LIKELY PATH TO EXTINCTION IN SIMPLE BRANCHING MODELS WITH LARGE INITIAL POPULATION

KLEBANER F.C. AND LIPTSER R.

Abstract. We give explicit formulae for most likely paths to extinction in simple branching models when initial population is large. In discrete time we study the Galton-Watson process and in continuous time the Branching diffusion. The most likely paths are found with the help of the Large Deviation Principle (LDP). We also find asymptotics for the extinction probability, which gives a new expression in continuous time and recovers the known formula in discrete time. Due to the non-negativity of the processes, the proof of LDP at the point of extinction uses a nonstandard argument of independent interest.

1. Introduction and main results

In population genetics it is often important to look back at the development of populations. In this paper we consider the question of how extinctions occur, and in particular, what path a population takes on the road to extinction. Using asymptotic analysis when initial population values are large, we are able to find most likely path to extinction as well as the extinction probability in two simple branching models in discrete and continuous time. In both examples we use the large deviation principle (LDP) which is non-standard since random processes are nonnegative, and we use trajectories ending up at zero.

One of the contributions of this paper is rigorous proofs of the LDP for processes on half space. It may appear to the reader that the LDP follows from known results in Markov chains and diffusions. This is only partly correct. The standard proof of the lower bound in the local LDP relies on the change of measure. This requires a certain point (the point where maximum in the Fenchel-Legendre transform is achieved) to be finite. In our case this point is at infinity, breaking down the standard approach. We therefore give complete proofs of LDP’s in Sections 4 (discrete time) and 5 (continuous time) following the scheme of Puhalskii [19]. His approach states that the LDP is equivalent to exponential tightness plus local LDP, and is based on the stochastic exponential method (rather than the Laplace transform). Although we follow the scheme of Puhalskii [19] we do not use idempotent probability and give direct proofs. Since these proofs are more technical, we placed them at the end, after results on extinction. Once the LDP is established, the problem of finding most likely path to extinction is in effect the problem of minimization of the rate function. This is typically a difficult problem due to nonlinearity. We are able to solve it by setting up the Bellman equation in discrete case, Section 2 and a dynamical control problem in continuous case, Section 3.

1.1. Galton-Watson process. A prototype of a branching model in discrete time is the Galton-Watson process, described as follows.

Let $X_n$ denote the population size at time $n$, and $\xi_{n+1}^j$ the number of offspring of the $j$th individual. For each $n = 1, 2, \ldots$, $\{(\xi_{n}^j)_{j \geq 1}\}$ is the sequence of independent

identically distributed integer-valued random variables with the probability distribution function \( P(\xi_n^\ell = \ell) = p_\ell, \ \ell = 0, 1, \ldots \). The population size at time \( n + 1 \) is given by

\[
X_{n+1} = \sum_{j=1}^{X_n} \xi_{n+1}^j,
\]

where \( X_0 = K > 0 \). The state \( \{0\} \) is absorbing, and the branching process \( (X_n)_{n \geq 0} \) might be absorbed in \( \{0\} \) at the extinction time

\[
\tau = \inf \{n : X_n = 0\}.
\]

If \( p_0 = 0 \), the population does not become extinct. However if \( p_0 > 0 \), it is well known (e.g. [2], [1]) that the extinction time \( \tau \) is finite with probability one if and only if the offspring mean \( m = \sum_{\ell \geq 1} \ell p_\ell \) does not exceed one (\( m \leq 1 \)). Moreover, for any \( m \), the distribution function of \( \tau \) is computed using the offspring probability generating function \( f(s) = \sum_{\ell \geq 0} p_\ell s^\ell, 0 \leq s \leq 1: \) for any \( N \geq 1, \)

\[
P(\tau \leq N) = (f_N(0))^K,
\]

where \( f_n(s) \) is the \( n \)-th iterate of \( f(s) \), i.e. \( f_n(s) = f(f_{n-1}(s)) \) with \( f_1(0) = f(0) = p_0 \).

A natural question is how to find the “path to extinction” given that extinction occurred at time \( N, \tau = N \). The conditional distribution of the chain conditioned on extinction: for \( n = 1, \ldots, N - 1, \)

\[
\pi_{n|N}(i) := P(X_n = i|\tau = N), \ i = 1, 2, \ldots
\]

gives the complete description. It can be used to find the conditional median or the traditional optimal in the mean square sense estimate \( \hat{X}_n = \sum_{i=1}^N i \pi_{n|N}(i) \).

Unfortunately such computations are involved, even using the Markov property of \( (X_n) \). However for large values of \( X_0 = K \), one path has an overwhelmingly large probability compared to the rest. Consider the normed branching process

\[
x_n^K = \frac{X_n}{K}.
\]

The limit in probability \( \lim_{K \to \infty} x_n^K = \hat{x}_n \) exists (see [10], [11]) and satisfies

\[
\hat{x}_{n+1} = m \hat{x}_n, \ \hat{x}_0 = 1. \quad \text{The process } \hat{x}_n \text{ is always positive, irrespective of the value of } m, \text{ so that, the approximation } \hat{x}_n \text{ is inadequate for study of extinction, the fact is already mentioned in [3].}
\]

In the approach we take, \( (x_n^K)_{n \leq N} \) is approximated on the set \( \{\tau \leq N\} \) by a deterministic sequence \( u^* := (u_n^*)_{n \leq N} \) with \( u_0^* = 1, \) positive \( u_n^* \)'s and \( u_N^* = 0, \) such that for small \( \delta > 0 \) and large \( K, \)

\[
P\left( \sum_{n=1}^{N} \left| x_n^K - u_n^* \right| \leq \delta \right) \approx P(\tau \leq N).
\]

This choice of \( u^* \) might be warranted by the following argument. Since \( f_n(0) \) increases in \( n, \) for large \( K, \) \( (f_N(0))^K \) is considerably larger than any of \( (f_n(0))^K \) for \( n < N. \) Then, by [11],

\[
P(\tau \leq N) = P(\tau = N) + P(\tau \leq N - 1) \approx P(\tau = N).
\]

Consequently, for any \( u = (u_n)_{n \leq N} \) with \( u_0 = 1 \) and \( u_n \geq 0, \)

\[
P\left( \sum_{n=1}^{N} \left| x_n^K - u_n \right| \leq \delta \right) \approx P(\tau \leq N).
\]

For large \( K, \) extinction for the process \( x_n^K \) is a rare event, since the limit process \( \hat{x}_n \) is positive. Therefore, as in [13], we approach the problem of extinction using the large deviations theory, obtaining a new result as well as recover an asymptotic version of the well-known result [14] by using this theory. According to LDP, Theorem [14], and by analogy with the maximal likelihood estimator, the path \( (u_n^*)_{n \leq N} \) is said to be the most likely path to extinction of the normed population \( x_n^K. \)
Clearly, \( \tau \) is the extinction time for both processes \( X_n \) and \( x^K_n \), so that, \( K u^*_n \) (with large \( K \)) sets the pattern for the extinction path in the original branching process.

Figure below demonstrates likely paths to extinction for a binary splitting model with different parameters, \( p = p_0 \), illustrating the general result.

For formulating the main result, we use the log moment generating function, assuming its existence up to some \( t_0 > 0 \),

\[
\log f_n(0) = \log \sum_{\ell \geq 0} e^{t_\ell p_\ell}, \quad t \in (-\infty, t_0).
\] (1.2)

It is related to the moment generating function by

\[
\log f_n(0) \equiv g_n(-\infty) \quad \text{(Lemma 2.1)}.
\]

**Theorem 1.1.** Assume \( p_0 > 0 \) and \( (1.2) \). Then, for any \( N \geq 1 \),

(i)

\[
(u^*_n)_{n \leq N} = \arg \max_{u_0=1, u_N=0} \lim_{u_n>0, n \leq N-1} \lim_{\delta \to 0, K \to \infty} \frac{1}{K} \log P \left( \sum_{n=1}^{N} |x^K_n - u^*_n| \leq \delta \right)
\]

with

\[
u^*_n = \prod_{1 \leq i \leq n} g'(g_{N-i}(-\infty)), \quad n \leq N, \] (1.3)

where \( g_i(t) \) is \( i \)-th iterate of \( g(t) \), \( g_0(t) = t \).

