|-----|-------------|--------|------|------|------|
| Maze 1 | triangle (Fig. 2a) | 51ms | 19ms | 14ms | 149ms |
|       | rectangle (Fig. 2b) | 49ms | 25ms | 15ms | 185ms |

The specific choice of the parameters in the optimization formulation (20) can influence safety and deadlock behaviors in the robot. Qualitatively, for safety, the reference tracking velocity should be such that the robot can come to a halt within the prediction horizon with the input as the maximum deceleration. There is also a trade off between deadlock avoidance and safety: Higher value of the terminal cost weight \( Q_T \) improves deadlock avoidance, but can also increase velocity of the robot leading to unsafe motion.

V. Conclusion

In this paper, we proposed nonlinear optimization formulation using discrete-time control barrier function constraints...
for polytopes. The proposed formulation have been shown to have capabilities to be used as a fast computational online algorithm for control and planning algorithm for general nonlinear dynamical systems. We validated our approach by navigation problems with different robot shapes in maze environments with polytopic obstacles.
