**Abstract**

Taxonogenomics coupled with culturomics promotes the isolation and characterization of bacteria. *Kallipyga gabanensis* sp. nov. strain GM4 is a strictly anaerobic, Gram-positive, and non motile coccus isolated from the stool of a Gabonese male teenager. The genome is 1,621,211 bp long with 50.01% G+C content and two scaffolds. Of the 1,536 predicted genes, 1,475 were protein-coding genes and 61 were RNA genes. A total of 931 genes were assigned a putative function, and 79 genes were identified as ORFans.

**Introduction**

Bacteraemia represents an important cause of infectious diseases throughout the world [1]. It is mainly the consequence of the destruction of the gastrointestinal barrier by some factor, principally infectious factors [2]. In 1997 Wilairatana et al. [2] reported that gastrointestinal permeability is increased during *Plasmodium falciparum* malaria but reverts to normal during convalescence. This knowledge highlighted the need to perform an exhaustive study of the microorganisms existing in the human gut. Overall, 1 g of human stool contains between 1011 and 1012 bacteria [3]; unfortunately, only approximately 2000 different bacteria are known of the human microbiota. This number remains insufficient as a result of the lack of comprehensive culture methods. To enhance the isolation of bacteria, our laboratory performed an efficient method called culturomics [4]. Since then, several new bacteria, including new genera and species, have been reported in the human gut [5–8].

To describe these bacteria, 16S ribosomal RNA sequencing coupled with a taxonogenomic strategy was recently developed. This strategy is based on a systematic comparison of genomic and phenotypic characteristics, especially the matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF) spectrum, with the phylogenetically closest species existing in databases [5–8].

Using the culturomics method, a new bacterium was isolated from a healthy Gabonese male teenager. The strain exhibited 97.9% of similarity with the 16S nucleotide sequence of *Kallipyga massiliensis* (JN837487). However, this value was lower than the 98.7% 16S rRNA gene sequence threshold recommended by Stackebrandt and Ebers [9] to delineate a new species without carrying out DNA-DNA hybridization.

Here we present methods of isolation and characterization of *Kallipyga gabanensis* sp. nov. strain GM4 (= CSUR P1915 = DSM 100575), followed by its classification and a set of
features including a description of the complete genome sequencing and annotation.

Material and Methods

Ethics and sample collection
After receiving signed informed consent, a stool specimen was collected at Lebamba, Gabon, in January 2015. This study had been previously approved by the National Ethic Committee of Gabon and IFR48, Marseille, France (0023/2013/SG/CNE and 09-022, respectively). The specimen was from a healthy Gabonese male 16-year-old (body mass index, 19.03 kg/m²) who belonged to the Nzebi tribe of Gabon. The stool sample was stored at −80°C until it was sent to URMITE (Marseille, France) for analysis.

Strain isolation
The stool sample was diluted in phosphate-buffered saline (Life Technologies, Carlsbad, CA, USA) in April 2015. The inoculum was obtained and preincubated in anaerobic conditions at 37°C in a culture bottle containing a blood-enriched Columbia agar liquid medium (bioMérieux, Marcy l’Étoile, France). After pre-incubation, 100 μL of cultured media was recovered, diluted and incubated 24 or 48 hours on a 5% sheep’s blood–enriched Columbia agar solid medium (bioMérieux) at 37°C in the anaerobic conditions of the generator (GENbag anær; bioMérieux). The colonies of bacteria obtained were isolated on 5% sheep’s blood–enriched Columbia agar (bioMérieux). They were then identified using MALDI-TOF and 16S rRNA sequencing [5–8].

MALDI-TOF and 16S rRNA identification
In order to identify bacteria, MALDI-TOF was used following the same protocol as previously described [5–8]. Identification of bacteria continued with a 16S rRNA standard PCR coupled with sequencing. The apparatuses used were GeneAmp PCR System 2720 thermal cyclers (Applied Biosystems, Foster City, CA, USA) and the ABI Prism 3130xl Genetic Analyzer capillary sequencer (Applied Biosystems), respectively [10]. The 16S rRNA nucleotide sequence obtained after amplification and sequencing was corrected using Chromas Pro 1.34 software (Technelysium, Tewantin, Australia). Then a BLASTN was systematically performed in the online PubMed National Center for Biotechnology Information (NCBI) database (http://blast.ncbi.nlm.nih.gov/galaxy/blast.cgi). The spectrum of K. gabonensis strain GM4 was entered in the Bruker database, and its 16S rRNA sequence was deposited in GenBank under accession number LN849790. Sequences were aligned using CLUSTALW, and phylogenetic inferences were obtained using the maximum-likelihood method within MEGA software [5–8].