(ii)

\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P \left( \sum_{n=1}^{N} |x^K_n - u^*_n| \leq \delta \right) = \lim_{K \to \infty} \frac{1}{K} \log P(\tau \leq n).
\]

1.2. **Branching diffusion.** In continuous time, we consider the model of a branching diffusion \( X_t \) defined by the Itô equation

\[
dX_t = \alpha X_t dt + \sqrt{X_t} dB_t
\] (1.4)

with a positive initial condition \( X_0 = K \), where \( B_t \) is a Brownian motion, \( \sigma^2 > 0 \), and \( \alpha \in \mathbb{R} \). Stochastic equation \( (1.4) \) possesses a strong nonnegative solution. Since
We analyze the normed process \(x_t\) with the increasing sequence of stopping times \((\tau_i)_{i \geq 1}\):

\[
x_t := X^1_t I_{\{t \leq \tau_1\}} + \sum_{i \geq 1} X^i_{\tau_i} I_{\{\tau_i < t \leq \tau_{i+1}\}},
\]

where \(dX^i_t = \alpha X^i_t dt + \sqrt{|X^i_t| + i^{-1}} dB_t\), \(X^i_0 = K\), and \(\tau_i = \inf\{X^i_t \leq i^{-1}\}\) the increasing sequence of stopping times \((\tau_i)_{i \geq 1}\) relative to the filtration generated by Brownian motion \((B_t)\) (see also Theorem 13.1, [13]). The strong uniqueness of (1.4) follows from Yamada-Watanabe’s theorem (see, e.g. Rogers and Williams, p. 265 [21]) since its drift and diffusion parameters are Lipschitz and Hölder (with coefficient \(\frac{1}{2}\)) continuous respectively. Obviously,

\[
\tau = \inf\{t : X_t = 0\} = \lim_{i \to \infty} \tau_i.
\]

We analyze the normed process \(x^K_t = \frac{X^K_t}{K}\). Due to (1.4), \(x^K_t\) solves the Itô equation

\[
dx^K_t = \alpha x^K_t dt + \frac{\sigma}{\sqrt{K}} \sqrt{x^K_t} dB_t, \quad (1.5)
\]

with \(x^K_0 = 1\). It can be readily shown that \(\lim_{K \to \infty} x^K_t = \hat{x}_t\) exists and solves \(\frac{dx^K_t}{dt} = \alpha \hat{x}_t\), \(\hat{x}_0 = 1\). However, \(\hat{x}_t\) is always positive and is far from to be estimated path to extinction. As in the discrete time, in order to evaluate path to extinction for \((x^K_t)_{t \leq T}\) for fixed \(T > 0\), we approximate \((x^K_t)_{t \leq T}\) on the set \(\{\tau \leq T\}\) by a deterministic function \((u^i_t)_{t \leq T}\) with \(u^0_0 = 1\), \(u^0_T = 0\) and \(u^i_t > 0\), such that for a small \(\delta > 0\) and large \(K\),

\[
P\left(\sup_{t \leq T} |x^K_t - u^i_t| < \delta\right) \geq P\left(\sup_{t \leq T} |x^K_t - u_t| \leq \delta\right)
\]

for any \((u_t)_{t \leq T}\) from the set \(\{u_0 = 1, (u_t > 0)_{t < T}, u_T = 0\}\).

Unfortunately, the useful formula of (1.1) type is not known to us in this case. Here we obtain its asymptotic version as \(K \to \infty\), see (ii) below.

**Theorem 1.2.** For any \(T > 0\),

(i) \(\left(u^i_t\right)_{t \leq T} = \arg\max_{(u_t)_{t \leq T}} \lim_{u_0 = 1, u_T = 0, \delta \to 0, K \to \infty} \lim_{u_t > 0, t < T} \log P\left(\sup_{t \leq T} |x^K_t - u_t| \leq \delta\right)\)

is given by

\[
u^i_t = \begin{cases} e^{-\alpha t} \left(1 - \frac{1-e^{-\alpha t}}{\alpha} \right)^2, & \alpha \neq 0 \\ \left(1 - \frac{t}{T}\right)^2, & \alpha = 0. \end{cases} \quad (1.6)
\]

(ii) \(\lim_{K \to \infty} \frac{1}{K} \log P(\tau \leq T) = \lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left(\sup_{t \leq T} |x^K_t - u^i_t| \leq \delta\right) = -\frac{1}{1-\frac{\alpha}{2\pi T}}\), \(\alpha \neq 0\)

\[
\alpha = 0.
\]

**Corollary 1.** (1) \(u^*\) has the remarkable property: it is the same for subcritical and supercritical case: \(u^*_t(\alpha) \equiv u^*_t(-\alpha)\).
(2) For large $K$, the probability of extinction in $[0, T]$ is given by
\[
P(\tau \leq T) \approx \exp\left(-\frac{K}{\sigma^2} \frac{\alpha}{1-e^{-\alpha T}}\right).
\]

In particular, for $\alpha = 0$, $P(\tau \leq T) \approx e^{-\frac{K}{2\alpha T}}$.

2. Proof of Theorem 1.1

We begin with

**Lemma 2.1.** For any $n \geq 1$, $g_n(-\infty) = \log f_n(0)$.

**Proof.** The result follows by induction from the identity $g_n(\log t) \equiv \log f_n(t)$ for $t \in (0, t_0)$. Write

\[
g(\log(t)) = \log \sum_{\ell \geq 0} e^{\ell \log(t)} p_{\ell} = \log \sum_{\ell \geq 0} e^{\log(t^{\ell})} p_{\ell} = \log \sum_{\ell \geq 0} t^{\ell} p_{\ell} = \log f(t).
\]

If $g_{n-1}(\log t) \equiv \log f_{n-1}(t)$, then

\[
g_n(\log t) = g(g_{n-1}(t) = g(\log(f_{n-1}(t)) = \log(f_{n-1}(t)) = \log(f_n(t)).
\]

□

The proof of Theorem 1.1 is done in a number of steps.

(1) Recall that $g(t)$ is convex function with $g(0) = 0$, $g(-\infty) = \log(p_0)$ and $g'(t) > 0$, $t > -\infty$ while $g'(-\infty) = \lim_{t \to \infty} g'(t) = 0$.

(2) By the local LDP (see, Theorem 1.1), for $u_0 = 1$, $u_N = 0$ and other positive $u_n$’s, it holds

\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left(\sum_{n \leq N} |x_n^K - u_n| \leq \delta\right) = -\sum_{n \leq N} I(u_n, u_{n-1}).
\]

(3) In order to find $(u_n^*)_{n \leq N}$ such that for $u_0 = 1$, $u_n > 0$, $u_N = 0$

\[
\sum_{i \leq n} I(u_i, u_{i-1}) \geq \sum_{i \leq n} I(u_i^*, u_{i-1}^*),
\]

we apply the Dynamic Programming.

Since $u_N = 0$,

\[
I(u_N, u_{N-1}) = \sup_{t \in (-\infty, t_0)} (-u_{N-1}g(t)) = -u_{N-1}g(-\infty) =: B_n(u_{N-1})
\]

(2.2)

is the boundary condition for the Bellman equation

\[
B_n(u_{n-1}) = \inf_{u > 0} \left[ B_{n+1}(u) + I(u, u_{n-1}) \right], \quad 1 \leq n \leq N - 1.
\]

(2.3)

For $n = N - 1$, we have

\[
B_{N-1}(u_{N-2}) = \inf_{u > 0} \left[ -u g(-\infty) + \sup_{t \in (-\infty, t_0)} \{ tu - u_{N-2}g(t) \} \right].
\]

(2.4)

(2.4) provides the inequality,

\[
B_{N-1}(u_{N-2}) \geq \inf_{u > 0} \left[ -u g(-\infty) + tu - u_{N-2}g(t) \right], \quad \forall t \in (-\infty, t_0)
\]

which, with $t = g(-\infty)$, is transformed into

\[
B_{N-1}(u_{N-2}) \geq -u_{N-2}g(-\infty).
\]

(2.5)

We show that the above inequality is equality. For $u, u_{N-2} > 0$, “sup” in (2.4) is attained at the point $t^* = t^*(u, u_{N-2})$, so that, for any $u > 0$,

\[
B_{N-1}(u_{N-2}) \leq u \left[ t^*(u, u_{N-2}) - g(-\infty) \right] - u_{N-2}g(t^*(u, u_{N-2})).
\]
We choose \( u = u^*_{N-1} \) such that \( t^*(u^*_{N-1}, u_{N-2}) = g(-\infty) \). This is possible since
\[
\begin{align*}
g(-\infty) &= \log p_0, \quad t^*(0, u_{N-2}) = -\infty, \\
g'(-\infty) &= 0, \quad t^*(m, u_{n-2}) = 0, \quad g'(0) = m,
\end{align*}
\]
so that, the existence of \( u^*_{N-1} \) follows from continuity, in \( u \), of \( t^*(u, u_{N-2}) \).

