Introduction

Share-wave elastography (SWE) is based on the principle of acoustic radiation force produced by the ultrasound (US) probe. Transversely oriented shear-waves are generated by the acoustic radiation force and used to induce tissue deformation [1]. SWE measures the shear-wave propagation speed and displays the quantitative data as a color-coded image in real time. Waves propagate faster in hard tissue than soft tissue and SWE is proved useful in improving the specificity of US evaluation of BI-RADS 3 and 4a breast lesions, including complicated cysts [2]. We report the shear-wave direct visualisation on a gray-scale image and discuss its possible implication.

Case report

A 39 year old female patient, with known fibrocystic breast disease presented with a left painful breast lump. The patient underwent a breast ultrasound that depicted a complicated cyst with a “pseudo-solid” content. When the SWE mode was turned on, the ultrasound shear wave was observed on the gray-scale image, as surface undulations of the “pseudo-solid” component. To the best of our knowledge, this is the first report of the shear wave visualization on a gray-scale image. The impact on patient management is discussed.

Keywords: shear wave; breast elastography; complicated cyst
mon gray-scale appearance with a rhythmical throbbing or vibrating movements, similar to an arterial pulsation (fig 2, supplementary video 1, on the journal site).

Both color and Power Doppler were still negative. The overall US findings were categorised as BIRADS 2. The patient underwent cyst aspiration and its entire content was completely evacuated (fig 3).

**Discussion**

Strain elastography was the first method used in clinical practice to assess the tissue stiffness. Several studies have already shown that is a useful tool in the diagnosis and characterization of breast lesions [1,3]. Furthermore, the vast user experience in strain elastography has lead to the discovery of numerous and well-described artifacts and pitfalls [4].

SWE, a relatively new elastography technique, is divided in two types: point shear-wave speed measurement and shear-wave speed imaging. Thereby, as new technologies emerge, new imaging findings, artifacts and pitfalls need to be reported as in the case of strain elastography.

A study reported that SWE improves the specificity of US evaluation of BI-RADS 3 and 4a lesions and included complicated cysts among examined lesions [2], but offered no other comments regarding shear-wave imaging [2]. The latest WFUMB guidelines suggest that, in cystic lesions, SWE examination deserves a special attention as fluids do not support shear-waves and so cysts appear as colour voids [5]. When the fluid is more viscous, SWE may display soft regions.

Recent papers identify, describe and explain technical restrictions and artifacts encountered in 2D-SWE that may alter the appropriate diagnostic and therapeutic patient management [5,6]. Few of them are found only on Supersonic machine [7,8].

Our case highlighted a new, to the best of our knowledge, unreported SWE imaging aspect, due to an expected physic phenomenon. The peculiar gray-scale appearance might be explained by the wave interference phenomenon, by which two waves superpose, forming a resultant wave of higher, lower, or equal amplitude. In our case, this translates into a rhythmical pulsation of the medium. Nothing but the debris was responsible for causing the phenomenon, as in pure transonic or completely impure cysts, the phenomenon was not seen.

For an unexperienced breast radiologist, this SWE appearance could erroneously indicate a vascularized mass. When using Supersonic SWE to evaluate the stiffness of a supposably intracystic mass, the users need to be aware of this normal phenomenon and must not rec-
ommend a biopsy, unless the lesion is investigated by other complementary ultrasound modes (2D gray-scale, color or cower Doppler) and is categorized as suspect (BIRADS 4 or 5).

In conclusion we present the first gray-scale image of shear-wave visualization together with its important clinical implications. As a future direction, it remains to be established if the share-wave visualization is linked only to Supersonic or it may be observed using other manufacturers’ machines.