Growth conditions
The growth temperature of K. gabonensis strain GM4 was assessed by cultivating this bacterium on 5% sheep’s blood–enriched Colombia agar (bioMérieux) in anaerobic conditions. Four growth temperatures were tested: 28, 37, 45 and 55°C. The GENbag anær and GENbag microaer systems (bioMérieux) were used to assess the ability of the bacterium to grow anaerobically or in microaerophilic conditions, respectively, at 37°C. The limit of salinity’s acceptance of K. gabonensis strain GM4 was tested using 0, 5, 15 and 45% NaCl concentrations. Accordingly, three pHs were tested: 5, 7 and 8.5.

Biochemical, sporulation and motility assays
API ZYM, API 20A and API 50CH (bioMérieux) gallery systems were used to perform biochemical assays. The sporulation test was done with a thermic shock (80°C during 10 minutes). To evaluate the motility of K. gabonensis strain GM4, fresh colonies were observed between blades and slats using a DM1000 photonic microscope (Leica Microsystems, Nanterre, France) with a 40× objective lens.

Antibiotic susceptibility
Sixteen antibiotics were used to test antibiotic susceptibility of the bacterium. They included amoxicillin, doxycycline, nitrofurantoin, vancomycin, amoxicillin/clavulanic acid, clindamycin, rifampicin, gentamicin, tobramycin, erythromycin, metronidazole, trimethoprim/sulfamethoxazole, amikacin, ciprofloxacin, imipenem/cilastatin and oxacillin (i2a, Montpellier, France).

Microscopy
Images of K. gabonensis strain GM4 were obtained using a Tecnai G20 transmission electron microscope (FEI, Limel-Brevannes, France) at an operating voltage of 60 kV. Gram staining was observed using a DM1000 photonic microscope (Leica Microsystems) with a 100× oil-immersion objective lens.

Genome sequencing and assembly
A MiSeq sequencer (Illumina, San Diego, CA, USA) added to the mate-pair strategy was used to sequence the genomic DNA (gDNA) of K. gabonensis strain GM4. gDNA was barcoded to allow mixing with 11 other projects by using the Nextera Mate-Pair sample prep kit (Illumina). The mate-pair library was prepared with 1 μg of gDNA using the Nextera Mate-Pair Illumina guide. The gDNA sample was fragmented and tagged using a mate-pair junction adapter. Validation of the pattern of fragmentation was done with a DNA 7500 labchip on an Agilent 2100 BioAnalyzer (Agilent Technologies, Santa Clara, CA, USA). The size of the DNA fragments ranged from 1 to 10 kb, with an optimal size of 4.08 kb. There was no size selection, and only 464 ng of tagmented fragments were circularized. The
circularized DNA was mechanically sheared to small fragments (optimal at 569 bp) in microtubes by using the Covaris S2 ultrasonicator (Covaris, Woburn, MA, USA). The profile of the library was visualized on a High Sensitivity Bioanalyzer LabChip (Agilent Technologies). The final library concentration was measured at 24.4 nmol/L, normalized at 2 nM and pooled. The library pool was loaded onto the reagent cartridge and then onto the instrument along with the flow cell after a denaturation step and dilution at 15 pM. Cluster generation and the sequencing run were automatically performed in a single 39-hour run in 2 × 251 bp. From a 1189K/mm² cluster density and a cluster passing quality control filters of 99.1% (22,579,000 clusters), 10.1 GB of information was obtained. The reads obtained were trimmed; assembly was then performed using the CLC genomicsWB4 software [5–8].

Genome annotation and comparison
Prodigal software (http://prodigal.ornl.gov/) adjusted with default parameters was used to predict open reading frames (ORFs), and the predicted ORFs were excluded if they spanned a sequencing gap region. The predicted bacterial protein sequences were searched against the GenBank [11] and Clusters FIG. 1. Reference mass spectrum (matrix-assisted laser desorption/ionization time-of-flight mass spectrometry, MALDI-TOF) from Kallipyga gabonensis strain GM4. Spectra from 12 individual colonies were compared and reference spectrum generated.