The choice of \( u^*_{N-1} \) gives the inequality
\[
B_{N-1}(u_{N-2}) \leq -u_{N-2}g(t^*(u^*_{N-1}, u_{N-2})) = g(g(-\infty)) = g_2(-\infty).
\]

Consequently, the opposite inequality for (2.5) holds true and, therefore,
\[
B_{N-1}(u_{N-2}) = -u_{N-2}g_2(-\infty).
\]

It is obvious too that for any \( u_{N-2} > 0 \),
\[
u^*_{N-1} = u_{N-2}g'(t^*(u^*_{N-1}, u_{N-2})) = u_{N-2}g'(g(-\infty)).
\]

Further, by induction, we find the following pairs:
\[
\begin{align*}
u^*_{N-1} &= g'(g(-\infty))u^*_{N-2} \\
B_{N-1}(u^*_{N-2}) &= -g_2(-\infty)u^*_{N-2} \\
\ldots \\
u^*_{N-2} &= g'(g_2(-\infty))u^*_{N-3} \\
B_{N-2}(u^*_{N-3}) &= -g_3(-\infty)u^*_{N-3} \\
\vdotswithin{\ldots}
\vdotswithin{\ldots}
\vdotswithin{\ldots}
\vdotswithin{\ldots}
u^*_{1} &= g'(g_{n-1}(-\infty))u_0 \\
B_{1}(u_0) &= -g_n(-\infty)u_0 (u_0 = 1).
\end{align*}
\]

With chosen \((u^*_n)_{1\leq n \leq N-1}\), the Bellman equation (2.5) is transformed into the backward recurrent equation
\[
B_n(u_{n-1}) = B_{n+1}(u^*_n) + I(u^*_n, u^*_{n-1}), \quad 1 \leq n \leq N - 1
\]
with boundary condition \(-u^*_{N-1}g(-\infty)\) (see, (2.2)).

Thus, \( B_1(1) = \sum_{1 \leq n \leq N} I(u^*_n, u^*_{n-1}) \).

On the other hand, the Bellman equation also yields
\[
B_1(1) \geq \sum_{1 \leq n \leq N-1} I(u_n, u_{n-1}) + B_N(u_{N-1}) = \sum_{1 \leq n \leq N} I(u_n, u_{n-1})
\]
what proves (2.4).

(4) We recall that \( \sum_{n \leq N} I(u^*_n, u^*_{n-1}) = -g_n(-\infty) \), that is, by Lemma 2.1 and (1.3),
\[
\sum_{1 \leq n \leq N} I(u^*_n, u^*_{n-1}) = -\log f_N(0) = \frac{1}{K} \log P(\tau \leq N), \quad \forall \ K > 0.
\]

(5) Thus, (1)-(3) imply the statement (i); formula (1.3) follows from recurrence
\[
u^*_n = g'(g_2(-\infty))u^*_n - 1, \quad u^*_0 = 1.
\]

Finally (ii) follows from (4). \( \square \)
3. **Proof of Theorem 1.2**

We apply the LDP Theorem 5.1. By the local LDP, with \( u_0 = 1, \ u_t > 0 \) and \( u_T = 0 \), we have

\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P \left( \sup_{t \leq T} \left| J^K - u_t \right| \leq \delta \right) = -J_T(u),
\]

where \( J_T(u) = \left\{ \begin{array}{ll} \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_t - u_t)^2}{u_t} I_{(u_t > 0)} \, dt, & u_0 = 1, \, du_t = \dot{u}_t \, dt \\ \infty, & \text{otherwise.} \end{array} \right. \)

Therefore (i) is reduced to minimization of \( J_T(u) \) in a class of absolutely continuous test functions \( u_t \) with \( u_0 = 1, \ u_t > 0 \) and \( u_T = 0 \).

Set \( w_t = \frac{\dot{u}_t - u_t}{\sqrt{u_t}}, \ t \in [0, T) \) and notice that the minimization of \( J_T(u) \) is equivalent to the following control problem with the controlled process \( u_t \), solving a differential equation

\[
\dot{u}_t = \alpha u_t + \sqrt{u_t} w_t, \quad t \in [0, T)
\]

subject to \( u_0 = 1 \). The control action \( w_t \) belongs to a class of measurable functions with \( \int_0^T w_t^2 \, dt < \infty \) bringing \( u_t \) to zero at the time \( T \). The control action \( w_t^* \) from this class is optimal if for any \( w_t \),

\[
\int_0^T (w_t^*)^2 \, dt \leq \int_0^T w_t^2 \, dt.
\]

If \( w_t^* \) exists, then the controlled process \( u_t^* \) related to \( w_t^* \) minimizes \( J_T(u) \) in the required class of continuous functions \( u = (u_t)_{t \leq T} \).

In order to find \( w_t^* \), it is convenient to deal with (recall \( u_t > 0 \)) \( v_t = \sqrt{u_t} \) since \( v_t \) solves the linear differential equation \( \dot{v}_t = \frac{\alpha}{2} v_t + \frac{1}{2} w_t, \ v_0 = 1 \). If \( w_t^* \) exists, then \( w_t^* \) brings \( v_t \) to zero at the time \( T \), that is, \( 0 = v_T = e^{\frac{\alpha}{2} T} + \int_0^T e^{\frac{\alpha}{2} (T-t)} w_t^* \, dt \) or, equivalently,

\[
-1 = \frac{1}{2} \int_0^T e^{-\frac{\alpha}{2} t} w_t^* \, dt. \tag{3.1}
\]

Hence, by the Cauchy-Schwarz inequality \( 1 \leq \frac{1}{2} \int_0^T e^{-\alpha t} \, dt \int_0^T (w_t^*)^2 \, dt \), that is, the following lower bound holds: \( \int_0^T (w_t^*)^2 \, dt \geq \frac{2\alpha}{1 - e^{-\alpha T}} \). This lower bound is valid for any \( w_t \) providing (3.1), so that, the condition

\[
\int_0^T (w_t^*)^2 \, dt = \frac{2\alpha}{1 - e^{-\alpha T}}
\]

is valid for \( w_t^* = c e^{-\frac{\alpha}{2} t} \), for any constant \( c \), bring \( w_t^* = c^* e^{-\frac{\alpha}{2} t} \) with \( c^* \) solving

\[
-1 = \int_0^T e^{-\frac{\alpha}{2} t} w_t^* \, dt = c^* \int_0^T e^{-\alpha t} \, dt.
\]

Hence,

\[
c^* = \left\{ \begin{array}{ll} \frac{-2\alpha}{1 - e^{-\alpha T}}, & \alpha \neq 0 \\ -\frac{2}{T}, & \alpha = 0 \end{array} \right. \quad \text{and} \quad w_t^* = \left\{ \begin{array}{ll} \frac{2\alpha e^{-\frac{\alpha}{2} t}}{1 - e^{-\alpha T}}, & \alpha \neq 0 \\ \frac{2}{T}, & \alpha = 0 \end{array} \right.
\]

\[
\int_0^T (w_t^*)^2 \, dt = \left\{ \begin{array}{ll} \frac{2\alpha}{1 - e^{-\alpha T}}, & \alpha \neq 0 \\ \frac{2}{T}, & \alpha = 0 \end{array} \right.
\]
Finally, we find that
\begin{align*}
u_t^* &= e^{\tau_\omega^*} - \frac{\alpha}{1 - e^{-T\alpha}} \int_0^t e^{(t-s)\tau_\omega^*} e^{-s\tau_\omega^*} ds \\
&= e^{\tau_\omega^*} \left[ 1 - \frac{1 - e^{-t\alpha}}{1 - e^{-T\alpha}} \right] = e^{\tau_\omega^*} \left( e^{-t\alpha} - e^{-T\alpha} \right)
\end{align*}
and, since \( u_t^* = (v_t^*)^2 \), we obtain \( (3.2) \) and the proof of (i) is complete.

(ii) By (i),
\[ J_T(u^*) = \frac{1}{\sigma^2} \alpha \]

We show that
\[ \lim_{K \to \infty} \frac{1}{K} \log P(\tau \leq T) = J_T(u^*). \]

To this end, use the fact that \( \{ \tau \leq T \} = \{ (\omega, t) : \exists t \leq T, x_t^K(\omega) = 0 \} \). For notational convenience denote \( \mathfrak{A} := \{ \tau \leq T \} \). Set \( \mathfrak{A}^d \) and \( \mathfrak{A}^{\text{int}} \) the closure and interior of \( \mathfrak{A} \). Then, by the LDP, we have
\begin{align*}
\lim_{K \to \infty} \frac{1}{K} \log P(\mathfrak{A}^d) &\leq - \inf_{u : \{ u_{n>0, s<t} = 0 \}} J_t(u) = - \inf_{t \leq T} \min \{ u_{t=0} \} J_t(u^*) \\
\lim_{K \to \infty} \frac{1}{K} \log P(\mathfrak{A}^{\text{int}}) &\geq - \inf_{u : \{ u_{n>0, s<t} = 0 \}} J_t(u) = - \inf_{t \leq T} \min \{ u_{t=0} \} J_t(u^*)
\end{align*}
Since \( \lim_{K \to \infty} = \lim_{K \to \infty} = \lim_{K \to \infty} \) implies the existence of \( \lim_{K \to \infty} \), it remains to show that \( \inf_{t \leq T} J_t(u^*) = J_T(u^*) \).

Notice that \( (3.2) \) is valid with \( T \) replaced by any \( t < T \) with \( u^* \) replaced by the corresponding \( u^{*,t} = \{ u_0^{*,t} = 1; u_{s<t}^{*,t} > 0; u_{t}^{*,t} = 0 \} \). In other words, for any \( t \),
\[ J_t(u^{*,t}) = \frac{1}{\sigma^2} \alpha \]
and \( J_t(u^{*,t}) \) increases to \( J_T(u^*) \) with \( t \searrow T \). \( \square \)

4. LDP in Discrete Time

Let \( m = \inf \{ n \leq N : u_n = 0 \} \) and \( m = \infty \) if all \( (u_n)_{n \leq N} \) are positive.
\[ I(y, x) = \sup_{t \in (-\infty, m]} \left[ ty - xg(t) \right]. \]

**Theorem 4.1.** Assume \( \mathfrak{A}^d \). For any \( N \geq 1 \), the family \( \{ (x_n^K)_{n \leq N} \}_{K \to \infty} \) obeys the LDP in \( \mathbb{R}^N_+ \), supplied by the Euclidian metric \( g_N \), with the speed \( \frac{1}{\sqrt{N}} \) and the rate function
\[ J_N(u) = \begin{cases} 
\sum_{n=1}^{m-1} I(u_n, u_{n-1}) - u_{m-1} \log(p_m), & u_0 = 1, u_{n>0, n>m} \\
\sum_{n=1}^{N} I(u_n, u_{n-1}), & u_0 = 1, u_{n>0, n \leq N}, \\
\infty, & \exists \ n : u_n = 0, u_{n+1} > 0 \text{ or } u_0 \neq 1
\end{cases} \]

**Remark 1.** LDP for branching processes have been considered in the literature, see, for example, \( 2, 7, 8 \). However, they were concerned with the sequence \( \frac{X_n}{n} \), as \( n \to \infty \), whereas here we consider the LDP for \( X_n \) processes indexed by the large initial value.
Remark 2. The nonnegativity of $x_n^K$ provides some difficulty for verification of LDP at the “point of extinction” where the test function becomes zero. For set $S$ of test functions that keep away from zero the statement of the theorem is implied by a result in Klebaner and Zeitouni, [9] and other known results that can be adapted to our setting (see, e.g. Kifer, [8], Puhalskii, [19], Klebaner and Liptser, [12], etc.). But $\{\tau \leq N\} \not\in S$, and for the sake of completeness and accuracy we give the complete proof below, with a new proof of the lower bound in the local LDP.

4.1. Proof of Theorem 4.1. We follow standard (necessary and sufficient) conditions for proving the LDP by showing the exponential tightness:

$$
\lim_{C \to \infty} \lim_{K \to \infty} \frac{1}{K} \log P\left( \Omega \setminus K_C \right) = -\infty
$$

with compacts $K_C = \{\max_{1 \leq n \leq N} x_n \leq C\}, C \nearrow \infty$, and the local LDP:

$$
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left( g_N(x^K, u) \leq \delta \right) = -J_N(u).
$$

Notice that (A) implies the existence of a stochastic exponential, with $t_n \leq Kt_0$,

$$
\mathbb{E}^{t_n} = \prod_{n=1}^{N} \mathbb{E}\left( e^{t_n x_n^K} \mid \mathcal{F}_{n-1} \right),
$$

where $(\mathcal{F}_n)_{n \geq 0}$ is the filtration, with $\mathcal{F}_0 = \{\emptyset, \Omega\}$, generated by $(x_n^K)_{n \geq 1}$.

Set

$$
\mathbb{E}^{t_n} = e^{\sum_{t_n \leq t_n} \log \mathbb{E}^{t_n}(x_1^K, \ldots, x_{n-1}^K)},
$$

(4.1)

The random process $(\mathbb{E}^{t_n}, \mathcal{F}_n)_{n \leq N}$ is the (positive) martingale,

$$
\mathbb{E}^{t_n} = 1.
$$

4.1.1. Exponential tightness. Since $\max_{1 \leq n \leq N} x_n^K \leq \sum_{1 \leq n \leq N} x_n^K$, it is enough to show

$$
\lim_{C \to \infty} \lim_{K \to \infty} \frac{1}{K} \log P\left( \sum_{1 \leq i \leq N} x_i^K \geq C \right) = -\infty.
$$

Set $t^* = \arg\max_{t \in (-\infty, t_0]} \left( t - g(t) \right)$. Since $g(0) = 0$, we have that $t^* \in (0, t_0)$ and $g(t^*) < t^*$. We choose $t_n \equiv t^* K(< Kt_0)$, and introduce $\mathbb{A} = \{\sum_{1 \leq i \leq n} x_i^K \geq C\}$.

With chosen $t_n$, we have $\mathbb{E}\mathbb{A} = 1$ and, therefore, $\mathbb{E}\mathbb{A} \leq 1$. Taking into account this inequality and (4.1), write

$$
1 \geq \mathbb{E}\mathbb{A} e^{\sum_{1 \leq i \leq n} t^* x_n^K - \log \mathbb{E}^{t_n}(x_1^K, \ldots, x_{n-1}^K)}
$$

$$
= \mathbb{E}\mathbb{A} e^{K t^* \sum_{1 \leq i \leq n} x_n^K - K \log (t^*) \sum_{1 \leq i \leq N} x_n^K - K \log (t^*)}
$$

$$
\geq \mathbb{E}\mathbb{A} e^{K t^* \sum_{1 \leq i \leq n} x_n^K - K \log (t^*) - K \log (t^*)}
$$

$$
\geq \mathbb{E}\mathbb{A} e^{K t^* - g(t^*) - K \log (t^*)} = e^{Kt^*} |t^* - g(t^*) - K \log (t^*)| P(\mathbb{A}).
$$

Therefore,

$$
\frac{1}{K} \log P(\mathbb{A}) \leq - \frac{1}{K} \log (t^* - g(t^*)) |C + g(t^*)| \to -\infty.
$$

\[ \square \]

4.1.2. Local LDP. Upper bound. We may restrict ourselves by the test function $u = \{u_1, \ldots, u_{N-1}, u_N\}$ and show that

$$
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left( g_N(x^K, u) \leq \delta \right) \leq -J_N(u).
$$

(4.3)
Hence, taking into account that \( \lim_{t \to t_0} \) is similar.

For test function with \( u_n = 0 \), \( u_{n+1} > 0 \) or \( u_0 \neq 1 \), \( \{4.3\} \) is obvious. For others test functions the verification of \( \{4.3\} \) is reduced to the above-mentioned ones.

Let now \( \mathfrak{A} = \{ \rho_N(x^K, u) \leq \delta \} \). By \( \{4.2\} \), we have

\[
1 \geq \mathbb{E} \mathcal{M} e^{\sum_{1 \leq k \leq n|} [u_n x^K - K_{n-1} x^K + g(t_n^*)]}.
\]

(4.4)

Set \( t_n^* = \arg\max_{t_n \in (-\infty, t_0]} [u_n x_n - u_{n-1} g(t_n)] \), \( n \leq N - 1 \), and \( t_N = -l \) \((l > 0)\), and take \( t_n = K t_n^* \), then we derive from \( \{4.3\} \)

\[
1 \geq \mathbb{E} \mathcal{M} e^{K \sum_{1 \leq n \leq N} [u_n x_n - u_{n-1} g(t_n^*)] - K \sum_{1 \leq n \leq N}(t_n^* + \delta)}
\]

\[
= \mathbb{E} \mathcal{M} e^{K \sum_{1 \leq n \leq N-1} [u_n x_n - u_{n-1} g(-l)] - K \sum_{1 \leq n \leq N}(t_n^* + \delta)}
\]

\[
= \mathbb{E} \mathcal{M} e^{K [J_{N-1}(u) - u_{N-1} g(-l)] - K \sum_{1 \leq n \leq N}(t_n^* + \delta)}.
\]