FIG. 2. Phylogenetic tree highlighting position of Kallipyga gabonensis strain GM4 compared to other Clostridiales bacteria. Sequences were aligned using CLUSTALW and phylogenetic inferences obtained using maximum-likelihood method within MEGA software. Scale bar = 0.05% nucleotide sequence divergence.
Homemade average genomic identity of orthologous gene sequences (AGIOS) software was used to estimate the mean level of nucleotide sequence similarity between \textit{K. gabonensis} and other \textit{Clostridiales} [21]. By combining AGIOS and Protei-northo software [22], we detected orthologous proteins between genomes compared two by two. The corresponding genes were then retrieved, and the mean percentage of nucleotide sequence identity among orthologous ORFs was determined using the Needleman-Wunsch global alignment algorithm. To make a genome comparison, \textit{K. gabonensis} strain GM4 was compared with \textit{Desulfitobacterium hafniense} strain DP7, \textit{Peptostreptococcaceae bacterium} strain VA2, \textit{Fusobacterium nucleatum} strain 36A2, \textit{Kallipyga massiliensis} strain ph2 and \textit{Clostridiales bacterium} strain 9403326.

All annotation and comparison processes were done via the Multi-Agent Software System DAGOBAH [23] that includes Figenix [24].

### Results and Discussion

**MALDI-TOF and phylogenetic analysis**

The spectrum generated from clean \textit{Kallipyga gabonensis} strain GM4 spots was unable to match those of the Bruker database (Fig. 1). Using 16S rRNA phylogeny analysis, we demonstrated that \textit{K. gabonensis} strain GM4 exhibited 97.9% similarity with the 16S nucleotide sequence of \textit{K. massiliensis} (JN837487) (Fig. 2). This value of similarity remains lower than the 98.7% 16S rRNA gene sequence threshold recommended by Stackebrandt and Ebers [9] to delineate a new species without
carrying out DNA-DNA hybridization. Thus, this bacterium was considered to be a new species called *K. gabonensis* sp. nov. strain GM4 belonging to the *Clostridiales Incertae Sedis XI* family created in 2009 [25] (Table 1). The 16S rRNA sequence of *Kallipyga gabonensis* was 1,486 bp long (LN 849790). The 16S rRNA gene was amplified using PCR with the universal primer pair fD1 and rP2. The sequences reactions were performed with the 536F, 536R, 1050F, 1050R, 800F and 800R primers as previously described [4]. *Clostridiales Incertae Sedis XI* is a heterogeneous group that includes anaerobic and morphologically variable bacteria. It currently comprises 11 genera, including *Anaerococcus*, *Peptoniphilus* and *Tissierella*. The new genus *Kallipyga*, belonging to this group, was recently created in 2013 and included to date only one species, *Kallipyga massiliensis* [26]. The definition of *Clostridiales Incertae Sedis XI* is mainly based on phylogenetic analyses of 16S rRNA sequences, and its members have no precise taxonomic or phylogenetic affiliation. A gel view was performed in order to see the spectra differences of *Kallipyga gabonensis* with other close bacteria, including the second species of the *Kallipyga* genus (*K. massiliensis*) (Fig. 3). The 16S rRNA sequence of *K. gabonensis* was deposited in GenBank under accession number LN849790.

**Phenotypic and biochemical characterization**

*K. gabonensis* sp. nov. strain GM4 is Gram positive, comprises non motile cocci, and is non-spore forming (Fig. 4). This bacterium is catalase positive and oxidase negative. It is able to grow under temperatures ranging from 28 to 45°C, with an optimum growth at 37°C, after 48 hours of culture. pH test results showed that *K. gabonensis* can survive under pH conditions ranging between 5 and 8.5, but has optimal growth at pH 5. It grows better with salinity concentrations of around 0. Individual colonies of *K. gabonensis* are whitish and exhibit a diameter of 2 mm on 5% sheep’s blood–enriched Colombia agar. Its individual cell exhibits a diameter of 0.6 μm in electron microscopy (Fig. 5). Furthermore, this bacterium is strictly anaerobic; it is unable to grow in aerobic and microaerophilic atmospheres.

Using the API 20A gallery, positive reactions were observed for d-glucose and esculin ferric citrate. Using API 50CH, we concluded that *K. gabonensis* is able to ferment esculin ferric.

**TABLE 2. Differential characteristics of *Kallipyga gabonensis* strain GM4 (data from this study) with *Kallipyga massiliensis* strain ph2 [26], *Fenollaria massiliensis* strain 9401234(T) [29] and *Anaerococcus senegalensis* strain JC48T [5]**

citrate (as found with the API 20A gallery), D-melibiose, sucrose, inulin and D-raf\nfinose. The result of the API ZYM gallery shows that K. gabonensis possesses esterase (C4), leucine arylamidase, naphthol-AS-BI-phosphohydrolase, slightly esterase lipase (C8), acid phosphatase and β-glucosidase activities. All biochemical reactions not listed here but present in the three galleries we used remained negative. These biochemical characteristics were compared with those of other close bacteria (Table 2). Among the antibiotics tested, K. gabonensis was sensitive only to metronidazole, imipenem and oxacillin. No sensitivity was recorded with amoxicillin, doxycycline, nitrofurantoin, vancomycin, amoxicillin/clavulanic acid, clindamycin, erythromycin, tobramycin, trimethoprim, amikacin, ciprofloxacin 5 and gentamicin.

**Genome properties**

The genome is 1,621,211 bp long with 50.01% G+C content (Table 3). It contains two scaffolds (composed of two contigs) (Fig. 6). Of the 1,536 predicted genes, 1,475 were protein-coding genes and 61 were RNA genes (four are 5S rRNA, four are 16S rRNA, four are 23S rRNA, 49 are tRNA genes). A total of 931 genes (63.12%) were assigned a putative function (by COGs or by nrBLAST), and 79 genes were identified as ORFans (5.36%). The remaining genes were annotated as encoding hypothetical proteins (394 genes = 26.71%). Table 4 summarizes the distribution of genes into COGs functional categories of the K. gabonensis genome. The genome sequence has been deposited in GenBank under accession number CXYV00000000.

Genome comparison

The draft genome sequence of *Kallipyga gabonensis* strain GM4 (1.62 Mb) is lower than those of *Desulfitobacterium hafniense* strain DP7 (5.73 Mb), *Peptostreptococcaceae bacterium* strain VA2 (3.58 Mb), *Fusobacterium nucleatum* strain 36A2 (2.17 Mb), *Kallipyga massiliensis* strain GM4 (1.71 Mb). The G+C percentage of *K. gabonensis* strain GM4 (50.0%) is lower than that of *Kallipyga massiliensis* strain ph2 (51.4%) but higher than those of *Clostridiales bacterium* strain 9403326, *Desulfitobacterium hafniense* strain DP7, *Peptostreptococcaceae bacterium* strain VA2, and *Fusobacterium nucleatum* (48.8, 47.4, 28.6 and 27.2% respectively). The gene content of *K. gabonensis* strain GM4 (1536) is lower than those of *Clostridiales bacterium* strain GM4 (1475) and *Kallipyga massiliensis* strain ph2 and *Clostridiales bacterium* strain 9403326 (5,365, 3,567, 2,062, 1,616 and 1,538, respectively). The protein-coding genes of *Kallipyga gabonensis* strain GM4 (1475) are more numerous than in *Clostridiales bacterium* strain 9403326 (1,463) and less numerous than those of *Desulfitobacterium hafniense* strain DP7, *Peptostreptococcaceae bacterium* strain VA2, *Fusobacterium nucleatum* strain 36A2 and *Kallipyga massiliensis* strain ph2 (5,203, 3,193, 1,983 and 1,546, respectively). Specifically in comparison with *Kallipyga massiliensis*, the genome of *K. gabonensis* includes a larger number of genes assigned with peptide signals (153 vs. 90), a larger number of ORFans (79 vs. 42) and a larger number of RNA genes (61 vs. 50) but a lower number of genes assigned to COGs (913 vs. 1165).

Among the species with standing in nomenclature, AGIOS values ranged from 85.78 between *Kallipyga gabonensis* strain GM4 and *Kallipyga massiliensis* strain ph2 to 51.41 between *Kallipyga massiliensis* strain ph2 and *Fusobacterium nucleatum* strain 36A2. The AGIOS strategy involves the first step of performing proteinOrtho analysis to identify the group of orthologous genes. Then for each couple of orthologous genes in each couple of genomes, an alignment at the nucleotide level is done, and a similarity score is calculated for each couple of orthologous genes. For each couple of genomes, a mean similarity score is defined.