Hence, taking into account that \( \lim_{t \to \infty} g(-l) = \log(p_0) \), we obtain

\[
\frac{1}{K} \log P(\mathfrak{A}) \leq -[J_{N-1}(u) + u_{N-1} g(-l)] + \sum_{1 \leq i \leq N-1} (|t_i^*| + |g(t_i^*)|) \delta
\]

\[
\xrightarrow[t \to 0]{\delta} -[J_{N-1}(u) + u_{N-1} g(-l)] \xrightarrow[t \to \infty]{} -J_N(u).
\]

4.2. Local LDP. Lower bound. Obviously for \( u \) with \( J_N(u) = \infty \), it is nothing to verify. Further as in the upper bound verification, we may restrict ourselves by the test function \( u = \{u_1, \ldots, u_{N-1}, u_N\} \) with \( \xi_1 = 0 \) and show that

\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left( \rho_N(x^K, u) \leq \delta \right) \geq -J_N(u).
\]

Write

\[
\{ \rho_N(x^K, u) \leq \delta \} = \{ \rho_{N-1}(x^K, u) + x_N^K \leq \delta \}
\]

\[
\sup \{ \rho_{N-1}(x^K, u) \leq 0.5 \delta, \ x_N^K \leq 0.5 \delta \}
\]

\[
\sup \{ \rho_{N-1}(x^K, u) \leq 0.5 \delta, \ x_N^K = 0 \}
\]

\[
\sup \left\{ \rho_{N-1}(x^K, u) \leq 0.5 \delta, \ \frac{1}{K} \sum_{j=1}^{K_{(u_{N-1} - \delta)}} \xi_j^1 = 0 \right\}
\]

\[
\sup \left\{ \rho_{N-1}(x^K, u) \leq 0.5 \delta, \ \frac{1}{K} \sum_{j=1}^{K_{(u_{N-1} + \delta)}} \xi_j^1 = 0 \right\}
\]

\[
= \left\{ \rho_{N-1}(x^K, u) \leq 0.5 \delta, \ \sum_{j=1}^{K_{(u_{N-1} + \delta)}} \xi_j^1 = 0 \right\}
\]

The sets \( \mathfrak{A}_1 = \{ \rho_{N-1}(x^K, u) \leq 0.5 \delta \} \) and \( \mathfrak{A}_2 = \{ \sum_{j=1}^{K_{(u_{N-1} + \delta)}} \xi_j^1 = 0 \} \) are independent, so that,

\[
P(\rho_N(x^K, u) \leq \delta) \geq P(\rho_{N-1}(x^K, u) \leq 0.5 \delta) P^{K_{(u_{N-1} + \delta)}}(\xi_1^1 = 0).
\]

Consequently,

\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\rho_N(x^K, u) \leq \delta)
\]

\[
\geq \lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\rho_{N-1}(x^K, u) \leq 0.5 \delta) + u_{N-1} \log P(\xi_1^1 = 0).
\]
We verify (4.7) by showing
\[ 
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left( \varrho_{N-1}(x^K, u) \leq \delta \right) \geq -J_{N-1}(u),
\] provided that \( u_n > 0, n \leq N - 1 \), the required lower bound holds true.
Thus, it is left to verify the validity of (4.5).
Set \( \Lambda_{N-1}(x^K) = \sum_{n=1}^{N-1} K \left[ t_n^* x^K - t_n^* - \varrho(t_n^*) \right] \), \( \varepsilon \Lambda_{N-1}(x^K) = 1 \).

We introduce the probability measure \( Q^K_{N-1} \) with \( dQ^K_{N-1} = \Lambda_{N-1}(x^K) dP \). Since \( \Lambda_{n-1}(x^K) > 0 \), \( P \)-a.s., we also have \( dP = \Lambda_{n-1}(x^K) dQ^K_{n-1} \).

In particular, for \( \mathfrak{A} = \left\{ \varrho_{N-1}(x^K, u) \leq \delta \right\} \),
\[ 
P(\mathfrak{A}) = \int_{\mathfrak{A}} \Lambda_{N-1}(x^K) dQ^K_{N-1}.
\]

So, the following lower bound, on the set \( \mathfrak{A} \), is valid:
\[ 
\Lambda_{N-1}(x^K) \geq e^{-K J_{N-1}(u) - K \delta \max_{n \leq N-1} \left( |t_n^*| + |\varrho(t_n^*)| \right)}
\]
\[ 
\geq e^{-K J_{N-1}(u) - K \delta \max_{n \leq N-1} \left( |t_n^*| + |\varrho(t_n^*)| \right)}
\]
or, equivalently,
\[ 
\frac{1}{K} \log P(\mathfrak{A}) \geq -J_{N-1}(u) - \delta \max_{n \leq N-1} \left( |t_n^*| + |\varrho(t_n^*)| \right) + \frac{1}{K} \log Q^K_{N-1}(\mathfrak{A}).
\]

The latter inequality implies (4.5) if
\[ 
\lim_{K \to \infty} \frac{1}{K} \log Q^K_{N-1}(\mathfrak{A}) = 0.
\] (4.6)

A simple condition, providing (4.7), is \( \lim_{K \to \infty} Q^K_{N-1}(\mathfrak{A}) = 1 \) or, equivalently,
\[ 
\lim_{K \to \infty} Q^K_{N-1}(\varrho_{N-1}(x^K, u) > \delta) = 0.
\] (4.7)

We verify (4.7) by showing\(^1\)
\[ 
E_{N-1}^K \varrho_{N-1}^2(x^K, u) = \frac{u_{N-1}}{K} \sum_{n=1}^{N-1} \frac{u_{n-1}}{u_n^2} \varrho''(t_n^*).
\] (4.8)

Notice that the positiveness of \( (u_n)_{n \leq N-1} \) provides a boundedness for the right hand side of (4.8) and, in turn by Chebyshev’s inequality, the validity of (4.7).

In order to establish (4.9), we apply the identity relative to \( t_n^* \):
\[ 
1 = E \left( \frac{\Lambda_n(x^K)}{\Lambda_{n-1}(x^K)} \bigg| \mathscr{F}_{n-1} \right) = E e^{K \left[ t_n^* x^K - t_n^* - \varrho(t_n^*) \right]} \bigg| \mathscr{F}_{n-1} \right).
\] (4.9)

Differentiating twice (4.9) in \( t_n^* \), we find that
\[ 
0 = E \left( \frac{-K x^K - \varrho'(t_n^*)}{\Lambda_{n-1}(x^K)} \bigg| \mathscr{F}_{n-1} \right) \frac{\Lambda_n(x^K)}{\Lambda_{n-1}(x^K)} \bigg| \mathscr{F}_{n-1} \right),
\] (4.10)

By the Bayes formula, e.g. (177, 13): for any integrable random variable \( \alpha \),
\[ 
E_{N-1}^K (\alpha | \mathscr{F}_{n-1}) = E \left( \frac{\alpha \Lambda_n(x^K)}{\Lambda_{n-1}(x^K)} \bigg| \mathscr{F}_{n-1} \right).
\]

\(^1\) \( E_{N-1}^K \) denotes the expectation with respect to \( Q^K_{N-1} \).
By taking $\alpha = x_n^K$ and $\alpha = [x_n^K - x_{n-1}^K \theta'(t^*_n)]^2$, we derive with the help of (4.11) that
\[
E^K_{N-1}(x_n^K | \mathcal{F}_{n-1}) = x_{n-1}^K \theta'(t^*_n)
\]  
(4.11)

\[
E^K_{N-1}((x_n^K - x_{n-1}^K \theta'(t^*_n))^2 | \mathcal{F}_{n-1}) = \frac{x_{n-1}^K \theta''(t^*_n)}{K}
\]  
(4.12)

Since $u_n, u_{n-1}$ are positive, we have $\theta'(t^*_n) = \frac{u_n}{u_{n-1}}$. Hence and by (4.11), we obtain that
\[
E^K_{N-1}x_n^K = \frac{u_n}{u_{n-1}}E^K_{N-1}x_{n-1}^K.
\]
Consequently, iterating the above recursion and taking into account $u_0 = 1$, we find that
\[
E^K_{N-1}x_n^K = u_n.
\]

Further, with the help of (4.12) we find a recursion
\[
E^K_{N-1}(x_n^K)^2 = \left(\frac{u_n}{u_{n-1}}\right)^2 E^K_{N-1}(x_{n-1}^K)^2 + u_{n-1} \theta''(t^*_n)/K.
\]

By using $E^K_{N-1}(x_n^K - u_n)^2 = E^K_{N-1}(x_{n-1}^K)^2 - u_n^2$ and $u_n^2 = \left(\frac{u_n}{u_{n-1}}\right)^2 u_{n-1}^2$, we establish a recursion for $\Delta_n = E^K_{N-1}(x_n^K - u_n)^2$:
\[
\Delta_n = \left(\frac{u_n}{u_{n-1}}\right)^2 \Delta_{n-1} + u_{n-1} \theta''(t^*_n)/K
\]
supplied by $\Delta_0 = 0$. Then, by $\frac{\Delta_n}{u_n^2} = 0$ and
\[
\frac{\Delta_n}{u_n^2} = \frac{\Delta_{n-1}}{u_{n-1}^2} + \frac{u_{n-1}}{u_n^2} \frac{\theta''(t^*_n)}{K}, \quad \frac{\Delta_{n-1}}{K} = \sum_{n=1}^{N-1} \frac{u_{n-1}}{u_n^2} \theta''(t^*_n).
\]

It is left to recall that $\Delta_{n-1} = E^K_{N-1} \theta''(x_n^K, u_n)$.

5. LDP in Continuous Time

We introduce the filtration $(\mathcal{F}_t^B)_{t \geq 0}$ generated by Brownian motion $B_t$, with the general conditions. All random processes considered in this section are adapted to this filtration. Henceforth, by agreement,
\[
0 = 0.
\]

**Theorem 5.1.** For any $T > 0$, the family $\{(x^K_t)_{t \leq T}\}_{K \to \infty}$ obeys the LDP in $C_{[0,T]}(\mathbb{R}_+)$, supplied by the uniform metric $\delta_T$, with the speed $\frac{1}{K}$ and the rate function
\[
J_T(u) = \left\{ \begin{array}{ll}
\frac{1}{2\sigma^2} \int_0^T \frac{(u_t - \alpha u_t)^2}{u_t} dt, & u_0 = 1, du_t = \dot{u}_t dt, \\
\infty, & otherwise.
\end{array} \right.
\]

**Remark 3.** Since $u_t \geq 0$, Freidlin-Wentzell’s rate function, $[3]$, $\frac{1}{2\sigma^2} \int_0^T \frac{(u_t - \alpha u_t)^2}{u_t} dt$ is not compatible with $u_t = 0$. Our branching diffusion model is a very particular case of a model studied by Puhalskii in [20]. To apply the LDP analysis from [20] to the family $\{(x^K_t)_{t \leq T}\}_{K \to \infty}$, one has to “disentangle” many details of the proof to make it compatible with our case. Finally, in Donati-Martin et all, [9], the LDP analysis deals with a rate function of the following type $\int_0^T \frac{(u_t - \alpha u_t)^2}{u_t} dt$ for $u_t \geq 0$ related to a family of diffusion type processes without extinction. A reader interested in details of the direct proof can find them below.
Proof. It suffices to verify:

(i) $C$-exponential tightness (see [15]),

\[
\lim_{C \to \infty} \lim_{K \to \infty} \frac{1}{K} \log P \left( \sup_{t \leq T} x^K_t \geq C \right) = -\infty, \tag{5.1}
\]

\[
\lim_{\Delta \to 0} \lim_{K \to \infty} \sup_{\gamma \leq T} \frac{1}{K} \log P \left( \sup_{t \leq \Delta} \left| x^K_{t+\gamma} - x^K_\gamma \right| \geq \eta \right) = -\infty, \forall \eta > 0, \tag{5.2}
\]

where $\gamma$ is stopping time relative to $(\mathcal{F}^B_t)_{t \geq 0}$.

(ii) the Local LDP,

\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P \left( \sup_{t \leq T} \left| x^K_t - u_t \right| \leq \delta \right) = -J_T(u). \tag{5.3}
\]

(i)-Verification. The Itô equation (1.5) is equivalent to the integral equation

\[
x^K_t = e^{\alpha t} \left( 1 + \frac{1}{\sqrt{K}} \int_0^t e^{-\alpha s} \sqrt{x^K_s} dB_s \right).
\]

Hence,

\[
\sup_{t \leq T} x^K_t \leq 2e^{\alpha |T|} \left( 1 \vee \sup_{\sqrt{K} \leq T} \int_0^t e^{-\alpha s} \sqrt{x^K_s} dB_s \right), \tag{5.4}
\]

so that, (5.3) holds true provided that

\[
\lim_{C \to \infty} \lim_{K \to \infty} \frac{1}{K} \log P \left( \sup_{t \leq T} e^{-\alpha s} \sqrt{x^K_s} dB_s \geq \sqrt{KC} \right) = -\infty. \tag{5.5}
\]

In order to verify (5.5), let us introduce a continuous martingale and its variation process

\[
M_t = \frac{\sigma}{\sqrt{K}} \int_0^t e^{-\alpha s} \sqrt{x^K_s} dB_s \quad \text{and} \quad \langle M \rangle_t = \frac{\sigma^2}{K} \int_0^t e^{-2\alpha s} x^K_s ds
\]

respectively and the stopping time $\tau_C = \inf \{ t \leq T : M_t \geq C \}$, where $\inf \{ \emptyset \} = \infty$ which enables us to claim that (5.5) is valid if

\[
\lim_{C \to \infty} \lim_{K \to \infty} \frac{1}{K} \log P \left( \tau_C \leq T \right) = -\infty. \tag{5.6}
\]

We proceed with verification of (5.6). With $\lambda > 0$, set

\[
\delta_t = e^{\lambda M_t - \frac{1}{2} \langle M \rangle_t}. \tag{5.7}
\]

It is well known that the process $(\delta_t, \mathcal{F}^B_t)_{t \geq 0}$ is the positive local martingale and so, the supermartingale too with $\mathcal{E}_{\theta} \leq 1$ for any stopping time $\theta$ relative to $(\mathcal{F}^B_t)$. By choosing $\theta = \tau_C$, we find that $1 \geq \mathcal{E}_t(\theta \leq T \mid \mathcal{F}_t \cap \{ T > t \}) \mathcal{E}_t(\theta \leq T)$ and (5.6) there exists positive $l$ such that

\[
\log \delta_t \geq \lambda C - \frac{\sigma^2 \lambda^2}{2K} \int_0^\theta e^{-2\alpha s} x^K_s ds \geq \lambda C - \frac{1}{2K} (1 + C).
\]

Further, a choice of $\lambda = \frac{KC}{(1+C)}$ implies $\delta_t \geq e^{\frac{K\delta^2}{1+C}}$. Consequently,

\[
\frac{1}{K} \log P \left( \tau_C \leq T \right) \leq - \frac{C^2}{(1+C)l} \lim_{C \to \infty} -\infty.
\]

By (5.1), the proof of (5.2) is reduced to the verification of two conditions: for any $\eta, C > 0$,

\[
\lim_{\Delta \to 0} \lim_{K \to \infty} \sup_{\gamma \leq T} \frac{1}{K} \log P \left( \sup_{t \leq \Delta} \int_\gamma^{\gamma+t} x^K_s ds \geq \eta, \sup_{s \leq T} x^K_s \leq C \right) = -\infty.
\]

\[
\lim_{\Delta \to 0} \lim_{K \to \infty} \sup_{\gamma \leq T} \frac{1}{K} \log P \left( \sup_{t \leq \Delta} \int_\gamma^{\gamma+t} \sqrt{x^K_s} dB_s \geq \eta, \sup_{s \leq T} x^K_s \leq C \right) = -\infty.
\]
The first is obvious while the second is equivalent to

\[
\lim_{\Delta \to 0} \lim_{K \to \infty} \sup_{\gamma \leq T} \frac{1}{K} \log P \left( \sup_{t \leq \Delta} I_{t,C} | M_{\gamma \gamma+t}^K - M_{\gamma+t}^K | \geq \eta \right) = -\infty,
\]

where \( I_{t,C} = I_{\{\sup_{s \leq t} x^K_s \leq C\}}, \ t \leq T. \)

Set \( N^K_t = M^K_{\gamma+t} - M^K_\gamma \) and notice that \( (N^K_t, \mathcal{F}_\gamma^B)_{t \geq 0} \) is a local martingale with the variation process \( \langle N^K \rangle_t = \frac{\sigma^2}{K} \int_\gamma^{\gamma+t} x^K_s \, ds. \)

Further, the use of \( I_{t,C} N^K_t = I_{t,C} \int_0^t I_{s,C} dN^K_s \) simplifies \( 5.7 \) to

\[
\lim_{\Delta \to 0} \lim_{K \to \infty} \sup_{\gamma \leq T} \frac{1}{K} \log P \left( \sup_{t \leq \Delta} \left| \int_0^t I_{s,C} dN^K_s \right| \geq \eta \right) = -\infty.
\]

The local martingale \( N^K_{t,C} := \int_0^t I_{s,C} dN^K_s \) possesses the variation process

\[
\langle N^K_{t,C} \rangle_t = \int_0^t I_{s,C} \, \langle N^K \rangle_s = \frac{\sigma^2}{K} \int_0^t I_{s,C} x^K_s \, ds,
\]

that is, \( d\langle N^K_{t,C} \rangle_t \leq \frac{\sigma^2 C}{K} dt. \)