To evaluate the genomic similarity among the studied strains, we determined two parameters, digital DNA-DNA hybridization (DDH), which exhibits a high correlation with DDH [27,28] and AGIOS [21], which was designed to be independent from DDH. As a result of recent innovations, the area of genome sequencing called for bioinformatics methods to replace the wet-lab DDH by in silico genome-to-genome comparison. This is the method for inferring whole-genome distances which are well able to mimic DDH. These distance functions can also cope with heavily reduced genomes and repetitive sequence regions. Some of them are also very robust against missing fractions of genomic information (which may result from incomplete genome sequencing). This digitally derived genome-to-genome distance shows a better correlation with 16S rRNA gene sequence distances than DDH values.

TABLE 5. Numbers of orthologous proteins shared between genomes (upper right)*

|                | Clostridiales bacterium | Desulfitobacterium hafniense | Kallipyga gabonensis | Kallipyga massiliensis | Peptostreptococcaceae bacterium | Fusobacterium nucleatum |
|----------------|-------------------------|--------------------------------|----------------------|------------------------|--------------------------------|-------------------------|

The distribution of functional classes of predicted genes according to the clusters of orthologous groups of proteins is summarized in Table 5 and Fig. 7. Table 6 summarizes the pairwise comparison of Kallipyga gabonensis with other species using the Genome-to-Genome Distance Calculator.

Conclusion

On the basis of phenotypic, phylogenetic and genomic analyses, we formally propose the creation of Kallipyga gabonensis sp. nov., which contains the strain GM4. This bacterium was isolated in Marseille (France) from a stool specimen of a healthy Gabonese male youth.

Description of Kallipyga gabonensis sp. nov.

Kallipyga gabonensis (ga.bon.en’sis. L. masc. n. gabonensis, for Gabon, where the specimen was collected). A non motile, Gram-positive cocci. K. gabonensis is catalase positive and oxidase negative, non-spore forming, strictly anaerobic, and has an exhibited individual cell with a diameter of 0.6 µm. Colonies of K. gabonensis are whitish and exhibit a diameter of 2 mm. Maximal growth was recorded at 37°C, with a pH of 5 and a salinity concentration around 0. K. gabonensis was sensitive to metronidazole, imipenem and oxacillin. Using API gallery systems, K. gabonensis strain GM4 induced positive reactions with D-glucose, esculin ferric citrate, D-melibiose, sucrose, inulin and D-raf

Table 6. Pairwise comparison of Kallipyga gabonensis with other species

|                         | Clostridiales bacterium | Desulftobacterium hafniense | Kallipyga gabonensis | Kallipyga massiliensis | Peptostreptococcaceae bacterium | Fusobacterium nucleatum |
|-------------------------|-------------------------|-----------------------------|----------------------|-----------------------|--------------------------------|-------------------------|
| Clostridiales bacterium | 100% ± 00               | 20.8% ± 2.52                | 21.2% ± 2.53         | 29.7% ± 2.56          | 22.9% ± 2.53                   | 20% ± 2.52              |
| Desulftobacterium hafniense | 100% ± 00                | 21.7% ± 2.52                | 21.4% ± 2.52         | 23.4% ± 2.53          | 18.9% ± 2.52                   | 17.9% ± 2.52            |
| Kallipyga gabonensis    | 100% ± 00                | 30.1% ± 3.12                | 21.4% ± 2.54         | 17.9% ± 2.52          | 17.3% ± 2.52                   | 17.7% ± 2.54            |
| Kallipyga massiliensis  | 100% ± 00                | 21.2% ± 2.53                | 21.2% ± 2.53         | 17.9% ± 2.52          | 17.3% ± 2.52                   | 17.7% ± 2.54            |
| Peptostreptococcaceae bacterium | 100% ± 00                  |                            | 21.2% ± 2.53         | 17.9% ± 2.52          | 17.3% ± 2.52                   | 17.7% ± 2.54            |
| Fusobacterium nucleatum | 100% ± 00                |                            | 21.2% ± 2.53         | 17.9% ± 2.52          | 17.3% ± 2.52                   | 17.7% ± 2.54            |

DDH, DNA-DNA hybridization; GGDC, Genome-to-Genome Distance Calculator; HSP, High-scoring Segment Pair.

*aData were generated by GGDC, formula 2 (DDH estimates based on identities/HSP length). Confidences intervals indicate inherent uncertainty in estimating DDH values from intergenic distances based on models derived from empirical test data sets (which are always limited in size). These results are in accordance with 16S rRNA (Fig. 2) and phylogenomic analyses as well as GGDC results.*