Now, we are able to verify \( 5.7 \) with the help of stochastic exponential technique. Let

\[
\tilde{\eta}(\lambda) = e^{\lambda N^K_{t,C}} - \frac{\lambda^2}{2} \langle N^K_{t,C} \rangle_t, \quad \lambda \in \mathbb{R}.
\]

Since \( \tilde{\eta}(\lambda) \) is a continuous local martingale and supermartingale too, for any stopping time \( \theta, \mathbb{E} \tilde{\eta}(\lambda) \leq 1. \) Let \( \theta = \inf \{ t \leq \Delta : N^K_{t,C} \geq \eta \} \). Taking into account that \( \{ \theta \leq \Delta \} = \{ N^K_{\theta+C} \geq \eta \} \), write

\[
1 \geq \mathbb{E} I_{\{ \theta \leq \Delta \}} \tilde{\eta}(\lambda).
\]

The value \( \tilde{\eta}(\lambda) \) is evaluated below on the set \( \{ \theta \leq \Delta \} \) as follows: with \( \lambda > 0 \) and \( \langle N^K_{t,C} \rangle_\theta \leq \frac{\sigma^2 C}{K} \theta \leq \frac{\sigma^2 C}{K} \Delta, \)

\[
\tilde{\eta}(\lambda) \geq e^{\lambda \eta - \frac{\lambda^2 \sigma^2 C}{2K} \Delta}.
\]

Therefore,

\[
\log \mathbb{P}(\theta \leq \Delta) \leq - \left[ \lambda \eta - \frac{\lambda^2 \sigma^2 C}{2K} \Delta \right] \text{ and the choice of } \lambda = \frac{K \eta}{\sigma^2 C \Delta} \text{ provides}
\]

\[
\frac{1}{K} \log \mathbb{P}(\theta \leq \Delta) \leq - \frac{\eta^2}{2\sigma^2 C \Delta} \xrightarrow{\Delta \to 0} -\infty.
\]

It is clear that the same result remains valid for \( \theta = \inf \{ t : -N^K_{t,C} \geq \eta \}. \) Combining both, we obtain \( 5.7. \)

\( \textbf{(ii)-Verification. The upper bound.} \) For \( u_0 \neq 1 \) or \( du_t \not\ll dt, \) the proof is obvious. For \( u_0 = 1 \) and \( du_t = \dot{u}_t dt, \) the stochastic exponential technique is applicable. With an absolutely continuous deterministic function \( \lambda(t) \) let us introduce a continuous martingale \( M_t \) and its predictable variation process \( \langle M \rangle_t: \)

\[
M_t = \frac{\sigma}{\sqrt{K}} \int_0^t \lambda(s) \sqrt{x^K_s} \, dB_s \quad \text{and} \quad \langle M \rangle_t = \frac{\sigma^2}{K} \int_0^t \lambda^2(s)x^K_s \, ds.
\]

It is well known that the stochastic exponential \( \tilde{M} = e^{M_t - 0.5 \langle M \rangle_t} \) is a local martingale and a supermartingale too with \( \mathbb{E} \tilde{M} \leq 1. \) The use of this property implies

\[
1 \geq \mathbb{E} I_{\{ \sup_{s \leq T} |x^K - u_t| \leq \delta \}} \tilde{M}.
\]

\[
1 \geq \mathbb{E} I_{\{ \sup_{s \leq T} |x^K - u_t| \leq \delta \}} \tilde{M} - \mathbb{E} I_{\{ \sup_{s \leq T} |x^K - u_t| \geq \delta \}} \tilde{M}.
\]
The next helpful step of the proof gives a deterministic lower bound for $\lambda_T$ on the set $\{ \sup_{t \leq T} |x_t^K - u_t| \leq \delta \} =: \mathcal{A}_\delta$. By (5.8), $M_t = \int_0^t \lambda(s)(dx_s^K - \alpha x_s^K ds)$, so that,

$$\log \lambda_T = \int_0^T \lambda(s)(dx_s^K - \alpha x_s^K ds) - \frac{\sigma^2}{2K} \int_0^T \lambda^2(s)x_s^K ds$$
$$= \int_0^T \left[ \lambda(s)(\dot{u}_s - \alpha u_s ds) - \frac{\sigma^2}{2K} \lambda^2(s)u_s \right] ds$$
$$+ \int_0^T \lambda(s)d(x_s^K - u_s) \geq \lambda_T(x_T^K - u_T) - \int_0^T (x_s^K - u_s)\dot{\lambda}_t ds$$
$$- \int_0^T \left[ \lambda(s)\alpha \{ x_s^K - u_s \} + \frac{\sigma^2}{2K} \lambda^2(s)\{ x_s^K - u_s \} \right] ds.$$

Now, by taking $\lambda(s) = K\theta(s)$, we find a lower bound of $\lambda_T$ on the set $\mathcal{A}_\delta := \{ \sup_{t \leq T} |x_t^K - u_t| \leq \delta \}$,

$$\log \lambda_T \geq K \int_0^T \left[ \theta(s)(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \theta^2(s)u_s \right] ds$$
$$- \delta K \left[ |\theta_T| + \int_0^T \left( |\dot{\theta}_s| + |\alpha \theta(s)| + \frac{\sigma^2}{2} \theta^2(s) \right) ds \right].$$

This lower bound jointly with (5.8) implies the following upper bound: for any absolutely continuous deterministic function $\theta(s)$,

$$\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\mathcal{A}_\delta) \leq - \int_0^T \left[ \theta(s)(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \theta^2(s)(u_s + \epsilon) \right] ds.$$

Since $u_s$ is only nonnegative, it makes sense, for computational convenience, to use a corrected upper bound, with $\epsilon > 0$

$$\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\mathcal{A}_\delta) \leq - \int_0^T \left[ \theta(s)(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \theta^2(s)(u_s + \epsilon) \right] ds. \quad (5.9)$$

If $\dot{u}_t$ is absolutely continuous function, a choice of $\theta(s) = \frac{\dot{u}_s - \alpha u_s}{\sigma^2(u_s + \epsilon)}$ provides

$$\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\mathcal{A}_\delta) \leq - \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_s - \alpha u_s)^2}{u_s + \epsilon} ds$$
$$- \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_s - \alpha u_s)^2}{u_s} ds, \quad \epsilon \downarrow 0.$$

In general case, one can choose a sequence $\theta_n(s), n \geq 1$ of absolutely continuous functions such that

$$\lim_{n \to \infty} \left[ \theta_n(s)(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \theta_n^2(s)(u_s + \epsilon) \right] = \sup_{\phi \in \mathbb{R}} \left[ \phi(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \phi^2(u_s + \epsilon) \right]$$
$$= \frac{1}{2\sigma^2} \frac{(\dot{u}_s - \alpha u_s)^2}{u_s + \epsilon}.$$

Hence, for sufficiently large $n$, $\left[ \theta_n(s)(\dot{u}_s - \alpha u_s ds) - \frac{\sigma^2}{2} \theta_n^2(s)(u_s + \epsilon) \right] \geq 0$. Then, due to (5.9) being valid with $\theta(s)$ replaced by $\theta_n(s)$, and Fatou’s theorem, we find
that
\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\mathcal{A}_\delta) \leq - \lim_{n \to \infty} \int_0^T \left[ \theta_n(s)(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \theta_n^2(s)(u_s + \varepsilon) \right] ds
\]
\[
\leq - \int_0^T \lim_{n \to \infty} \left[ \theta_n(s)(\dot{u}_s - \alpha u_s) - \frac{\sigma^2}{2} \theta_n^2(s)(u_s + \varepsilon) \right] ds = - \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_s - \alpha u_s)^2}{u_s} ds,
\]
\[
\varepsilon \to 0.
\]

(ii)-Verification. The proof of
\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left( \sup_{t \leq T} |x^K_t - u_t| \leq \delta \right) \geq - \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_t - \alpha u_t)^2}{u_t} dt
\]
(5.10)
is done in three steps.

1. It suffices to analyse the case \( \int_0^T \frac{(\dot{u}_s - \alpha u_s)^2}{u_s} ds < \infty \), which enables us to consider only those test functions that remain zero after arriving at zero. In other words, we shall give the proof of (5.11) for absolutely continuous \( u \) with \( u_0 = 1 \) and \( (u_t > 0)_{t \in T}, u_T \geq 0 \).

2. Set \( \tau_C = \inf \{ t \leq T : x^K_t \geq C \} \), where \( \inf \{ \emptyset \} = \infty \) and notice that if for any \( C > 0 \)
\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P\left( \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \right) \geq - \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_t - \alpha u_t)^2}{u_t} dt,
\]
(5.11)
then (5.10) holds. This can be seen as follows. Since
\[
\mathcal{A}_\delta \supseteq \left\{ \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \right\} \cap \{ \tau_C = \infty \}
\]
\[
= \left\{ \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \right\} \setminus \left\{ \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \right\} \cap \{ \tau_C \leq T \},
\]
we have \( \{ \tau_C \leq T \} \cup \mathcal{A}_\delta \supseteq \{ \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \} \), so that,
\[
2 \left[ P(\mathcal{A}_\delta) \lor P(\tau_C \leq T) \right] \geq P\left( \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \right).
\]

Hence, due to (5.11),
\[
\lim_{\delta \to 0} \lim_{K \to \infty} \frac{1}{K} \log P(\mathcal{A}_\delta) \lor \lim_{C \to \infty} \lim_{K \to \infty} \frac{1}{K} \log P(\tau_C \leq T)
\]
\[
\geq - \frac{1}{2\sigma^2} \int_0^T \frac{(\dot{u}_t - \alpha u_t)^2}{u_t} dt
\]
and it is left to recall that \( \{ \tau_C \leq T \} = \{ \sup_{t \leq T} x^K_t \geq C \} \) and to refer to (5.11).

3. By 1., \( \int_0^T \dot{u}_t^2 dt < \infty \). We proceed with the verification of (5.11). Define a continuous martingale \( M_t \) and its variation process \( \langle M \rangle_t \): with \( \varepsilon > 0 \),
\[
M_t = \int_0^{t \wedge \tau_C} \sqrt{K} \frac{\dot{u}_s - \alpha x^K_s}{\sigma \sqrt{x^K_s + \varepsilon}} dB_s \quad \text{and} \quad \langle M \rangle_t = \int_0^{t \wedge \tau_C} K \frac{(\dot{u}_s - \alpha x^K_s)^2}{\sigma^2 (x^K_s + \varepsilon)} ds.
\]
By definition of \( \tau_C \), we have \( \langle M \rangle_T \leq \frac{2K}{\sigma^2} \int_0^T (\dot{u}_s^2 + \alpha^2 C^2) ds < \infty \), so that the stochastic exponential \( (\delta_t, \mathcal{F}_t^\varepsilon, P)_{t \leq T} \) with \( \delta_t = e^{\langle M_t \rangle_r - 0.5 \langle M \rangle_t} \), is a uniformly integrable martingale, \( E_{\mathcal{F}_T} = 1 \). We use the latter property to define a new probability measure \( \tilde{P} \) on \( (\Omega, \mathcal{F}_T^\varepsilon) \) by letting \( d\tilde{P} = \delta_T dP \) and apply
\[
P\left( \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \right) = \int_{\{ \sup_{t \leq T \wedge \tau_C} |x^K_t - u_t| \leq \delta \}} \delta_T^{-1} d\tilde{P}.
for verification of \((5.11)\). This approach heavily uses a semimartingale description of the processes \((x_t^K, \mathcal{F}_t^B, \tilde{\mathbb{P}})_{t \leq T}\) and \((\tilde{y}_t^L, \mathcal{F}_t^B, \tilde{\mathbb{P}})_{t \leq T}\). We begin with the process \((B_t, \mathcal{F}_t^B, \tilde{\mathbb{P}})_{t \leq T}\). The random processes \((B_t, \mathcal{F}_t^B, \tilde{\mathbb{P}})_{t \leq T}\) and \((\tilde{y}_t^L, \mathcal{F}_t^B, \tilde{\mathbb{P}})_{t \leq T}\) are continuous martingales and, in particular,

$$
    d\tilde{y}_t = I_{(\tau_C \geq t)} \sqrt{K} \frac{\bar{u}_s - \alpha x_t^K}{\sigma \sqrt{x_t^K + \varepsilon}} dB_t.
$$

Hence, the co-variation process for \(\tilde{y}_t, B_t\) is defined as:

$$
    \langle \tilde{y}, B \rangle_t = \int_0^t \sqrt{K} \frac{\bar{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, ds.
$$

It is well known (see, e.g., Ch. 4, §5 in [10]) that the random process \((\tilde{B}_t, \mathcal{F}_t^B, \tilde{\mathbb{P}})_{t \leq T}\) with

$$
    \tilde{B}_t = B_t - \int_0^t \sqrt{K} \frac{\bar{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, ds
$$

is a Brownian motion. Consequently, we find that, \(\tilde{\mathbb{P}}\)-a.s.,

$$
    x_t^K = 1 + \int_0^t I_{(\tau_C \geq s)} \hat{u}_s \, ds + \int_0^t \alpha x_s^K \left[ 1 - I_{(\tau_C \geq s)} \left( \frac{x_s^K}{x_s^K + \varepsilon} \right) \right] \, ds
    + \int_0^t \sigma \sqrt{x_s^K} \, d\tilde{B}_s
$$

and

$$
    \log z_t^{-1} = -\int_0^t \sqrt{K} \frac{\hat{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, dB_s - \frac{1}{2} \int_0^t K \left( \frac{\hat{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \right)^2 \, ds.
$$

Now, we evaluate from below the value \(\frac{1}{K} \log \delta_T\) on the set \(\{\sup_{t \leq T \wedge \tau_V} |x_t^K - u_t|\}\). Write

$$
    \frac{1}{K} \log \mathbb{P} \left( \sup_{t \leq T \wedge \tau_C} |x_t^K - u_t| \leq \delta \right) \geq -\frac{1}{2\sigma^2} \int_0^T \frac{(\hat{u}_s - \alpha u_s)^2}{u_s} \, ds + h(C, \varepsilon, \delta)
    - \frac{1}{\sqrt{K}} \sup_{t \leq T} \left| \int_0^t \frac{\hat{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, dB_s \right|,
$$

where \(h(C, \varepsilon, \delta) \to 0\). Therefore, \((5.12)\) can be transformed into (here \(\eta\) is a positive constant)

$$
    \frac{1}{K} \log \mathbb{P} \left( \sup_{t \leq T \wedge \tau_C} |x_t^K - u_t| \leq \delta \right) \geq -\frac{1}{2\sigma^2} \int_0^T \frac{(\hat{u}_s - \alpha u_s)^2}{u_s} \, ds + h(C, \varepsilon, \delta)
    + \frac{1}{K} \log \mathbb{P} \left( \sup_{t \leq T \wedge \tau_C} |x_t^K - u_t| \leq \delta, \frac{1}{\sqrt{K}} \sup_{t \leq T} \left| \int_0^t \frac{\hat{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, dB_s \right| \leq \eta \right).
$$

This lower bound makes it possible to claim that \((5.11)\) holds true, provided that

$$
    \lim_{K \to \infty} \mathbb{P} \left( \sup_{t \leq T} \left| \int_0^t \frac{\hat{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, dB_s \right| > \sqrt{K} \eta \right) = 0 \quad (5.13)
$$

and

$$
    \lim_{\varepsilon \to 0} \lim_{K \to \infty} \mathbb{P} \left( \sup_{t \leq T \wedge \tau_C} |x_t^K - u_t| > \delta \right) = 0. \quad (5.14)
$$

Since \(I_{(\tau_C \geq t)} \frac{(\hat{u}_s - \alpha x_s^K)^2}{\sigma^2 (x_s^K + \varepsilon)} \leq \frac{(|\hat{u}_s| + C)^2}{\sigma^2 \varepsilon}\) the Doob inequality (here \(\mathbb{E}\) is the expectation relative to \(\mathbb{E}\))

$$
    \mathbb{E} \left( \sup_{t \leq T} \left| \int_0^t \frac{\hat{u}_s - \alpha x_s^K}{\sigma \sqrt{x_s^K + \varepsilon}} \, dB_s \right| > \sqrt{K} \eta \right) \leq \frac{4}{K \eta^2} \int_0^T \frac{(|\hat{u}_s| + C)^2}{\sigma^2 \varepsilon} \, ds,
$$

jointly with 3., establish \((5.12)\).
Due to the first part of (5.12), the proof of (5.14) is reduced to the verification of
\[
\lim_{\varepsilon \to 0} \sup_{0 \leq x \leq C} \left[ 1 - \left( \frac{x}{x + \varepsilon} \right)^{0.5} \right] = 0,
\]
which is obvious, and
\[
\lim_{K \to \infty} \overline{P} \left( \sup_{t \leq T} \left| \int_0^{t \wedge \tau_C} \sqrt{x^K_s dB_s} > \sqrt{K \eta} \right| \right) = 0,
\]
which is similar to the proof of (5.13).
